Concern of global warming, reducing energy consumption and using clean sources, which architects play a significant role to achieve, became more and more significant. Therefore recognition and development of new materials and their features and know how to optimum their properties or by integration of the systems they can provide significant solution for architectural demand. In architecture the use of new materials is limited, despite the fact that new materials are capable of wide range of applications. Proper selection of the materials can effectively increase the level of energy efficiency of buildings. Integration of recombinant materials with building systems will provide a great potential for innovation in architectural field. It can result in providing desirable condition for inhabitant. Solar selective glasses such as electrochromic and thermochromic manage both of the solar heat gain and adequate day light .integrate suitable coatings with the glasses enhance the performance. Thermoelectric integrated with solar cells will be more efficient and can

be applied on roof and building facade. The purpose of using thermoelectric film on glass louver is the potential of producing energy from solar source; in addition, heat waste could be convert to electricity. The glass louvers mentioned above are able to change their position based on solar radiation and ambient temperature by using SMA as an actuator. Using PCM in roof, wall, and integrate them with solar cell and glasses such as thermoelectric glasses and the suggestion which was mentioned above lead architects to create energy efficient building. Thus it may be concluded that recombinant materials may bridge contemporary architecture of the world to a more green and energy efficient states.

Keywords: alkali aggregate reaction; fly ash; slag; admixtures

Abstract: The study used the method of accelerated mortar bar test to study alkali aggregate reaction(ASR) with sandstone aggregate. Both fly ash and slag can inhibit the expansion of mortar bar. Results show that 50% slag can inhibit ASR reluctantly, but 10% fly ash and 20% slag can inhibit ASR very well, and the inhibitory effect of fly ash is far better than slag. Because of the high content of CaO in slag, it has inhibit and promote aspects, when the ASR is fierce, slag can inhibit ASR, otherwise slag can promote ASR.

Introduction

Alkali silica reaction (ASR) is a deleterious chemical reaction between alkalis in portland cement paste and certain amorphous silica in a variety of nature aggregate. Numerous concrete structures, such as dams and bridges, have been suffering from ASR[1].

There are so many ways to inhibit the deleterious expansion, but the most effective method is add admixtures, such as fly ash, slag, silica fume, natural zeolite，metakaolin and so on[2].

Papers[2,3] hold the opinion that when the cement is replaced by fly ash by 20%, the deleterious expansion can be constrained availably. And the more the fly ash added, the lower the expansion rate is. Studies[4,5] also indicate that it is an effective mean for controlling expansion due to AAR by blending with steel slag powder. And the amount of slag is always more than 50%.

But if the admixture mix fly ash with slag, can it suppress alkali aggregate reaction better? This is the purpose we design and operate the experiment.

Raw Materials

The cement we used is P Ⅱ 42.5, which brand is lafarge and is made in Dujiangyan city, sichuan province, china. The property is corresponds to the standard *common portland cement* (GB175-2007)[**6**],and alkalinity is 0.56%.

The fly ash and slag are used, the chemical composition is shown in table 1.

Table 1 The chemical composition of fly ash and slag[%]

	SiO_2	Al_2O_3	Fe_2O_3	CaO	MgO	K_2O	Na_2O	Loss
Fly Ash	57.31	32.5	4.89	2.45	0.55	0.76	0.47	2.32
Slag	36.33	10.64	0.79	38.51	8.11	0.51	0.26	

The aggregate is sandstone, which is produced by Ba river, sichuan province, china. Sandstone has potential alkali activity, the activity mainly come from chalcedonic microcrystalline quartz and undulated extinction quartz, the 14d expansion rate is about 0.3% with the test method of accelerate mortar-bar test(AMBT)[7].

Test Methodology

The standard Technical Code for Preventing of Alkali-aggregate Reaction in Concrete (GB/T 50733-2011)[8] is selected and demonstrated. Which operation is almost the same as standard ASTM C1567 test procedure[9].

The size of the specimens are 25mm*25mm*280mm with gage studs at ends, in which the water-to-glue ratio is 0.47, and the aggregate-to-glue ratio is 2.25,by mass. The specimens are cured in 1mol/L sodium hydroxide solution, which is preheated to 80℃.

According to the standard, if the 14d expansion is no more than 0.03%, the suppress is available, the expansion can be calculated by the formulae below:

$$\varepsilon_t = \frac{L_t - L_0}{L_0 - 2\Delta} . \quad (1)$$

There into: ε_t is the expansion ratio of the specimen in the first t days; L_t is the length of the specimen in the first t days; L_0 is the length of the specimen in the first day; Δis the length of the measuring head.

Experiment and Discussion

The inhibition effect of slag on the AAR expansion is shown in Table.2.

Table 2 The effect of different amount of slag on ASR[%]

	3d	7d	10d	14d	21d	28d
30S	0.017452	0.046056	0.075494	0.100921	0.134874	0.163076
40S	0.009948	0.026414	0.047868	0.062767	0.086611	0.105745
50S	0.005083	0.015347	0.027962	0.037023	0.05646	0.073536

S: slag, -30: replacement percentage is 30% by mass.

Figure 1 shows the expansion with the admixture of slag in broken line graphs.

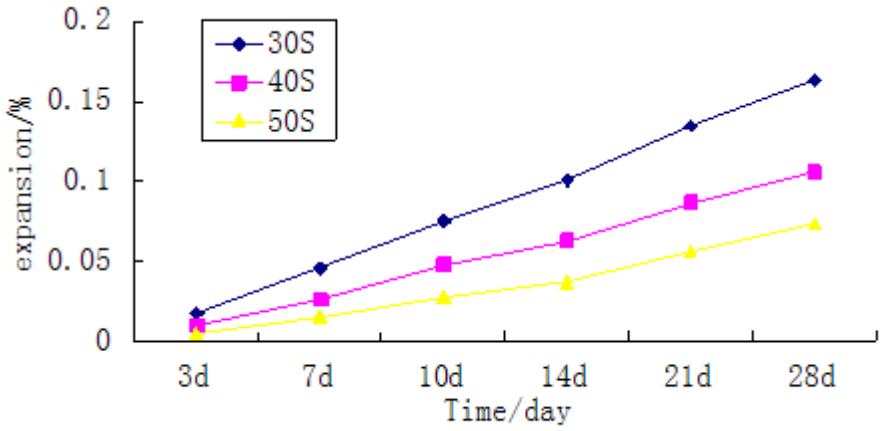

Fig 1 The expansion add slag

It can be seem from Fig.1 that slag can suppress alkali silica reaction. The expansion is decreasing with the increase of slag content., so the slag can restrain ASR.

When the dosages of slag are 30%,40%,50%,the 14d expansions are 0.101%， 0.063 and 0.037% ， although the expansion is decreasing, both of them are greater than 0.03, according to The standard Technical Code for Preventing of Alkali-aggregate Reaction in Concrete (GB/T 50733-2011)[8],the suppress is of no avail, but if we refer to The Standard for Construction Quality Acceptance of Railway Concrete Engineering(TB 10424-2010)[10]， if the 28d expansion is no more than 0.1%,the inhibition is available. Because the 28d expansions are 0.163%, 0.106% and 0.074%, so when the slag replacement ratio is 50%, slag can restrain alkali silica reaction. And conclusion also can be

drawn that the former standard is stricter. It can be forecasted that if the replacement ratio become large, the effect will be better, but study[11] points that when the slag replacement ratio is more than 50%, the concrete strength will decrease significantly, the reason is that the cement content is too low so that the slag can not hydration completely.

No matter how much we replaced, it warn us that, the expansion trend is almost linear, after 28d, the expansion still has a sharp rising trend.

In a word, slag can't restrain ASR very well with the sandstone aggregate. And its effect is far worse than other admixture, such as silica fume, metakaolin[12].

But how does the gel work when it contains fly ash and slag? Table 3 shows the expansion data.

Table 3 The effect of different amount of slag and fly ash on ASR[%]

	1d	3d	7d	10d	14d	21d	28d
10F20S	0.0019	-0.0007	0.0042	0.0059	0.0118	0.0147	0.0128
10F30S	0.0039	0.0009	0.0079	0.0097	0.0181	0.0209	0.0216
20F10S	0.0047	0.0032	0.0103	0.0131	0.0201	0.0264	0.0261
20F20S	-0.0030	-0.0056	0.0008	0.0056	0.0100	0.0128	0.0142

1 S: slag; F: fly ash

To present the result visually, broken line graphs are drawn in figure 2.

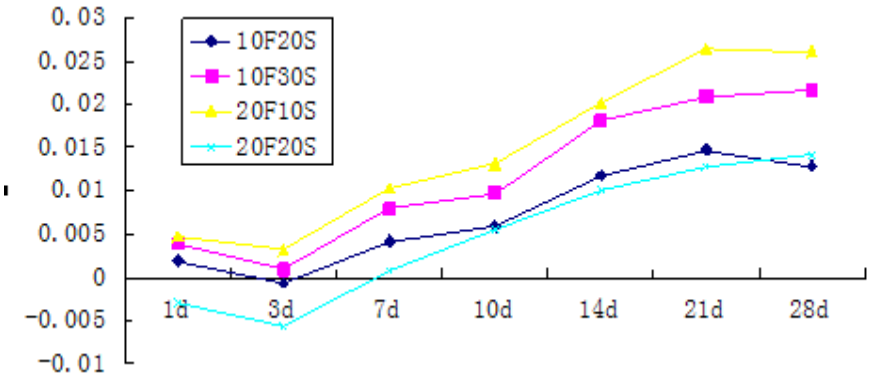

Fig 2 The expansion result add slag and fly ash

The figure above shows that both of the specimens' 14d expansions are less than0.3%,and 28d expansion are less that 0.1%. So no matter standard GB/T 50733-2011[8]or standard TB 10424-2010[10] be refered to, the inhibition is available.

What's more, the expansion rate is slower and slower with the increasing curing age. And the 21d expansions are almost equal to the 28d expansions, it indicates that the specimens' expansion is very slowly, and the suppress effect is very well.

Contrasting to the 1d expansion data and 3d expansion data, the specimens are getting shorter, the reason has 2 respects: the first one is that there have so many cracks in the mortar bars, and the gel produced by ASR can fill into them firstly, this phenomenon will not lead to expansion. The second one is that the cement gel will shrink after its hydration[13].

In the four combinations, the best one is 20% fly ash and 20% slag, and the worst one is 20% fly ash and 10%. But the expansion isn't always decrease with the increase of the dosage of slag. It means sometimes slag has opposite effect.

The reason is stated below.

Slag has large numbers of CaO, which can promote ASR. The low Ca calcium fly ash，has 2%~4% CaO, but the slag has 38%-46% CaO [14].And $Ca(OH)_2$ is harmful to the problem of ASR[15]. The amount of Na^+, K^+ in C-S-H is relate to its Ca/Si，the lower the Ca/Si is, the more the C-S-H absorbed[16].The more the slag is, the more the $Ca(OH)_2$ is, and the absorbing capacity is lower, and more Na^+, K^+ be released to the pores beside the aggregate, so the ASR is fiercer. When the expansion is large, slag's inhibit effect plays a major role, but when the expansion is small, slag's promote effect plays a major role.

To contrast the inhibit effect between fly ash and slag, Fig.1 and Fig.2 can be put together.Fig.3 shows the result.

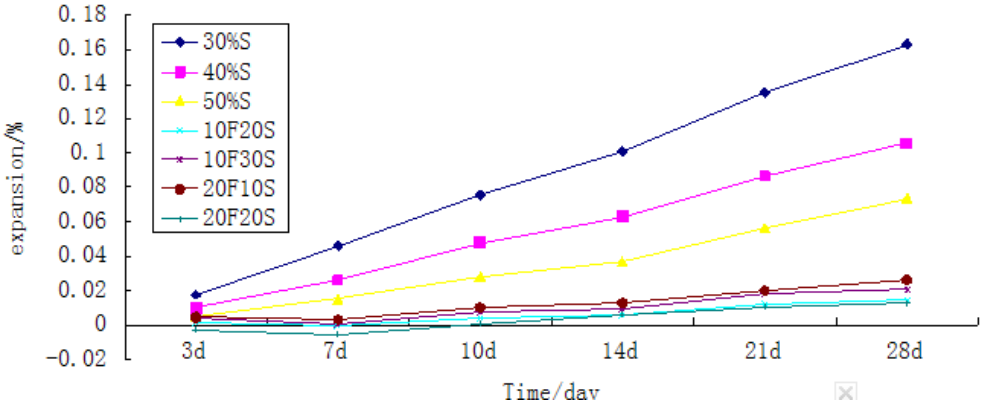

Fig 3 the expansion with slag and fly ash

From Fig.3 above, conclusion can be drawn that the fly ash's inhibit effect is much better than the slag's, even the fly ash's dosage is only 10%, the expansion decrease significantly. The conclusion is accord with former studies[17,18]

Mechanism

The mechanism of fly ash and slag inhibiting ASR are alike, as below shows.[19,20,21].
(1).The admixture can react with $Ca(OH)_2$,which is harmful.
(2).The admixture can fill into the pores around aggregates, and lead to the motar bar compact.
(3).The pozzolanic reaction products C-S-H gel which has low Ca/Si.
(4).The acidic particles in fly ash or slag can absorb K^+,Na^+, and lower PH value in pores.

Summary

(1).50% slag can inhibit ASR reluctantly with the aggregate of sandstone, and the inhibitory effect of fly ash is far better than slag.
(2)When the ASR is fierce, slag can inhibit ASR, otherwise slag can promote ASR.

Keywords: plastic concrete; clay dosage; proportion of mixture; strength, analysis of the influence

Abstract: This test is sand coarse aggregate ratio, ratio of water to cementitious material, cement dosage, bentonite dosage, type of sand and type of bentonite in certain cases, studied the influence of clay dosage and curing age on the basic mechanical properties of plastic concrete, it is concluded that the best clay dosage; the clay dosage has a great influence on all the strength of plastic concrete (compressive strength, splitting tensile strength, rupture strength), with the increase of clay dosage and all kinds of strength decreased; when clay dosage is certain, various strengths of plastic concrete are increased with the increase of curing age, curing age has a great influence on various strengths of plastic concrete. If the long curing age (540d) intensity values as the actual strength of plastic concrete, growth rate of strength of 540d long age relative to the 28d age about 120%, this shows that plastic concrete has a higher late strength, plastic concrete curing age longer than concrete curing age.

Introduction

Plastic concrete is a kind of flexible engineering composite materials that between ordinary concrete and clay, by using bentonite or clay replace partial cement in ordinary concrete to form, sometimes in order to improve the performance of plastic concrete, cement savings, reduce investment, but also mixed with fly ash and admixtures. According to the different composition of cementitious materials plastic concrete can be divided into three types of concrete: clay plastic concrete, bentonite plastic concrete, clay and bentonite plastic concrete [1].

Our country is an agricultural country and water is the lifeblood of agriculture. 2011 Central Document No. 1 emphasized the water conservancy as priority areas of national infrastructure construction, the irrigation as a key task in rural infrastructure and develop the people's livelihood and water conservancy, So water conservancy construction is the main focus of China's Twelfth Five-Year Period [2]. With the development of China's water conservancy and hydropower utilities, plastic concrete investment scale of several hundred billion yuan a year for water and soil conservation, harnessing of rivers, reservoirs reinforcement and dam seepage, large construction pit seepage and protection of ancient buildings and other underground seepage control project, and engineering of plastic concrete cutoff wall increased year by year. In the large water conservancy hub project (Three Gorges Project, The Yellow River Xiaolangdi Dam project , Ertan Hydropower Station and so on), cutoff wall technology of plastic concrete has been successfully applied and promotion. For water conservancy engineering and underground engineering have higher seepage control requirements, it very broad application prospects for using plastic concrete seepage instead of the past curtain grouting. With the continuous expansion of the plastic concrete engineering applications, in the practical application of the plastic concrete, clay amount more, will greatly reduce the strength of plastic concrete, and with less, the performance of plasticity concrete does not fully reflect, a large number of scientific issues about performance and applications plastic of concrete need to be studied and resolved as soon as possible; therefore, study of the influence of clay dosage and curing age on the strength of plastic concrete has important theoretical significance and application value.

Experiments

Experimental Design

The purpose of this test is in sand coarse aggregate ratio, ratio of water to cementitious material, cement dosage, bentonite dosage, type of sand and type of bentonite certain cases, studied the influence of clay dosage and curing age on the basic mechanical properties of plastic concrete, it is concluded that the best clay dosage; the results will provide research based for further enrich the theoretical of plastic concrete, formulate norms protocols of plastic concrete and promotion of engineering of plastic concrete.

Varying parameters of test are sand coarse aggregate ratio, ratio of water to cementitious material, cement dosage, clay dosage, bentonite dosage, type of sand, type of bentonite and curing age etc., as shown in Table 1.

TABLE 1 TEST PARAMETERS

Study on factors	Variation of parameters			
Sand coarse aggregate ratio	0.4	0.5	0.6	
Ratio of water to cementitious material	0.75	0.87	1	
Cement dosage(kg/m^3)	90	120	150	
Clay dosage(kg/m^3)	180	220	260	
Bentonite dosage(kg/m^3)	40	70	100	
Type of sand	Coarse sand, fineness module 3.3		Medium sand, fineness module 2.7	
Type of bentonite	Calcium bentonite		Sodium bentonite	
Curing age(d)	28	90	180	540

Experimental Raw Material

Cement

Test uses ordinary portland cement of 42.5 #, the indicators are in line with regulations of Common portland cement (GB175~2007) [3], detailed data see ref [2].

Clay and Bentonite

The silty clay that the test using from Longzihu Lake Zhengdong New District of Zhengzhou. After drying the sample, ground to a powder with standard of 350 mesh particle size. Test using calcium bentonite and sodium bentonite, the main physical and chemical indicators of calcium bentonite and sodium bentonite see ref [2].

Coarse Aggregate and Fine Aggregate

Coarse aggregate used in the test is gravel that particle size of 5 ~ 20mm. According to regulations of Specification of pebble and crushed stone for building (GB/T14685~2011) [4], the stone used for size distribution testing, particle gradation of 5 ~ 20mm gravel meets the requirements of the standard. Experiment uses two kinds of different thickness of sand. The sand used for particle screening, according to requirements of Sand for construction (GB/T14684~2011) [5] and Specifications for hydraulic concrete construction (DL/T5144~2001) [6], and results see ref [2].

Analysis of Test Results

When the ratio of water to cementitious material was 0.87 and the sand coarse aggregate ratio was 0.5, analysis of influence of different clay dosages and curing ages on compressive strength, splitting tensile strength and rupture strength of plastic concrete.

Influence of Clay Dosage and Curing Age on Compressive Strength of Plastic Concrete

To examine influence of clay dosage and curing age on compressive strength of plastic concrete, analysis of the relationship between increment of clay dosage and growth rate of compressive strength of plastic concrete, and the results are shown in Table 2. In the three kinds of clay dosage, the relations between the growth rate of compressive strength and curing age are shown in Table 3.

TABLE 2 RELATIONSHIP BETWEEN CHANGE OF CLAY DOSAGE AND GROWTH OF COMPRESSIVE STRENGTH OF PLASTIC CONCRETE

Change of clay dosage	Rate of change of clay dosage (%)	100mm growth rate of cubic compressive strength (%)		150mm growth rate of cubic compressive strength (%)	
		28d	90d	28d	90d
180~220	22.22	-16.01	-3.31	-8.08	-7.72
220~260	18.18	-34.53	-19.77	-27.47	-21.51

As can be seen from Table 2, the change on clay dosage have a bigger influence compressive strength of concrete, compressive strength of plastic concrete cube of curing age 28d and 90d are accelerated to reduce with increases of clay dosage, the greater the amount the more significant effect. Plastic concrete has the best clay dosage. In this experiment, when clay dosage in 180kg/m3 to 220kg/m3, the cubic compressive strength is reduced slightly, and when clay dosage is more than 220kg/m3, cubic compressive strength drastically reduced. Under the conditions of this experiment, the best clay dosage of one cubic metres of plastic concrete is 220kg.

TABLE 3 RELATIONSHIP BETWEEN CLAY DOSAGE AND COMPRESSIVE STRENGTH GROWTH RATE OF PLASTIC CONCRETE

Clay dosage (kg)	100mm cubic compressive strength (MPa)			150mm cubic compressive strength (MPa)		
	28d	90d	Growth rate of strength	28d	540d	Growth rate of strength
180	2.31	2.72	17.7%	1.98	4.4	122.22%
220	1.94	2.63	35.6%	1.82	4.0	119.78%
260	1.27	2.11	66.1%	1.32	2.9	119.70%

It is seen from Table 3, curing age has great influence on the compressive strength of plastic concrete cube, 90d age relative to the 28d age growth rate of strength with increasing clay dosage increased, growth rate of strength of 540d long age relative to the 28d age about 120%. With the increase of the clay dosage, growth rate of compressive strength of plastic concrete cube caused by curing age acceleration increases, indicating that the more the clay dosage the slower growth of plastic concrete strength, the higher strength relative to the late 28d age.

Influence of Clay Dosage and Curing Age on Splitting Tensile Strength of Plastic Concrete Cube

Changes in the clay dosage, the growth rate results of curing age changes and plastic concrete splitting tensile strength are show in Table 4.

TABLE 4 RELATIONSHIP BETWEEN CLAY DOSAGE AND SPLITTING TENSILE STRENGTH GROWTH RATE OF PLASTIC CONCRETE

Clay dosage(kg)	100mm cubic splitting tensile strength (MPa)			150mm cubic splitting tensile strength (MPa)		
	28d	90d	Growth rate (%)	28d	90d	Growth rate (%)
180	0.35	0.40	14.3%	0.27	0.38	40.7%
220	0.32	0.36	12.5%	0.24	0.35	45.8%
260	0.23	0.33	43.5%	0.18	0.29	61.1%

It is seen from Table 4, the effect of curing age on splitting tensile strength of plastic concrete is larger, growth rate of plastic concrete splitting tensile strength of 90d curing age relative to the 28d age above 10%, the highest reached 61.1%. With the increase of the clay dosage, growth rate of splitting tensile strength of plastic concrete cube increased with curing age increases, which indicates that the more the clay dosage, the longer its curing age. Meanwhile, the effects of curing age on splitting tensile strength of plastic concrete 150mm cube is much larger than splitting tensile strength of 100mm cube, which may be the role of the size effect.

Influence of Clay Dosage and Curing Age on Rupture Strength of Plastic Concrete

Growth rates of rupture strength and difference of rupture strength between the different of clay dosage plasticity concrete are show in Table 5.

TABLE 5 RELATIONSHIP BETWEEN CLAY DOSAGE AND RUPTURE STRENGTH GROWTH RATE OF PLASTIC CONCRETE

Curing age	Clay dosage 180~220 difference of rupture strength (MPa)	Growth rate of strength (%)	Clay dosage 220~260 difference of rupture strength (MPa)	Growth rate of strength (%)
28d	-0.15	-20.0%	-0.09	-15.0%
90d	-0.08	-10.7%	-0.06	-9.0%

It can be seen from table 5, with the increase of clay dosage, rupture strength of 28d curing age plastic concrete decreased, the rupture strength decrease above 15%; rupture strength of 90d curing age plastic concrete decreased also, the rupture strength decrease about 10%, below the decrease of flexural strength of 28d age.

Conclusion

This test is in sand coarse aggregate ratio, ratio of water to cementitious material, cement dosage, bentonite dosage, type of sand and type of bentonite certain cases, studied the influence of clay dosage and curing age on the basic mechanical properties of plastic concrete, the main conclusions are as follows:

(1) The clay dosage has a great influence on all the strength of plastic concrete (compressive strength, splitting tensile strength, rupture strength), with the increase of clay dosage and the all kinds of strength of decrease.

(2) When clay dosage is certain, various strength of plastic concrete are increased with the increase of curing age, curing age has a great influence on various strength of plastic concrete. If the long curing age (540d) intensity values as the actual strength of plastic concrete, the compressive strength of plastic concrete on 90d reached only about 65% of the actual strength [7], this shows that plastic concrete has a higher late strength, plastic concrete curing age longer than the concrete curing age.

(3) Changes of clay dosage have a great impact on compressive strength of plastic concrete cube, compressive strength of plastic concrete cube of curing age 28d and 90d are accelerated to reduce with increases of clay dosage, the greater the amount the more significant effect. Plastic concrete has the best clay dosage. Under the conditions of this experiment, the best clay dosage of one cubic metres of plastic concrete is 220kg.

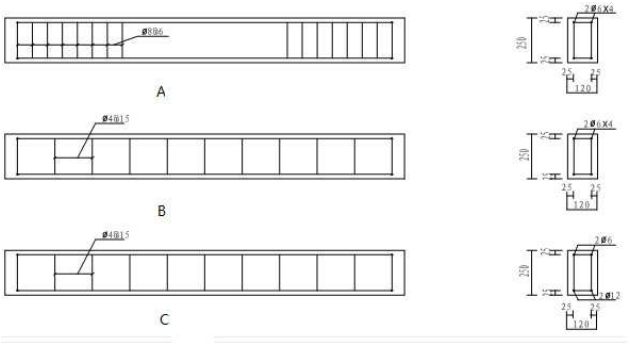
Keywords： Reinforcement Technology, Concrete structure, Bearing capacity

Abstract: Three reinforcement materials with steel plate, epoxies resin sheet, and glass fiber sheet adhering to failed reinforced concrete beams (RC beams) were used to improve the bearing capacity of Reinforced Concrete beams in the paper. The test results shows all the three materials were proved satisfied with bearing capacity increasing request. Strengthening effects with steel plate and epoxies resin sheet were more obvious.

Introduction

At present, the reinforced concrete structure is widely applied in civil engineering in the world. The structural functions will gradually decline in the influence of erosion, natural environment condition, even unable to satisfy the requirements of normal use[1,2,3]. Therefore, we must take some measures to reinforce the structure, otherwise , the structure will be prematurely terminated. The mature reinforcement methods used today are structure member strengthenting with R.C , structure member strengthenting with R.C ,structure member strengthening with externally bonded reinforced materials,compression member confined by reinforcing wire,structure member strengthening with externally applied prestressing,etc.[4,5,6].Three reinforcement materials with steel plate, epoxies resin sheet, and glass fiber sheet adhering to failed RC beams were compared by experiments in this paper.



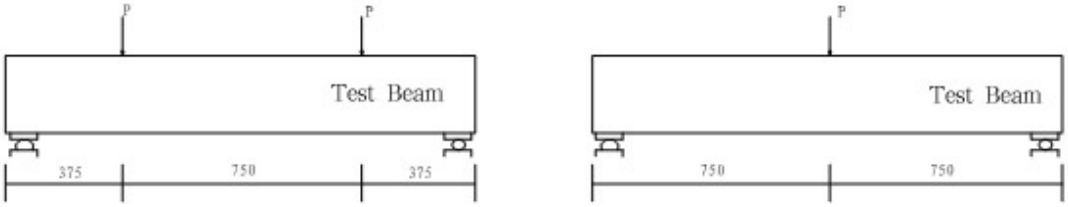


Fig.1 The Different Reinforcement Drawing of Test Beams

Brief Introduction of Test

The size of the test beams is 1500mm × 250mm × 120mm, the concrete grade is C25, with three kinds of reinforcement marked A, B and C .The reinforcement drawing is shown in Fig.1. In order to accelerate the steel corrosion, the main bar is connected to external wire before concreting.

The test is designed like this: the RC beams prepared will be damaged by loading. Loading system is shown in Fig.2. There are two types of loading system: double concentrated forces and single concentrated force. The loading point of the symmetrical loading mode from each end is

375mm, single concentrated force directly loaded at mid-span. The load is applied step by step through hydraulic jack and force transmitting frame.

a double concentrated forces b single concentrated force

Fig.2 The Schematic Diagram of Loading System

Reinforcement treatments are conducted on the failed reinforced concrete beams by adhering steel plate, epoxies resin sheet and multilayer glass fiber sheet respectively. Through experimental comparison, the optimum scheme will be selected.

Reinforcement Materials and Scheme

The type of reinforcement plate is Q235, 3mm thickness, the bottom area of the reinforcement beam increases 3.0cm2; the thickness of epoxies resin sheet is 5mm, 4 cloth 5 glue boards; the width of glass fiber sheet is 50cm. Adhesive glue used is epoxy structural adhesive .The reinforcement scheme of various materials is shown in Tab. 1.

C2	61.6	76.9	S	17.8	35.5
C3	63.0	71.5	S	17.8	46.6
C4	60.6	85	S	26.6	46.6
C5	58.7	65	S	17.8	35.5

Note: D-double concentrated forces

S-single concentrated force

In the process of test, when the load increases to a certain extent, the original cracks of the beam will expand again, or new cracks emergence .The load value is greater than the cracking load before reinforcement (shown in Tab. 3).

TAB.3 STATISTICAL TABLES OF LOAD CAPACITY IMPROVEMENT

	category	A（double concentrated forces）	B（single concentrated force）	C（single concentrated force）
Glass Fiber sheet	Steel plate	More than 7.79	32.76 More than 24.27	
	Epoxies resin sheet	7.37	44.09 40.37 5.99	24.84 40.26
	Bottom 2 layer Side 1 layer	6.77 7.01		10.73
	Bottom 3 layer		2.47	
	Bottom 3 layer Side 2 layer		18.31 3.75	
	Bottom 3 layer Side 3 layer		12.82	
	Bottom 4 layer		12.39 14.43	

Bottom 4 layer Side 1 layer		13.49
Bottom 4 layer Side 2 layer	17.79	
Bottom 4 layer Side 3 layer	6.62	

The beams labeled A4,B5 and B9 don't be reinforced because of serious damage. The bearing capacity of the beams after reinforcement increase by 2.47 ~ 44.09%. The increase rate under double concentrated force is inefficiency, less than 10%. Under the same loading mode (single concentrated force or double concentrated force)under the same conditions, the reinforcement effect of using steel plate or epoxy resin board is better than that of the glass fiber steel. The contribution to improve the bearing capacity of using steel plate or epoxy resin board is basic equivalent.

Conclusion

(1)Overall,various reinforcement material used basically meet the requirements of strengthening the bearing capacity, bearing capacity after strengthening are improved to different degrees, but the use of steel plate and epoxies resin sheet increase more.

(2)Scheme selection in practical engineering should be based on different components and site situation. In principle, epoxies resin sheet and glass fiber sheet can be considered while security is guaranteed. Especially in the narrow operation space, the first choice is glass cloth as reinforcement material.

(3)In general, all three kinds of reinforcement material above can meet the requirements of the bearing capacity, but the durability remains to be study further ,especially the anti-corrosion of the steel plate. Besides, the age resistance of the epoxies resin sheet, glass fiber sheet and binder is worth further study.

Mechanical properties of crumb rubber concrete

Jun Cai

Department of Urban and Rural Development & Management Engineering, Shangluo University, Shangluo, China

deyi2665@126.com

Keywords: crumb rubber concrete, mechanical property, flexural toughness

Abstract: Crumb rubber concrete (CRC) has been widely used in many countries because of its good performance. This paper presents the results of a study on mechanical properties of crumb rubber concrete (CRC). The compressive strength, splitting tensile strength and flexural toughness of CRC were investigated. The effect of crumb rubber proportion on the mechanical properties was experimentally analyzed. The test results indicate that the addition of crumb rubber can significantly improve the ductility and flexural toughness of CRC.

Introduction

Crumb rubber concrete (CRC) is known as a promising material because of its better performance and the utilization of crumb rubber from discarded scrap tyres. The properties of fresh and hardened CRC were investigated in previous papers. CRC showed lower density, better sound insulation and acoustic absorption compared with conventional concrete[1-4]. In this paper, the mechanical properties of CRC were experimentally studied. The effect of crumb rubber proportion on the mechanical properties (compressive strength, splitting tensile strength and flexural toughness) of CRC was experimentally investigated.

Experimental program

Materials and mixture proportions

Ordinary Portland cement was used in this study. The coarse aggregate was crushed stone with diameter of 5-20 mm. The fine aggregate was natural sand with a maximum size of 5 mm. Fly ash was used as mineral addition. A polycarboxylic superplasticizer was used in all concrete mixtures. Crumb rubber content used was 25 kg/m^3, 50 kg/m^3 and 75 kg/m^3. The details of the mixture proportions are shown in Table 1.

TABLE 1. MIXTURE PROPORTIONS OF CONCRETE.

Mixture	Rubber (kg/m^3)	Cement (kg/m^3)	Water (kg/m^3)	Coarse aggregate (kg/m^3)	Fine aggregate (kg/m^3)	Fly ash (kg/m^3)	Superplasticizer (kg/m^3)
C	-	375	160	980	420	160	32
CRC 25	25	375	160	980	420	160	32
CRC 50	50	375	160	980	420	160	32
CRC 75	75	375	160	980	420	160	32

Test procedure

Cubes (100 × 100 × 100 mm) were used to evaluate the compressive strength and splitting tensile strength in accordance with Chinese Standard GB/T 50081-2002.

The four-point loading flexural tests were carried out on the beams (100 × 100 × 400 mm) with a closed-loop arrangement in accordance with ASTM C1018. The loading was displacement control at a rate of 0.05 mm/min. Both the applied load and the specimen midspan deflection were recorded

throughout the test. The flexural toughness of all the mixtures were evaluated by measuring the load-deflection curves in accordance with JSCE SF-4 standard [5].

In accordance with the JSCE method, the flexural toughness factor (σ_b) is defined as:

$$\sigma_b = \frac{\tau_b}{\delta_{tb}} \times \left(\frac{l}{b \times h^2} \right) \quad (1)$$

Where l is beam span (300 mm in this study), b is beam width (100 mm in this study), h is beam depth (100 mm in this study), $\delta_{tb} = l/150$ (2 mm in this study), τ_b is the area under the load-deflection curve up to a midspan deflection of δ_{tb}.

Results and discussion

Compressive strength and Splitting tensile strength

The compressive strength and splitting tensile strength values of all the mixtures are illustrated in Fig. 1and Fig. 2, respectively. The test results show that compressive strength and splitting tensile strength decreased with the increase of crumb rubber content. The decrease in compressive strength and splitting tensile strength is due to the increase of porosity caused by the incorporation of crumb rubber.

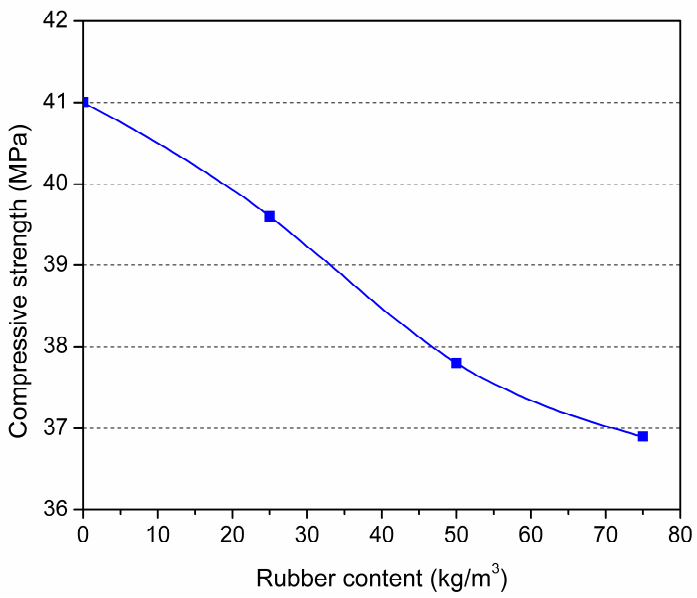

Fig. 1. Effect of rubber content on compressive strength.

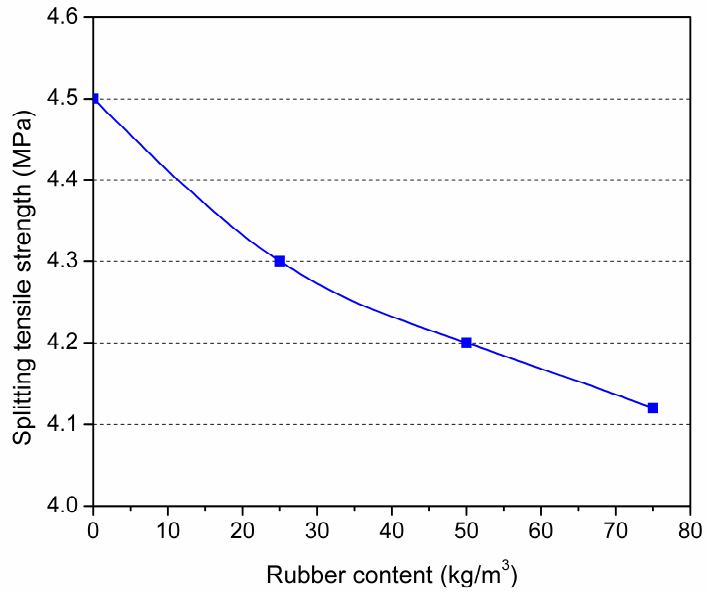

Fig. 2. Effect of rubber content on splitting tensile strength.

Flexural toughness

The flexural load-deflection curve of CRC is shown in Fig. 3. It can be observed that the crumb rubber has great effect on the flexural properties of CRC. The beams show better post-peak behaviour with the increase of crumb rubber content. The load-carrying capacity of CRC improve significantly.

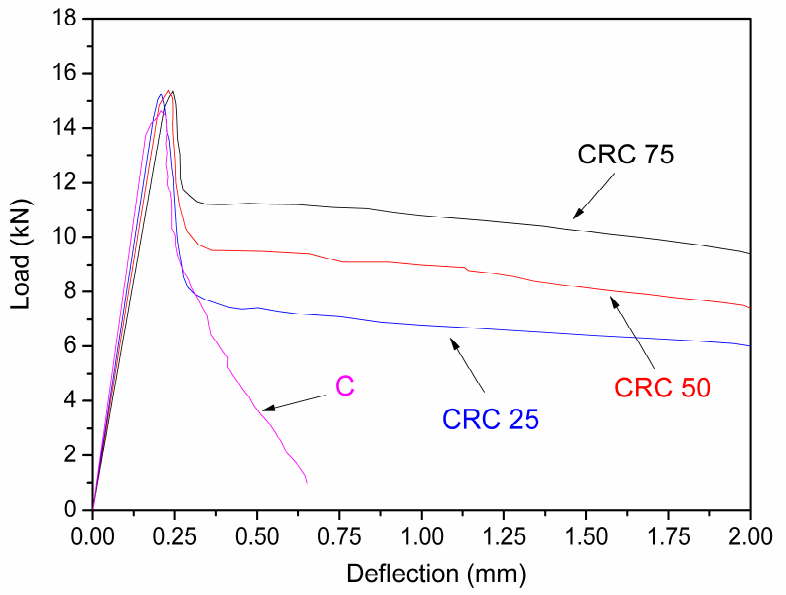

Fig. 3. Flexural load-deflection curve of CRC.

The flexural toughness factor of CRC at various rubber contents is shown in Fig. 4. The results indicate that flexural toughness factor increased with the increase of rubber content. Crumb rubber content has significant effect on the flexural properties of CRC. The flexural toughness improvement of CRC enhanced with the addition of crumb rubber.

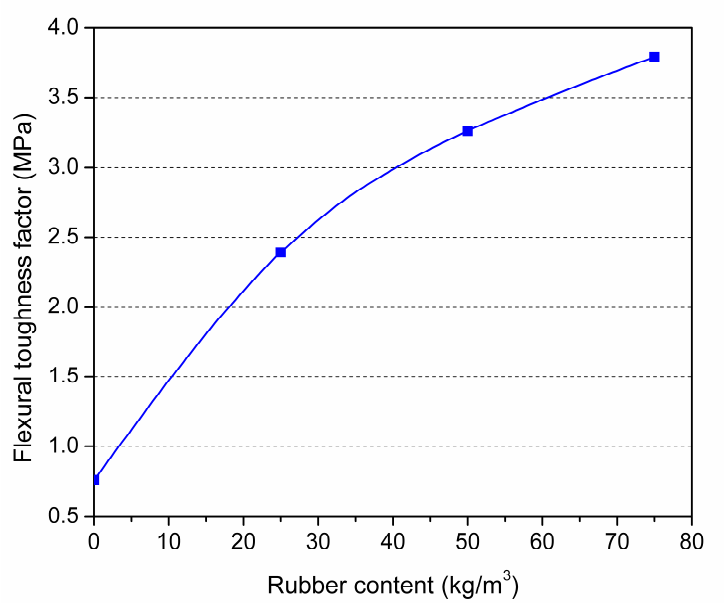

Fig. 4. Effect of rubber content on flexural toughness factor.

Conclusions

This paper studies the effect of crumb rubber on the mechanical properties of CRC. Compared to control concrete without crumb rubber, compressive strength and splitting tensile strength of CRC decreased with the increase of rubber content. The crumb rubber has significant effect on the flexural properties of CRC. The flexural toughness factor of CRC increased with the increase of rubber content. The ductility and flexural toughness of CRC were significantly improved by the addition of crumb rubber.

Keywords: Cement stabilized gravel; rubber particles; dry shrinkage performance

Abstract: Cement stabilized gravel has good characters like high strength, good stability, anti-erosion properties and better anti-fatigue property, but it is easy to produce desiccation cracks when humidity changes (caused by evaporation), resulting in reflection crack on the bituminous pavement surface, and then influences performance and the service life of the pavement. Along with the changes in traffic conditions, semi-rigid asphalt concrete pavement meets the two major challenges as early damage and heavy traffic. It has significant economic and social significance that support a method of construction and conserve of semi-rigid pavement which accommodate heavy traffic highway and has guidance and reference value in other conditions. It is analyzed by comparison between the performances of mixture with best amount of admixture which obtained by shrinkage test and mixture without admixture.

Introduction

Semi-rigid type base is base that paved by inorganic binder stabilized soil can form a plate and have certain flexural strength. It is helpful to improve the carrying capacity of the road that about 95% of high-grade asphalt concrete pavement base or subbase are semi-rigid material with increasing strength, considered highway pavement which has been built in China.[1,2] However, it is widespread that shrinkage cracking of semi-rigid base and reflective crack of asphalt pavement exist. It is generally taken for cracks sealing but it is difficult on highway or heavy traffic road.

Cement stabilized crushed stone is a semi-rigid pavement structure type emerging in recent years for highway subbase, base construction. It is gradually favoring the design and construct department because of good plate body, water stability, frost resistance, adjustable mechanical strength and good carrying capacity as the bearing layer of asphalt concrete. It is hard to control the material grading, cement dose, paving compaction, segregation treatment, survival time and maintenance so that even the slightest mistake will cause the defect as cracks or thickness, strength that does not meet the design requirements, causing immeasurable losses which the construction companies always spoke of with horror.

Use of waste rubber has far-reaching practical significance. Recycling and treatment technology of scrap tires, called 'black' pollution, is a worldwide problem. The most common practice is to bury or dump waste tires. It not only cause a lot of land expropriation, but the accumulation of a large number of waste tires can easily cause a fire, causing second pollution.[3]

Design of aggregate particles consisting

Coarse aggregate in the mixture of cement stabilized crushed stone play the skeleton role mainly while fine aggregate play the filling role. Aggregate particles directly affect the mechanical properties of the mixture. Reasonable mix of coarse and fine aggregates can make the base more dense, better overall performance and higher compressive strength. To achieve higher density and larger friction, various size aggregates are matched up according to a certain proportion. There are two graded and

this study uses a continuous gradation.[4,5]Synthetic aggregate gradation(Particles) is shown in Table 1 and Fig. 1.

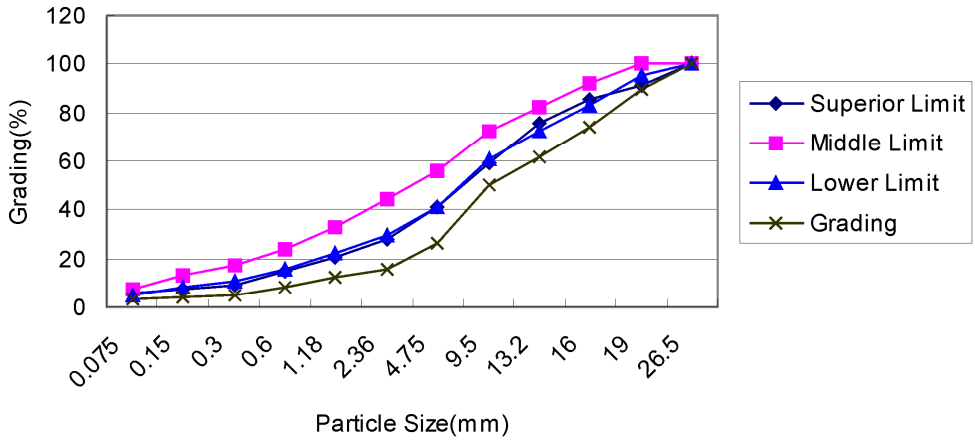

Fig. 1 Grading design of all natural aggregates AC-20 mineral aggregate

Rubber cement stabilized macadam base contraction performance test

Drying shrinkage mechanism

Volume reduction caused by water evaporation, hydration, temperature decreases and other factors in the base of stable inorganic binder material is called shrink of stable inorganic binder material base. Large elastic stress caused by base shrinkage deformation climb with the increase of elastic modulus and shrinkage of base. Creep caused by contraction can reduce such stress to some extent, but if the tensile stress growth after creep relaxation exceeds the tensile strength of the base, it will cause cracking base and seriously affect the performance of the road after reflecting the pavement surface.

Water mixture will continue to decrease after the stable inorganic binder material mixed and compacted because of the internal hydration and water evaporation. Capillary action , adsorption , the role of intermolecular forces , the role of water and Carbonation contraction of mineral crystal material between layers or gel will cause volume shrinkage of stable inorganic binder material. This phenomenon is called drying shrinkage.

Production and conservation of specimens

Hydrostatic press molding method was used to product beam specimens of 100mm×100mm×515mm. Those 24 specimens are divided into 8 groups, and ingredient content of specimens in each group are shown in Table 2.

Produced specimens are placed in 20±2ºC RH90% conditions and are placed vertically above the shrinkage instrument to dry naturally after it has been removed after 7 days conserve.

Results and analysis of shrinkage test

Shrinkage strain variation with time

Fig.2 and Fig.3 are made to analyze by taking the same time interval (1day) and excluding the test data of last day.

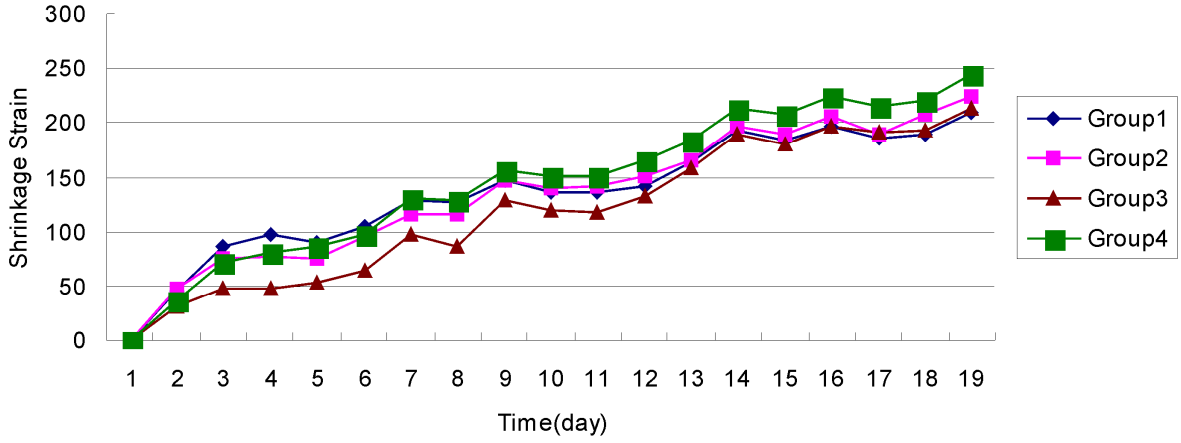

Fig.2(60 mesh) Relationship between shrinkage strain and the time

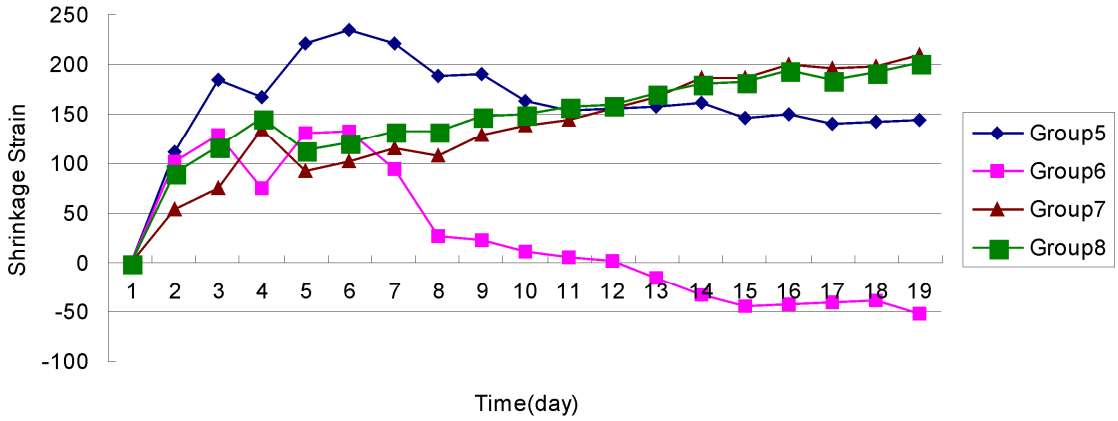

Fig.3 (80 mesh) Relationship between shrinkage strain and the time

As it can be seen from Figures 3 and 4, along with the time, shrinkage strain are gradually climbing (except group 6)and easing in the end. In Fig.3 Shrinkage strain of all-natural solutions essentially maintain a higher level in shrinkage strain than others, but taking a panoramic view of the situation, group 3 has the best improvement of shrinkage performance while the all natural group is the worst.

When mixed with 80 mesh rubber powder, shrinkage strain of cement stabilized gravel changes larger in the first two days and it is significantly easing from the third day and shrinkage strain changes little in the end. Group 6 manifest strange characteristic that is the same with other groups during the first 6 days, but swelling phenomenon whose reason is unknown because that all groups are set in the same cultivating conditions occurred since the 6th day. So this program is invalid. Excluded group 6, from the performance of the other three groups, group 7 is the best while the all natural group is the worst.

In order to optimize when the same dosage (0.25%) of rubber powder (60 mesh or 80 mesh), group 3&7 are compared individually the result is shown as Fig.4.

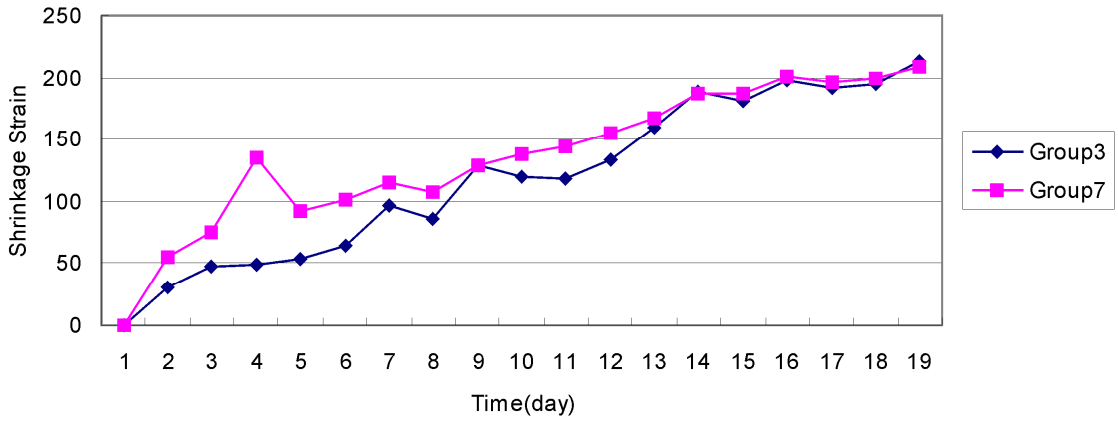

Fig.4 Shrinkage strain contrast of group 3&7

It is easy to find by contrast, shrinkage strain of group 3 is smaller so 60 mesh rubber powder 0.25%replace0.15 is selected to make the greatest improvement in shrinkage performance of cement stabilized crushed stone.

All-natural cement stabilized mixture specimens (group 4&8) basically maintained a high growth trend compared to other groups while incorporation of rubber particles slow down the growth of shrinkage strain from growth trend. The reason might be that cement hydration reaction occurs first by adsorbing water from the surrounding because of the good absorption capacity of rubber particles and then capture previously absorbed moisture of rubber particles to recover a part of their shrinkage. On the other hand, to a certain extent, due to the larger flexibility abate capillary tension caused by water evaporation, the role of intermolecular forces and the role of adsorbed water. Thereby the shrinkage is reduced.

Although the shrinkage characteristics of cement stabilized macadam improved after mixed with rubber powder, but it's not very obvious especially in the latter of observation. We can make nothing of that shrinkage strain versus time curve will remain stable or the difference will expand because of various aspects condition.

Water loss rate variation with time

Similarly, we take the same time interval (1day) and exclude the test data of the last day. Figure 5 is made for analysis.

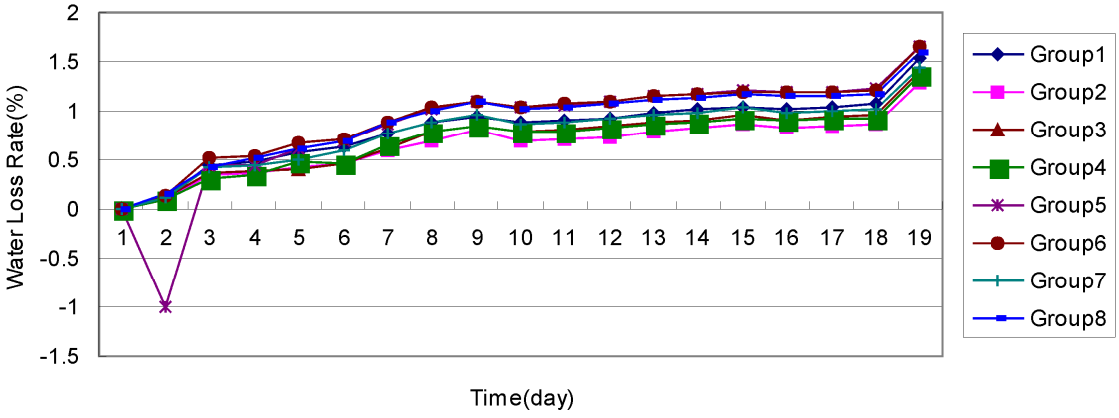

Fig.5 Water loss rate changes with time

It is shown in Fig.5 that specimen loss rate increases with the increase of time. Dehydration is rapid early and it star slowing down from the 8th day which point out the essentiality of the 7th day after cement stabilized macadam compaction ended.

Water loss rate of each group stabilized at about 9th day include that the dehydration is basically the same period after incorporation of rubber powder.

Conclusion

After mixed with a certain amount of rubber particles, shrinkage strain decreases. Shrinkage strain of specimen incorporated within rubber particles is slackening in growth. We should choose 60 mesh rubber powder 0.25% replace0.15 to make the prominent improvement of shrinkage strain of Cement stabilized crushed stone.

Water loss rate rise with increasing time and eventually stabilized and there is no significant relationship between water boss rate and the type or dosage of rubber powder.

Keywords: Bending properties, Laser welded, Web-core steel sandwich plate, Weld width

Abstract：This paper presents a detailed discussion of the bending properties of laser welded web-core steel sandwich plates and the influence of weld width on stiffness and strength. The over-hanging three point bending test was conducted on the laser welded web-core steel sandwich plates with various welds width by self-designed device, together with the finite element simulations. A good agreement is obtained between the 2D FE analyses and experiment results. The stiffness and strength of the sandwich plates increased with the increasing of weld width, especially for the weld width lower than 60% thickness of the core plate. It is necessary to consider the weld width in the design and evaluation of the stiffness and strength of the laser welded web-core sandwich plate. Base on the results, the FEM is the priority to analysis bending properties of laser welded web-core steel sandwich plates.

Introduction

All steel sandwich plates were found to be 30-50% lighter than traditional stiffened plates due to the thin face plates located away from the neutral axis [1]. Applications of steel sandwich plates in marine structures range from decks, bulkheads, antenna platform to hoistable ramps. Contemporary interest in steel sandwich plates has been awakened by the developments in laser welding technology which enables the efficient production of these plates. Elevated pre-fabrication accuracy of the components, high welding speed and the possibility to connect internal stiffeners with the face sheets from outside has led to a wide application of laser welding in the construction of steel sandwich plates [2].

Web-core steel sandwich plate has the simplest core structure, as showed in Fig.1. This plate has been under active investigations during the last 15 years. Romanoff studied the bending response of web-core sandwich plate using analytical and FEM methods, and the analytical formulations for stiffness and strength of web-core sandwich were exposed [3]. A lot work of the buckling strength of laser welded web-core sandwich plate has been done through the analytical method, finite element method and experiment, as reported in Ref. [4-6]. In these studies, the bending response is evaluated by transforming an originally discrete structure into an equivalent homogenous continuum giving a sandwich plate, and the T-joints of web-core sandwich plate was assumed as continuous features. Actually, the T-joint has a discontinuous features, i.e., there are root gap and inevitable weld offset, weld width is less than the thickness of the face or core plate, as be shown in Fig.1. Besides, the weld width was changes with the different welding parameters and the thickness

of face plates. Ref. [7] reported the ultimate strength of corroded web-core steel sandwich beams both by the experiments and the finite element simulation research, and the weld width may reduce the strength of the plates.

This paper presents a series of bending properties tests on web-core steel sandwich plates in over –hanging three point bending. In order to support and extend the experimental investigation, finite element simulations were performed to analyze the effect of weld width on stiffness and strength of the sandwich plate. Additionally, the bending and shear stiffness and bending strength of sandwich plate obtained by analytical formulation were compared with experimental and FEM results, to ensure the weld width has an important role in the design and evaluation of the stiffness and strength of the laser welded web-core sandwich plate.

Experimental and finite element simulation

The Dimensions of laser welded web-core steel sandwich plate and details of T-joint

The web-core sandwich plate consists of web and face plates, which are connected by laser weld, as be shown in Fig. 1. Two kinds of welding speeds were designed to achieve various laser welds dimensions. The welding parameters and weld width are listed in Table 1. The base metal used in this paper is high strength steel SPFH780. Tensile tests were conducted to determine the material properties. Yield strength of the base material is 631MPa.The tensile strength is 730MPa.

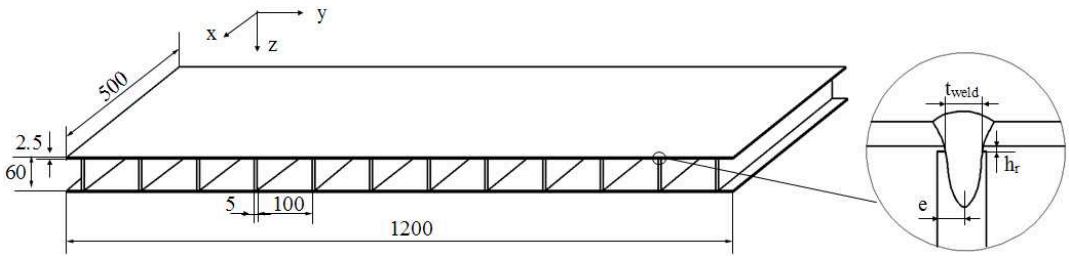

Fig. 1 Dimension of laser welded steel sandwich plate and details of T-joint

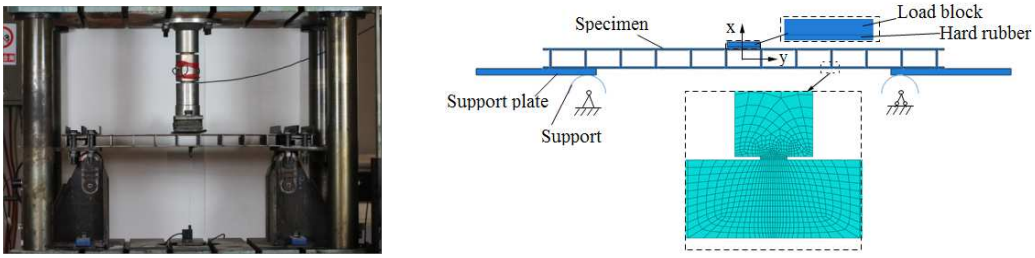

TABLE 1 THE WELDING PARAMETERS AND THE WELD WIDTH OF T-JOINT

Specimen number	1#	2#	3#	4#
V/(mm/min)	1200	1200	800	800

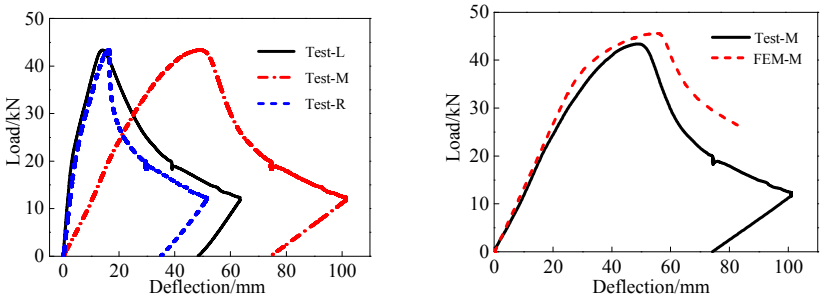
Three point bending test and finite element modeling

According to ASTM C393-00 standard test method for flexural properties of sandwich structures and GB/T 1456-2005 Performance test methods for sandwich structures, a special test setup which is suitable for simply support, as be shown in Fig. 2(a), was developed to measure the bending properties of sandwich plates by over-hanging three point bending test. The experiments were carried on a 3150kN column hydraulic machine. The span is 936mm, and loading speed is 5mm/min. The load and deflection were recorded by the load and displacement sensor.

The Abaqus6.11 standard solver was employed to analyze bending response of sandwich plates with various weld width, the weld width is varied between 1mm, 2mm, 3mm, 4mm and 5mm, and the root gap is 0.1mm for all models. Fig. 2(b) shows one of the 2D models. In the modeling of sandwich plate, the welds are all at the middle of each core plate. The elements used are CPE8R. In general the aspect ratio in rectangular elements is kept close to 1:2 and the angle in quadrangular between 45°-135° to avoid problems in accuracy of solution.



(a) The test setup of three point bending (b) FEM model

Fig. 2 The test setup of three point bending and FEM model

Result and discussion

The deformation of sandwich plate

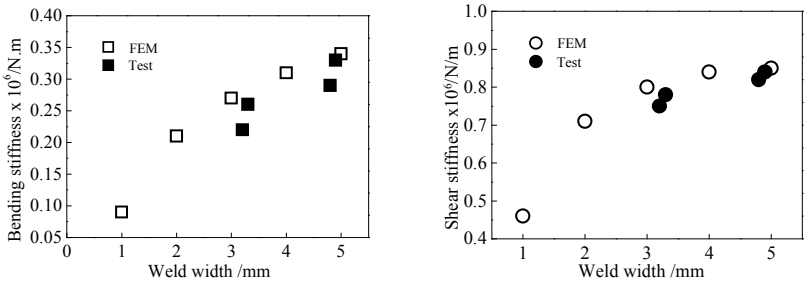
Fig. 3 displays the typical load-deflection curves. The middle span load-deflection curve was denoted Test-M, and the left and right over-hanging load-deflection curves were denoted Test-L and Test-R, respectively. As can be seen from Fig. 3(a), when the load is larger than 18 kN, the relationship load and deflection are not be linear, and then the larger load, the more gentle the curve. Additionally, Test-L and Test-R curves separated after the load over 18kN. When the load reached the maximum 43kN, the load- deflection curves start to fall. In Fig. 3(b), the FEM load-deflection curve is almost agree with the results in test, especially in the linear segment which will be selected to calculate the bending and shear stiffness. And the strength will be obtained by the max load.

(a) Load-deflection curves from testing (b) FEM result compares with the test curve

Fig.3 Load-deflection curves

The relationship between weld width and stiffness

Bending stiffness and shear stiffness are two important elastic parameters. They were calculated from the elastic segment of the load-deflection curve. The formula is as follows:



$$D_y = \frac{\Delta P \cdot l^3}{48 \cdot B \cdot \omega_b} \tag{1}$$

$$D_{Qy} = \frac{\Delta P \cdot l}{4 \cdot B \cdot (\omega - \omega_b)} \tag{2}$$

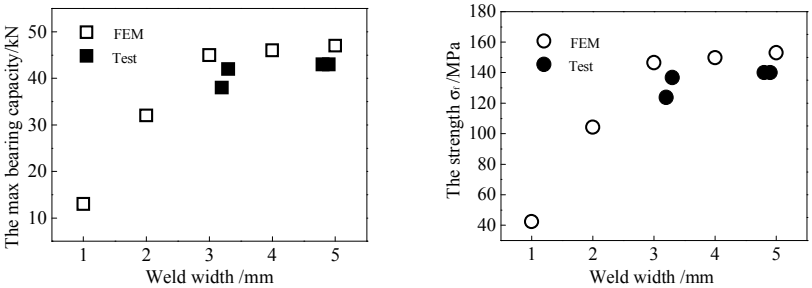
*where D_y is bending stiffness, in N.m; D_{Qy} is shear stiffness, N/m; ΔP is load increment, in N; l is span, in m; B is the width of specimen, in m; ω is the increment of mid span deflection corresponding increment of load, which is caused by the shear deformation of sandwich plate, in m; ω_b is the increment of lest or right over-hanging deflection corresponding increment of load is the deflection caused by the bending deformation, in m; which is caused by the shear deformation of sandwich plate, and $\omega_s = \omega - \omega_b$, in m.

Fig. 4 indicates the relationship between weld width and bending and shear stiffness of web-core sandwich plate. It can be seen that the larger weld width, the greater bending rigidity, as was shown in Fig. 4(a). As the weld width increases from 1mm to 2mm, the bending stiffness increased

0.12×10^6 N.m, while increased 0.03×10^6 N.m as the weld width increases from 4mm to 5mm. Similarly, shear stiffness increases obviously as the weld width lower 3mm (60% thickness of the core plate), see Fig. 4(b). Apparently, the weld width has a great impact on the stiffness of the sandwich plate, especially for the weld width is far less than the thickness of the core plate. However, there exist several publications related to the bending and transverse shear stiffness formulations for web-core sandwich plates all did not consider the weld width (Lok & Cheng, 2000, Kujala & Klanac, 2002, Kolaters, 2002) [8-10], this can lead to overestimates of the stiffness. Therefore, it should be to consider the influence of weld width on the stiffness in the process of design and optimization of laser welded web-core sandwich plate. As a result, the finite element method is the best choice for the stiffness analysis of the laser welded web-core sandwich plates.

(a) Weld width-bending stiffness (b) Weld width-shear stiffness

Fig. 4 The relationship between weld width and stiffness



The relationship between weld width and strength

Strength of sandwich plate is another measure of performance parameters. The strength of face plates was calculated from the maximum load, the formulation is

$$\sigma_f = \frac{P_{\max} \cdot l}{4 \cdot B \cdot t_f \cdot \left(h - t_f\right)^2} \tag{3}$$

*where σ_f is the strength face plates, in MPa; $P_{\max}$ is the maximum load, in N; l is the span, in m; t_f is the thickness of face plate; B is the width of specimen, in m; h is the height of specimen, in m.

Fig. 5(a) indicates the relationship between weld width and the max bearing capacity of web-core sandwich plate. In Fig. 5(a), it can be seen that with the increase of weld width, the max bearing capacity and the bending strength are increased. And when the weld width is greater than 3mm (60% thickness of the core plate), the bending strength can break the restriction of weld width. According to the formula (3), the strength of the face plate can be obtained, see Fig. 5(b). As the weld width increases from 1mm to 5mm, the max strength is lower 160MPa, which is far less than the yield strength of the face plate. It is recognized that a big error will occur in the strength design of the sandwich plate by the analytical techniques. Hence, the finite element analysis is a relatively better way to solve problems.

(a) Weld width-the max bearing capacity (b) Weld width-the face strength

Fig. 5 The relationship between weld width and strength

Conclusion

Base on the investigation into the bending properties of laser welded web-core sandwich plates. The following conclusions can be drawn:

(1) With the increasing of weld width, the bending and shear stiffness is increased, especially when the weld width is less than 3mm (60% thickness of core plate), this effect is more significant. In other words, weld width is greater than 3mm at least in the stiffness design for this kind of sandwich plates.

(2) It is quite clear that the maximum load capacity is increased with the increasing of weld width. When the weld width is greater than 3mm (60% thickness of the core plate), and then the bending strength can break the restriction of weld width.

(3) It is necessary to consider the effect of weld width on bending properties in the stiffness and strength design of laser welded web-core sandwich plate. The finite element method is an excellent choice for the stiffness and strength analysis of the laser welded web-core sandwich plates.

Keywords: Pseudo ductile cementitious composites Fiber concrete Ductility Rubber particles Tensile properties Compressive strength Water permeability Shrinkage

Abstract: Pseudo-ductile cementitious composites (PDCC) are a new type of special discontinuous random-fibers reinforced cementitious composites with high tensile ductility achieved by the uniform formation of multiple cracks along the length of the specimen. In the present study, rubber particle was introduced into the cementitious composites as the artificial flaw. The tensile properties, compressive strength, water permeability and shrinkage of PDCC with various volume contents and size of rubber particles were measured. The test results show that incorporation of rubber particle will reduce the compressive strength and first cracking strength of PDCC. With increased size and volume of rubber particles, the compressive strength is increased. To achieve maximum tensile ductility, optimum rubber content and size should be employed. Water permeability is found to be similar for various PDCC mixes with or without rubber addition. The content of rubber particle plays a significant role on the dry shrinkage of PDCC, while the particle size only has a slight effect.

Introduction

Traditional concrete, whether classified as normal concrete, high strength concrete or high performance concrete, is generally brittle in nature. The ease of cracking limits the application of cementitious materials and affects the long-term durability of structures. Over the years, many research studies have been performed to modify the brittle behavior of cementitious composites, and the incorporation of fibers to increase the strain capacity is the most common approach. In traditional plain concrete, tensile failure is usually accompanied by the formation of a single crack, with the post-cracking tensile stress dropping to zero at a very small crack opening. In comparison to plain concrete, fiber reinforced concrete (FRC) exhibits significant post-cracking tensile resistance due to the bridging effects of fibers. However, as the residual stress is decreasing with crack opening, only a single crack will form under direct tension. Although the incorporation of fibers can improve various properties of the material, including flexural and shear capacity, energy absorption, ductility of failure, etc, failure still occurs through the formation of discrete cracks with significant openings. In the early 1990's, Li, Leung and Wu[1-4] investigated the mechanics of crack bridging and proposed the fundamental theory for the development of pseudo-ductile cementitious composites (PDCC), which are composites exhibiting strain-hardening behavior in tension, with the formation of closely-spaced multiple fine cracks rather than widely opened discrete cracks. The design of PDCC is based on two physical conditions: (1) the energy-absorption rate G_r in the fiber-bridging zone behind the crack tip is at least 10 times the value of G_{tip}, which is the energy absorbed at the crack tip, and (2) the flaw size in the material is greater than a certain critical value governed by microscopic material parameters. The first condition ensures that the fracture failure process is governed by the bridging fibers while the second condition ensures subsequent formation of closely-spaced cracks after the first crack is formed. Hereafter, Li and co-workers further developed the theories [5,6] and came up with practical approaches for the making of PDCC, such as tailoring of interfacial properties [7], reduction of matrix

toughness by limiting the particle size in the cementitious matrix [8] and the incorporation of uniformly distributed artificial flaws [9]. Specifically, artificial flaws are introduced in the matrix by the incorporation of bubbles, glass or plastic beads, lightweight aggregates, etc. This will result in reductions in matrix toughness and first-cracking strength as well as making the cracking strength more uniform in different parts of the material, which facilitates the formation of closely-spaced cracks. With low stiffness and weak bonding to the cementitious matrix, rubber particles should be useful for the making of PDCC as the artificial flaws.

Rubber is not biodegradable and its burning can result in the production of carcinogenic gas. With the growing use of automobiles in China, the rapidly increasing amount of waste rubber from tyres has become a big environmental problem. Now rubber particles produced from waste rubber have been used for making concrete, and results in the literature show that concrete with rubber particles exhibits improved flexibility, ductility, energy absorption [10, 11], impact resistance and dissipation under dynamic loading [12], Mortar with 5% or 10% fine rubber ash was also found to exhibit improved resistance to freezing and thawing and chloride diffusion [13]. Due to these excellent properties of cementitious composites with rubber particle, PDCC with rubber particles are expected to combine high tensile performance, dynamic properties and resistance to freezing and thawing etc.

In the present study, PDCC specimens were prepared to study the effect of rubber incorporation on various properties. Control specimen without rubber particles was first prepared and tested. In other specimens, part of sand or filler was replaced by fine rubber particles as the artificial flaws. To identify the appropriate content and size of rubber particles for optimal performance, rubber particles of different particle size distribution were added at different contents. Due to relative low water permeability and high dry shrinkage to PDCC, properties including compressive strength, tensile performance, water permeability and dry shrinkage were measured to obtain a comprehensive understanding on the effect of rubber particles.

Properties of Raw Materials

Portland cement P·II52.5 and the high activity fly ash was employed in this study. The particle size of fly ash is mainly within 2~10μm and the content of major active components (including SiO_2, Al_2O_3 and Fe_2O_3) reaches 76.1%. According to ASTM C311-04, the active index of compressive strength at 7 days, 28 days and 90 days are 86%, 84% and 96% respectively, and the content of calcium silicates and the ratio of Ca/Si is 79% and 3.0 respectively. Silica fume, silica filler and silica sand were also employed and their respective range of particle size are 1~20μm, 1~15μm and 50~200μm. To provide pseudo-ductility, polyvinyl alcohol fiber (PVAF) (Kuraray Limited Corporation, Japan) was used. Its density, length and diameter are 1.3g/cm^3， 12mm and 38μm respectively. Superplasticizer (Sp) with 23% solid content and rubber particles (R) with various maximum particle sizes of 0.4mm, 0.2mm and 2mm were also used in the specimens.

Test Procedure

The tensile performance and compressive performance are obtained respectively from specimens 350×50×15mm and 40×40×40mm in size. Note that the size of cast members may not be exact so the actual dimensions of each specimen were measured by vernier caliper before testing to obtain accurate values for the calculation of material parameters. The specimen was demoulded after 24 hours of wet curing in the laboratory, where the temperature was about 20±2℃, and then cured in water at temperature of about 26 ℃。

Before the performance of tensile testing, four 100x50mm CFRP sheets were bonded to both surfaces at the ends of the tensile specimens. Then, four 70x50mm aluminum plates were also glued to the ends. Testing was performed under displacement control in the MTS810 system and the displacement rate was 0.15mm/min. During testing, the parts covered with aluminum plates were gripped, and strain was measured within the middle 150mm (which was not reinforced). The first

crack strain ε_{Tfc} and the ultimate strain ε_{Tu} were taken to be the strain values corresponding to the first crack stress σ_{Tc} (where the stress vs strain shows a sudden deviation from linearity) and ultimate stress σ_{Tu} (which is the maximum stress reached by the specimen), respectively. In many specimens, after the ultimate stress is reached, softening occurred at a very slow rate. The post-peak stress vs strain behavior can contribute to significant energy absorption and toughness improvement of the material. Moreover, under other kinds of loading (e.g., bending), the slow decrease in post-peak tensile stress can result in hardening behavior in the moment vs curvature relation. As the rate of softening is of practical significance, we defined the maximum strain ε_{Tm} as the strain when the ultimate stress descends up to 90%, and measured it for each of the tested specimen. A high value of ε_{Tm} implies slow softening.

Water permeability test was conducted using the falling head setup, which was originally developed by Ludirdja[14]. With this set-up, the specimen is sandwiched between two water reservoirs and pressure is generated by water in a long vertical tube placed above the upper reservoir. Assuming laminar flow after the specimen is saturated with water, and Darcy's law can be applied to derive an equation for calculating the coefficient of water permeability (k_w). During the test, the height of water in the tube was measured as a function of time (t).

The drying shrinkage was measured according to ASTM C596-01. Members 25mm×25mm×280mm in size were cast and kept wet in the molds for one day. After demoulding, the specimens were cured in water for two additional days. The initial length was then obtained and the specimens was placed in a room with controlled environment, where the temperature and relative humidity were kept at about 27±2^{O}C and 50±5% respectively. The change of specimen length was accurately measured at specific times for the calculation of drying shrinkage.

To study the effect of rubber particle size and content on the performance of PDCC, PDCC with various compositions as shown in table 1 were prepared and tested. In all cases, an appropriate amount of super-plasticizer was added to achieve the required workability; and 2 volume percent of PVAF was added to achieve high ductility. CON is the control PDCC, and in SR3.5, SR7 and SR11, rubber particles including 3.5%, 7% and 11% in volume of the cementitious composites was employed by the decrease of sand content, respectively. For SR16, the sand content is the same as that of SR11, but the filler is also replaced by rubber particles.

In the mixes in Table 1 with rubber particles, the maximum particle size was 0.4mm. In addition to these mixes, two additional mixes were prepared to study the effect of particle size. These mixes, which had the same composition as SR11, were denoted as S2R11 and S0.2R11 and the maximum particle size was 2mm and 0.2mm respectively.

Table1 MIX PROPORTION OF PDCCS WITH VARIOUS CONTENTS OF RUBBER PARTICLES (kg/m^3)

Test Results and Discussions

Mechanical Properties of PDCCs with Various Fractions of Rubber Particles

The test results are showed in table2. To obtain the tensile behavior and compressive strength, at least three specimens were tested at each specified age. The control PDCC specimens were tested at 7, 28 and 90 days. Long-term curing was found to have a significant effect on the tensile ductility. For the specimens with rubber particles, testing was performed at 7 days and 28 days.

It can be observed from Table2 that incorporation of rubber particle will reduce the compressive strength and tensile strength of cementitious composites. With increasing content of rubber particles from 3.5% to 16%, the 28-day compressive strength decreases by 17% to 80% while the tensile

strength decreases by 16% to 56%. With increasing rubber content, the ultimate strain does not exhibit a clear trend. The highest tensile strain at 28 days (2.15%) was achieved with 11% of rubber particles. Fig.3 shows the typical stress vs. strain curves of PDCC with 3.5 % and 11% of rubber particles with different curing conditions.

Table2 MECHANICAL PROPERTIES OF PDCCS WITH DIFFERENT VOLUME FRACTION OF RUBBER POWDER

		σ_{Tfc}(MPa)	σ_{Tu}(MPa)	ε_{Tfc}(%)	ε_{Tu}(%)	ε_{Tm}(%)	σ_{com} (MPa)

Fig1 shows the stress vs. strain curves of SR3.5 at different age and SR11, SR7 at 28 days. It can be observed from Fig.1 that for some specimens, such as SR3.5 and SR7-28, high tensile stress can still be maintained up to a strain far beyond the ultimate strain corresponding to peak stress. For example, for the specimen SR3.5-7 shown in Fig.1, the strain ε_{Tu} corresponds to the ultimate strength is only 0.02, which is equal to the first cracking strain, as maximum stress occurs at first cracking in this case. However, the maximum strain ε_{Tm} (when the post-peak stress is 90% that at the peak) reaches value of 0.99. During the test, although the stress was dropping slowly after first cracking, it is interesting that some fine cracks were found to form away from the main crack which became visible after the peak stress was reached. Specimens within the same group may have different degrees of variation. The three SR11 specimens exhibit similar ultimate failure strain and tensile strength. However, for the SR7 specimens, despite the similarity in tensile strength, there is a large scatter in the ductility. In fact, the control specimens also show a high variation in the ultimate strain, with a high value of 1.66% for one specimen, and much lower values of 0.49% and 0.38% for the other two.

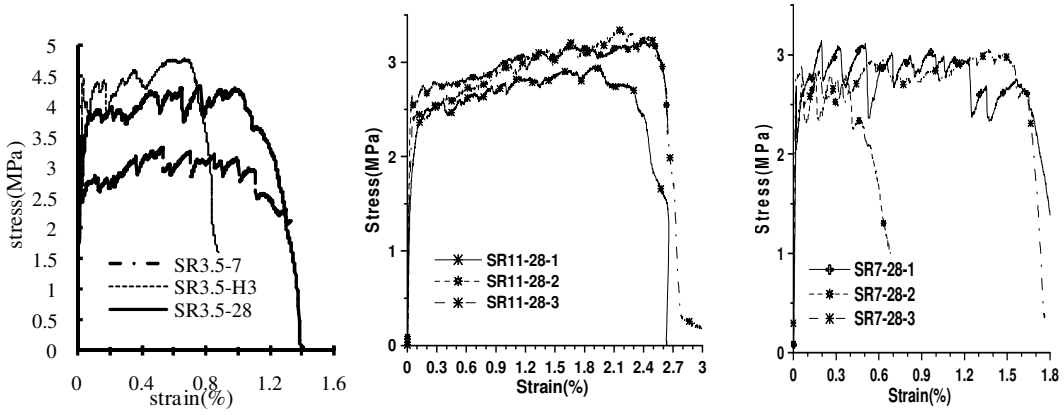

Fig.1 Typical Stress vs. Strain Curves of SR3.5 at Different Age and SR11, SR7 at 28 days

In order for PDCC to have high ductility, a large number of transverse cracks should be able to form under tension. In the ideal situation where the first cracking strength is uniform in every section along the length of the specimen, and is lower than the maximum stress provided by fiber bridging, closely spaced cracks will form, with the crack spacing limited by the distance required for fibers to transmit stresses back into the matrix. In reality, however, flaws of different sizes exist in different

parts of a member. Since first-cracking strength is governed by the initial flaw size, it varies along the length of the specimen. In this case, only the sections with relatively large flaws are able to crack. With a significantly smaller number of cracks than the ideal case, the ductility is greatly reduced. Also, because the uniformity of strength can vary from one specimen to the next, a large variation in the test results is often observed.

The incorporation of small rubber particles serve to introduce artificial flaws in the cementitious matrix. A uniform distribution of rubber particles over the specimen can homogenize the first-cracking strength along the length. It is obvious that a certain minimum volume fraction of rubber particles is required to ensure the presence of artificial flaw in every section of the member. However, when the volume fraction is too high, some particles may get very close to one another and induce the formation of large cracks in certain sections. The first-cracking strength then becomes less uniform again. Based on the above arguments, an intermediate volume of rubber particles is optimal for ductility. Also, when the particles are distributed in such a way to give similar strength in all sections, the variability in test results (for specimens with the same composition) is reduced.

Mechanical Properties of PDCCs with Various Sizes of Rubber Particles

The test results for PDCC with different sizes of rubber particles are listed in Table3.

Table3 Mechanical Properties of PDCCs with different particle size of rubber

		σ_{Tfc}(MPa)	σ_{Tu}(MPa)	ε_{Tfc}(%)	ε_{Tu}(%)	ε_{Tm}(%)	σ_{com} (MPa)
S2R11	7-day	1.82	2.22	0.027	0.29	0.67	27.2
	28-day	1.62	1.93	0.048	0.24	0.41	35.5
	H3d	3.00	3.08	0.032	0.05	0.28	42.0
SR11	7-day	2.19	2.72	0.034	1.04	1.4	24.8
	28-day	2.31	3.18	0.051	2.15	2.49	31.4
	H3d	3.28	3.57	0.041	0.20	0.34	37.0
S0.2R11	7-day	1.31	1.85	0.043	0.77	1.18	21.5
	28-day	1.88	2.69	0.023	0.86	1.37	28.9
	H3d	2.67	3.11	0.055	0.38	0.71	30.1

Comparing the compressive strength of S2R11, SR11 and S0.2R11 at the same age, it can be observed that a larger size of rubber particle gives rise to a higher strength. However, the first cracking strength does not follow the same trend – it is highest when rubber particles with maximum size of 0.4mm were employed. A plausible explanation lies in the different failure modes of cementitious materials in compression and tension. Under compression, many cracks will form in the member and final failure is caused by coalescence of the cracks. As individual cracks are likely to be arrested by rubber particles, the cracks can only link together after they have propagated around the particle. With larger particles, the applied compression for this happen is also higher. Tensile failure occurs in the weakest section and the first cracking strength increases with the toughness of the material but decreases with the maximum flaw size. With small rubber particles, the inherent flaw size is small but so is the fracture toughness. With large particles, the toughness is higher (Note: this has been shown by test results on specimens containing rubber particles but no fibers) but the flaw size is also large. The first cracking is hence highest with an intermediate particle size.

The tensile ductility of PDCC is found to be highest with the 0.4mm rubber particles. When the rubber particle size is too small, it may be even smaller than the air voids inside the cementitious matrix. In this case, the flaws resulted from the incorporation of rubber particles do not dominate fracture failure. The incorporation of small particles will hence have little effect on the ductility. When very large particles are used, there are two unfavorable effects on tensile ductility. Firstly, with the same volume fraction, larger particle size implies a smaller number of particles, which may affect the uniformity of particle distribution. Secondly, with a larger particle size, the fracture toughness (and hence the energy absorption) at the crack tip is also increased. As multiple crack formation and the corresponding ductility is favored by a high ratio of energy absorption behind the crack tip and that at the crack tip, high crack tip toughness will result in reduced ductility. With the above arguments, one can explain the achievement of maximum tensile ductility at an intermediate rubber particle size.

Water Permeability

Water permeability of a particular composition of PDCC has been reported by Lepech and Li [15] to be around $1x10^{-11}$ m/s, which is on the high side of values for normal concrete, which ranges from 10^{-12} to 10^{-11} m/s [16]. As rubber particles have smooth surfaces and do not have strong bond with the hydration products of cement, there is a concern that the particle/cement interface may serve as a preferential path for water permeation. If this is indeed the case, the incorporation of rubber particles will further increase the water permeability of PDCC, and make the material more permeable than normal concrete. To see if this is indeed a problem or not, the water permeability of SR3.5, SR7, SR11 and SR16 after 28 days of curing was also measured, and the test results were 4.72, 4.04, 4.92 and 4.06 $x10^{-12}$m/s respectively. It can be seen that the coefficient of water permeability for various PDCC mixes is close to one another, with values between 4 to 5×10^{-12} m/s. These values are lower than that given in [15] and within the range of normal concrete. According to our results, the incorporation of rubber particles does not necessarily produce a composite with high water permeability.

Shrinkage of PDCCs with Rubber Particles

Fig.2 shows the effect of rubber particle volume on dry shrinkage. Due to the absence of coarse aggregates, the ultimate dry shrinkage strains of all mixes (with or without rubber) are very high and exceed 10×10^{-4}. As expected, the dry shrinkage increases rapidly in the first 14 days, and slowly approaching an asymptotic value. The dry shrinkage strains of specimen SR7, SR11, SR16 at 28 days are 11.17×10^{-4}, 14.61×10^{-4} and 19.85×10^{-4}, respectively, while the corresponding values at 91 days are 13.36×10^{-4}, 16.61×10^{-4} and 23.66×10^{-4}. According to the test results, drying shrinkage of PDCC increases rapidly with content of rubber particle in the mix. For SR11 with S0.2R11, their drying shrinkage strains at 28 days are 14.61×10^{-4} and 13.95×10^{-4}, respectively, and the values at 91 days are respectively 16.61×10^{-4} and 16.02×10^{-4}. The results indicate that the particle size has only a slight effect on the dry shrinkage of PDCC. In summary, when rubber particles are added to PDCC for the generation of artificial flaws, drying shrinkage may be significantly increased. In future work, the combined use of rubber particles with shrinkage-compensating cement should be studied.

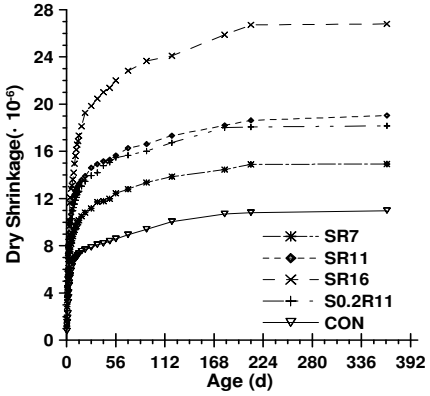

Fig.2 Effect of Rubber Particle on Dry Shrinkage of PDCCs

Conclusion

Pseudo-ductile cementitious composites (PDCC) are composites showing strain hardening behavior under direct tensile loading. Its ductility (defined as the strain corresponding to maximum stress) depends on the spacing of multiple cracks that can form in the hardening regime. Incorporation of artificial flaws in the composite can facilitate the formation of closely spaced multiple crack. In the present study, rubber particles were added in PDCC mixes for the generation of artificial flaws. Specimens were prepared with different volume fractions and sizes of particles were employed, and tested for mechanicals properties, water permeability and dry shrinkage. The following findings from the test results can be highlighted:

(1) The compressive strength and first cracking strength of PDCC generally decreases with increasing content of rubber particles. The tensile ductility, however, is maximal at an intermediate volume fraction of rubber particles. With increasing rubber particle size under fixed particle content,

the compressive strength is increased but the first-cracking strength and tensile ductility attain maximum values at an intermediate particle size. In the design of PDCC, maximizing of material ductility is often the major goal, and rubber particles of optimal volume and size should be employed. In the present study, the 11% rubber particles with particle sizes of 0.4mm are optimal.

(2) Water permeability for various PDCC mixes with rubber particles is close to the value for normal concrete.

(3) The dry shrinkage of PDCC increases greatly with the volume content of rubber particles but is insensitive to rubber particle size.

Back Analysis of Thermal Parameters of Mass Concrete and Its Application Based on Micro-genetic Algorithm

Guo Rong CHEN[1],Bei YANG[2,a]

Department of Engineering Mechanics , Hohai University, Nanjing, 210098, China

[a] beibeibinbin0416@163.com

Keywords: concrete; thermal parameter; back-analysis; simulating calculation; micro-genetic algorithm

Abstract: The value of thermal parameter is very crucial in simulating analysis on temperature control for mass concrete. The inverse analysis on some practical project is done by genetic algorithm and finite element method on the basis of observational data of temperature on the site. The temperature control simulation calculation is performed based on parameters obtained from inverse analysis on this project, so that the temperature distribution is consistent basically with the practical one. With improvement of micro-genetic algorithm, the genetic algorithm becomes globally-optimal by changing the optimal reserving and re-starting strategies. The results show this method is very practical in high precision of calculation in mass concrete parametric inversion.

Introduction

Concrete cracks easily to imperil the structure safety and normal use at a certain temperature as a brittle material with low tensile strength. So the temperature calculation for mass concrete is very indispensable, and the correct selection of concrete thermal parameters is crucial to temperature calculation and control measures for crack prevention[1, 2]. However, the thermal parameters of concrete cannot reflect practical situation as they are usually obtained on site, laboratory or experience. For this, the inverse analysis on these parameters is performed. This is conducive to avoiding complex outside conditions and limited experiments, so that parameters reflecting concrete thermal properties are obtained. However, because of extreme non-linearity and complexity in question, the traditional optimization algorithm often gets into the locally optimal solution by inverse analysis, with a too slow rate of convergence even without convergence. For above reasons, it is the key how to select an effective searching method in analysis.

The genetic algorithm put forth by Professor J.H. Holland is applied soon in inverse problem as it is global and not easy to fall into local optimum. In particular, it is applicable to handle the complex non-linearity which is hard to be dealt with by the traditional searching method. Eiben A.E et al. proved convergence of genetic algorithm[3]. Charles established the retrieval method of initial-value and boundary-value problems [4]. Zhang Yuxin proposed the universal methods such as main thermal parameters and thermal exchange coefficient for inverse steady-state temperature field of concrete[5]. For complex engineering problems, the frequency of positive calculation increases because the rate of its convergence is too slow or the scale of population is oversized. In addition, it is weak in the local searching of algorithm and poorer in stability of variables to be optimized. Krishnakumar K. [7] improved basic genetic algorithm, and proposed the micro-genetic algorithm (MGA) which is applicable for solution of complex engineering—reducing number of individuals of population to some extent. Liu Yinfang et al. improved the micro-genetic algorithm to ensue population diversity by designing restarting function [8]. Li Yi et al. improved the micro-genetic

algorithm to avoid local optimum by the optimal reserving strategy [9]. I compiled the inverse analytical procedures of parameters of the three-dimensional unstable temperature field, retaining optimal individuals instead of mutation operation by binary coding, roulette selection, single-point cross and optimal reserving strategy.

Principles

Temperature filed finite element method

When the transient temperature field satisfies requirements of all possible temperature fields in the coercive boundary condition $T = f(t), x \in s_1$ and the initial condition $(T)_{t=0} = f(x, y, z), x \in V$, the true temperature field can meet the $\delta\Pi = 0$, where the functional is expressed as follows:

$$\Pi = \int_V \left\{ \frac{\alpha}{2} \left[\left(\frac{\partial T}{\partial x} \right)^2 + \left(\frac{\partial T}{\partial y} \right)^2 + \left(\frac{\partial T}{\partial z} \right)^2 \right] + \left(\frac{\partial T}{\partial t} - \frac{\partial \theta}{\partial t} \right) T \right\} dv + \int_{s_2} \frac{1}{c\rho} T \overline{q}_n ds - \int_{s_3} \overline{\beta} T \left(T_a - \frac{1}{2} T \right) ds \quad (1)$$

The transient temperature field is a function of space and time, and its solution domain is divided into finite element gridding. The temperature function for each element is obtained by the interpolation of the node temperature value of this element. The functional after convergence of finite element is equal to the sum of element functionals, i.e.

$$\begin{aligned} \Pi &= \int_V \left\{ \frac{\alpha}{2} \left[\left(\frac{\partial T}{\partial x} \right)^2 + \left(\frac{\partial T}{\partial y} \right)^2 + \left(\frac{\partial T}{\partial z} \right)^2 \right] + \left(\frac{\partial T}{\partial t} - \frac{\partial \theta}{\partial t} \right) T \right\} dv + \int_{s_3} \overline{\beta} \left(\frac{1}{2} T^2 - T_a T \right) ds \\ &= \sum_e \int_V \left\{ \frac{\alpha}{2} \left[\left(\frac{\partial T}{\partial x} \right)^2 + \left(\frac{\partial T}{\partial y} \right)^2 + \left(\frac{\partial T}{\partial z} \right)^2 \right] + \left(\frac{\partial T}{\partial t} - \frac{\partial \theta}{\partial t} \right) T \right\} dv + \sum_e \int_{s_3} \overline{\beta} \left(\frac{1}{2} T^2 - T_a T \right) ds \end{aligned} \quad (2)$$

Where, $\alpha = \frac{\lambda}{c\rho}$, $\overline{\beta} = \frac{\beta}{c\rho}$, and thermal rising math model is Index II:

$$\theta(\tau) = \theta_0 \times \left(1 - e^{-a\tau^b} \right) \quad (3)$$

Genetic algorithm principle

The genetic algorithm is essentially a searching method based on natural selection mechanism and genetics[12]. The MGA is improved greatly in algorithm structure so as to ensure GA global searching ability. The basic operation strategy for genetic algorithm contains crossover and variation, where, the crossover operation is uppermost genetic one in genetic algorithm. Based on crossover probability, each pair of individuals exchange some individual chromosomes each other at this point, forming two new individuals. Some variation operations are cancelled and some GA operations are added in MGA, for example, the optimal reservation. There is a smaller scale of populations in MGA, and its number of populations may be taken as 5-10 (20 populations at least for GA). As a result, the calculated quantity decreases greatly.

Improvement of micro-genetic algorithm

Theoretical analysis

I improved the optimal reserving strategy in MGA, that is, reserving the best or optimal individuals fully and storing them to form the optimal reserved individuals in order for selection of the next generation. By this way, fast convergence is available in case of forming the locally-optimal solution. The setting temporary storage part is used to store the best individuals for comparison, and setting optimal reserved individuals are used to store all the best individuals. By this way, the best individuals selected in each generation of cycle can be stored integrally in the end.

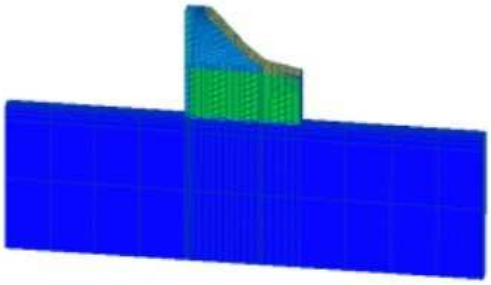
The restarting operation is set in MGA so as to keep the population diversity. The restarting strategy is performed in calculation of some generations. By confining the restarting distance, not only can all excellent genes be reserved by the restarting strategy, but also diversity of superior genes can be realized. By this way, interference of the individuals with the most distinct local superiority in the population can be avoided to diversity of the population.

Inverse analysis model

The temperature inverse analysis model is applied because the thermal parameters are strongly related to temperature in the calculation of temperature field and temperature is measured easily. Supposing inverse parameters used in simulation calculation are the same as the actual ones of the material, then $T_{ij} = T_{ij}^0$, ignoring the errors of numerical calculation and measurement of the model. Generally speaking, the square root of square difference is taken as the inverse objective function as the calculated and measured values of temperature field are not strictly equal, i.e.

$$F = \sum_{i=1}^{m}\sum_{j=1}^{n} \omega_{ij} \sqrt{\left(T_{ij}(X) - T_{ij}^0\right)^2}$$

Where, ω_{ij} stands for weighting coefficient, T_{ij} is the calculated temperature value, T_{ij}^0 is the measured temperature value, i is the serial number of observing point, and j is the serial number of observing time, X is inverse parameter vector; $X(x_1, x_2, x_3, \cdots) = X(a, b, \theta_0, \cdots)$. There is a certain estimated range based on experience or experimental inverse parameter, i.e. the constraint condition is:



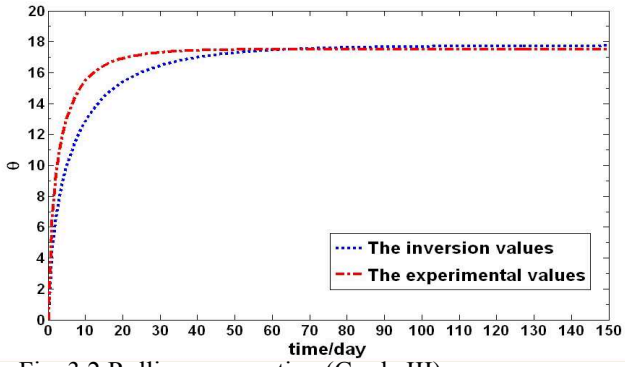
$$x_i^l \le x_i \le x_i^m \qquad (i = 1,2,3, \ldots)$$

The calculation process is shown:

Step 1 Determine initial population quantity and initial value space, and generate the initial population within the initial value space. Each individual is expressed as the gene coding of chromosome. Step 2 Determine the fitness function, obtain the temperature value and fitness value of each individual by calculating the temperature field finite element, and select individuals based on fitness values. The individual selected probability is greater than that of small fitness individual. Step 3 Generate new individual and select the optimal reserving value generated from best individuals in the population based on a certain crossover probability and crossover operation method. Step 4 Judge whether the condition of convergence is satisfied or not. If yes, turn to Step 5;

if no, return to Step 2. Step 5 Judge whether it is local convergence or not, and perform the comparison of distance. If it is local convergence, restart it, then turn to Step 2; otherwise, perform Step 6. Step 6 Store the optimal reserving value into the temporary memory, and judge the terminal condition is satisfied or not. If yes, output best individuals and their optimal solution, and end the calculation; otherwise, write the optimal value in the temporary memory into the optimal reserved part, and turn to Step 2 after the optimal reserved part and stochastic part generate the population together.

Numerical example



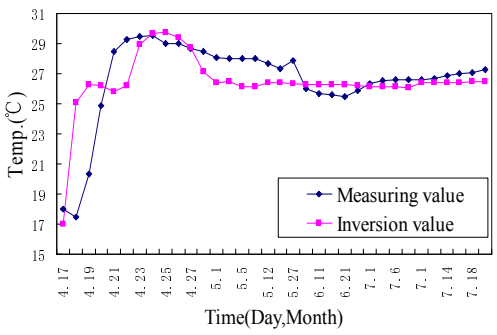


Fig. 3.1 Grid chart of overflow dam section Fig. 3.2 Rolling compaction (Grade III)

The adiabatic temperature rise curve obtained by inversion is shown in Fig. 3.2 The initial phase of inverse adiabatic temperature rise curve is gentler than the experimental curve, and the peak temperature rise is 0.53℃ higher than the experimental value. Figure 3.3and3.4 shows two randomly selected temperature measuring point comparison chart.

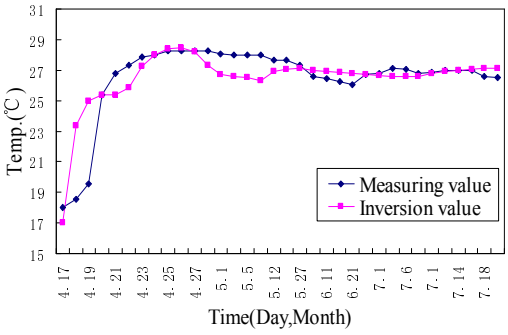

Fig. 3.3 Inverse temperature value at 06 Fig. 3.4 Inverse temperature value at 31

Conclusions

The thermodynamic parameter inversion optimization is performed for the project by improving micro-genetic algorithm and combining three-dimensional unstable temperature field, and the results show as follows:

1. This algorithm can be well applied to finish parameter optimization quickly to converge to the optimal solution. So the local optimum can be avoided, and calculation time and accuracy are improved greatly. It has ability to solve engineering cases, is worth popularizing and applying.

2. The inverse analysis is performed for the engineering project and feedback analysis to enable computer feedback work more realistic to reflect the practice, so that play a more reliable and guiding significance role. The method are economically reasonable and technically feasible, which can be widely applied to the engineering of temperature control in similar in the future.

Key words: GFRP bars; tensile strength; prediction; concrete beams; solution method

Abstract: It is necessary to research on the long term structural behavior of GFRP bars in concrete by limited samples. The two models, Arrhenius Equation and Fick's Law were compared to form a long-term durability prediction thinking. Based on the work and ideas of the prior researchers, a detailed derivation of the iterative equation on the Bayesian prediction was conducted. Especially, a new likelihood function was set up to solve the long term behavior prediction of GFRP bars in concrete with less information. Then a new and effective solution method was developed. The residual strength behavior of GFRP bars in concrete beams after seven years' environmental exposure was analyzed. The results showed that the theoretical predictions and experimental data were very close and theoretical prediction model was reasonable.

INTRODUCTION

Considerable research has been conducted in the past thirty years to assess the durability of GFRP bars in reinforced concrete structures. It was recognized that GFRP bars were susceptible to moisture, alkaline solutions and elevated temperature. In particular, the durability of GFRP bars could be affected by the alkaline environment of concrete. The material aging may occur in the fiber, matrix, and their interface individually or simultaneously. Much work was highlighted on the short-term performance of GFRP reinforced concrete structures.

Homman studied the durability of GFRP bars under different moisture and temperature environments. The results showed that the above all kinds of environmental factors could reduce the GFRP's mechanics properties more or less (Homam S M. 2005). Chen, Davalos and Ray (2005,2006) and Yousef (2013) presented the short-term test results of a durability study on GFRP reinforcing concrete structures by accelerated test methods. GFRP reinforcing bars were exposed to different solutions at elevated temperature combined with wetting and drying, and freezing and thawing cycling, which were designed to simulate the adverse conditions in the field.

The researchers pointed out that the application of the Fick's law and the Arrhenius equation were of limitations. In order to explain the two theories, we have a further theoretical discussion.

(1) Prediction model based on Fick's Law

Fick-type model has been used to predict the residual strength of GFRP bars embedded in concrete. Shen and Springer (1986) recommended that the diffusion coefficient needed in Fick's law be obtained by using the following equation.

$$D = \frac{\pi r^2}{16}\left(\frac{M_2 - M_1}{M_m}\right)^2\left(\frac{1}{\sqrt{t_2} - \sqrt{t_1}}\right)^2 \quad (1)$$

Where D is the diffusion coefficient in the composite material; M_1, M_2 and M_m are the moisture content of the bar (in percent) at time t_1, t_2, and at saturation, respectively.

Katsuki and Uomoto (1995) proposed a prediction model based on Fick's Law. The authors assumed that the tensile strength of GFRP bars could be determined quantitatively by the amount of alkali penetration area into the bars and recommended that the depth of penetration be calculated by using the following equation:

$$X = \sqrt{2 \cdot D \cdot C \cdot t} \quad (2)$$

Where X is the depth of penetration, C is the alkaline concentration (percent), t is the curing time, and D is the diffusion coefficient.

The authors assumed that as glass fibers were exposed to the diffusing solution these fibers exhibited complete failure and no longer contributed to the bar's capacity. By using this assumption the authors proposed the following equation for estimating the residual strength:

$$\sigma_t = \left(1 - \frac{\sqrt{2 \cdot D \cdot C \cdot t}}{R_0}\right)^2 \cdot \sigma_0 \quad (3)$$

Where σ_o and σ_t are the tensile strength before and after exposure (stress units), respectively, and R_0 is the radius of the GFRP bars.

Trejo et al (2009) reported that the assumption of complete loss of glass fiber capacity probably overestimated the loss of bar capacity and proposed an exposure factor λ, to account for this time-dependent deterioration of the bond between the glass and resin. The equation (3) was rewritten as follows:

$$\sigma_t = \left(1 - \frac{\sqrt{2 \cdot D \cdot \lambda \cdot t}}{R_0}\right)^2 \cdot \sigma_0 \quad (4)$$

Although the model that based on Fick's law satisfied the durability prediction of the GFRP composites to a certain extent, the assumption that the matrix and the glass fibers in the aggressive area would completely fail deviated from the fact (Dejke 2001).

(2) Prediction model based on the Arrhenius law

Arrhenius equation has been widely used to establish correlation between degradation data from laboratory accelerated aging tests and service-life of field structures. The Arrhenius equation reveals a good correlation between the temperature and the rate of diffusivity and chemical reaction. The Arrhenius equation is shown as follows (Litherland 1981, Nelson1990) :

$$k = A \exp\left(-\frac{\Delta E_a}{RT}\right) \quad (5)$$

Where k is the degradation rate (1/time), A is a constant of the material and degradation process, E_a is the activation energy; R is the universal gas constant and T is the Kelvin temperature. The equation (5) can be transformed into:

$$\frac{1}{k} = \frac{1}{A} \exp\left(-\frac{RT}{\Delta E_a}\right) \quad (6)$$

$$\ln\left(\frac{1}{k}\right) = \frac{E_a}{R} \cdot \frac{1}{T} - \ln(A) \quad (7)$$

It is supposed that aging mechanism is not changeable with time and temperature in Arrhenius equation. In practice, new aging mechanism may be produced with temperature becoming higher and higher. So there is error for this method.

Reliability theory equation of long-term performance prediction of GFRP bars

Trejo et al (2009) introduced exposure factor λ in prediction model (4) to make the model more flexible to fit the experimental data, which was modified as follows.

$$\sigma_t = \left[1 - \lambda\left(\frac{D \cdot t}{R_0^2}\right)^{\alpha}\right] \cdot \sigma_0 \quad (8)$$

Where each term has the same definition as in Eq. (4). To account for the uncertainty of σ_0 and σ_t, Eq. (8) was then modified as follows.

$$\sigma_t(D,R_0,\lambda,\alpha,s,s_0)=\left[(1+s_0\varepsilon_0)-(1+s\varepsilon)\lambda\left(\frac{D\cdot t}{R_0^2}\right)^{\alpha}\right]\mu_{\sigma_0} \quad (9)$$

Where stochastic error ε and ε_0 obey N~(0,1) distribution statistically. Because ε and ε_0 are mutual independent, the covariance is 0. $s_0\ \varepsilon_0$ obeys $(0, s_0^2)$ distribution. $s\ \varepsilon$ obeys $(0, s^2)$ distribution. $s\varepsilon\lambda\left(Dt/R_0^2\right)^{\alpha}$ obeys $\left(0, s^2\lambda^2\left(Dt/R_0^2\right)^{2\alpha}\right)$ distribution. In equation (9), $s_0\varepsilon_0 - s\varepsilon\lambda\left(Dt/R_0^2\right)^{\alpha}$ is error term. Because ε and ε_0 are mutual independent with 0 covariance, the standard deviation is $\sqrt{s_0^2+s^2\lambda^2\left(Dt/R_0^2\right)^{2\alpha}}$. Let $x=(D, R_0)$ as a basic variable, $\Theta = (\lambda, \alpha, S_0, S)$ as a vector of unknown empirical model parameters. Based on these, equation (9) can be transformed as:

$$\frac{\sigma_t(x,\Theta)}{\mu_{\sigma 0}}=\left[1-\lambda\left(\frac{D\cdot t}{R_0^2}\right)^{\alpha}\right]+\sqrt{S_0^2+S^2\cdot\lambda^2\left(\frac{D\cdot t}{R_0^2}\right)^{2\alpha}}\cdot\varepsilon \quad (10)$$

The key of using the prediction equation is to determine the unknown parameter λ, α, S_0, S. Therefore, the objective of this paper is to determine the parameters based on a small number of long-term tensile strength empirical data of GFRP bars.

A effective solving method based on Bayesian rule

The unknown model parameters λ, α, S_0, S are empirical and have no direct physical meaning. These parameters are used to fit the experimental data. The parameters are estimated using the Bayesian rule.

$$f(\Theta)=\gamma L(\Theta)p(\Theta) \quad (11)$$

Where $p(\Theta)$ is the priori distribution of unknown parameter Θ, $L(\Theta)$ is the likelihood function that represents the information on the parameter Θ from the tensile strength data y. $f(\Theta)$ is the posterior distribution of Θ. γ is a normalizing factor:

$$\gamma=\frac{1}{\int L(\Theta)p(\Theta)d\Theta} \quad (12)$$

It is difficult to form an effective distribution without enough long term tested tensile strength values. In this case, we can assume it obeys even distribution on a certain interval if the unknown parameters are continuous random variables. Therefore, it is assumed the priori distribution $p(\Theta)$ obeys (0-1) distribution. In this way, Likelihood function can be derived as follows:

$$L(\Theta)=\prod_{i=1}^{n}P\left\{\frac{\sigma_{t_i}(x,\Theta)}{\mu_{\sigma_0}}=\left[1-\lambda\left(\frac{D\cdot t_i}{R_0^2}\right)^{\alpha}\right]+\sqrt{S_0^2+S^2\cdot\lambda^2\left(\frac{D\cdot t_i}{R_0^2}\right)^{2\alpha}}\cdot\varepsilon\right\} \quad (13)$$

Based on (11)-(13), then

$$y=\frac{\sigma_{t_i}(x,\Theta)}{\mu_{\sigma 0}} \quad (14)$$

$$\mathrm{f}(\lambda,\ \alpha,\ S_0,\ S)=\left[1-\lambda\left(\frac{D\cdot t_i}{R_0^2}\right)^{\alpha}\right] \quad (15)$$

$$A_1\cdot\varepsilon=\sqrt{S_0^2+S^2\cdot\lambda^2\left(\frac{D\cdot t_i}{R_0^2}\right)^{2\alpha}}\cdot\varepsilon \quad (16)$$

So equation (10) can be transformed as below.

$$y=\mathrm{f}(\lambda,\ \alpha,\ S_0,\ S)+A_1\cdot\varepsilon \quad (17)$$

Based on the equation (17), an analysis program can be developed to determine the unknown parameters in the long-term value prediction equation of GFRP bars tensile strength.

Numerical examples

Trejo et al.(2009) exposed GFRP bars to seven years outdoor exposure with nearly no stress which is one of the few long-term research results. The V1 type GFRP bars with radius of 16mm were used to predict the long term tensile strength. The V1 type GFRP bars contained E-glass fibers embedded in a vinyl ester resin. These bars were made with external helical fiber wrapping and were coated with fine sand in the surface. The test temperature was room temperature 21.11℃. The diffusion coefficients are different under different environments for different types of GFRP bars. Trejo et al reported a range of diffusion coefficient for the different GFRP bars from 4.47×10-10 in2/sec (2.88×10-13 m2/sec) to 2.39×10-9 in2/sec (1.54×10-12 m2/sec), with a mean value of 1.38×10-9 in2/sec (8.9×10-13 m2/sec). The mean value was used for the modeling.

The historical observations and the approximate density function of unknown parameters Θ (λ, α, S_0, S) are shown in Fig. 1-2.

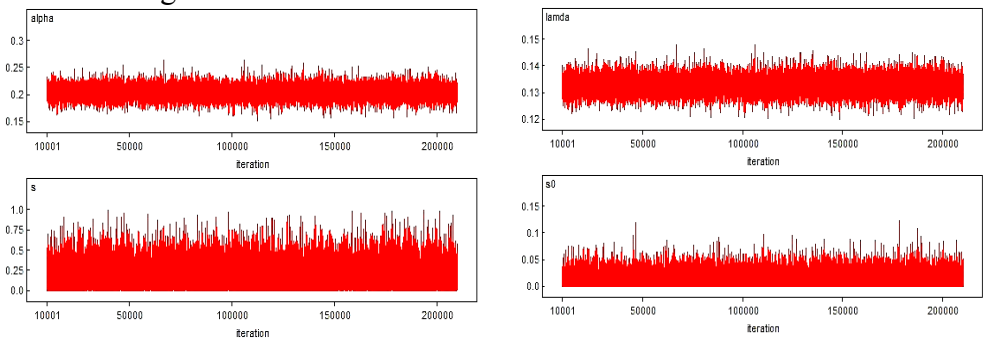

Fig. 1. The historical observations of unknown parameters

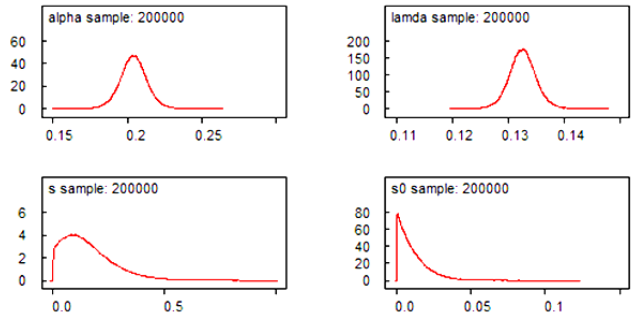

Fig. 2. The approximate density function of unknown parameters

The values of unknown parameters Θ (λ, α, S_0, S) were substituted into the prediction model equation (11), and the time t=7years=22903200 sec was set to obtain tensile strength σ_t=533.24MPa. From the literature (Trejo al 2009) the tensile strength mean value was 537.21MPa and standard deviation was 75.23 MPa after 7 years. The error of tensile strength retention after 7 years is 2.6% based on comparison between the test value and the predicted value under the same environment and materials. Therefore, the prediction model can reasonably predict the tensile strength of GFRP bars as an indicator of the durability after a long time.

Conclusions

The less information likelihood function method based on the results of previous studies was proposed in this paper. A simple and workable prediction model solution was presented which fit the development trend on basis of probability or reliability to set up structural design theory. The residual strength behavior of GFRP bars in concrete beams in environmental exposure of seven years was analyzed. Namely, the tensile strength values of the prior 150 weeks, almost 3 years, were used to set up the model, the tensile strength retention after 7 years' environmental exposure was predicted through the model. The results showed that the theoretical predictions and experimental data were close, which demonstrated that the theoretical prediction model and corresponding solution method was reasonable.

Keywords: RBFNN; IDA; isolated continuous girder bridge; fragility analysis

Abstract: To approximate the correlating mathematical relationship between many earthquake records' PGA and the responses of bridge structures with minimum efforts and without loss of accuracy, an artificial neural network-based method is proposed in combination with LHS and IDA method. This method is employed to conduct the seismic fragility analysis of RC isolated continuous girder bridge. To investigate the suitability of this approach, the results of the new approach are compared to those obtained by the Cloud method. The comparison shows that the new method is more efficient and reliable.

Introduction

Bridge structures are important hub structures of transportation lifeline engineering. The seismic fragility analysis of RC isolated continuous bridge is comparatively few, as a relatively new bridge type. Fragility curves are often used to express seismic fragility. The curves represent the conditional probability of each damage state's occurrence under different seismic intensities. When the seismic fragility analysis of bridge structures is carried out, the nonlinear time history analysis needs a large amount of calculation, thus the high consumption of computer work and time cost. In addition, the input of seismic earthquake intensities is often limited and fixed and cannot cover all the possible conditions. Former seismic fragility analyses of bridge structures ignored these influential factors.

ANN (Artificial Neural Network, ANN) is an important branch of artificial intelligence, which is able to simulate the structure and function of the human brain system and establish good the appropriate network, through scientific study finding the corresponding input and output mapping relationship [1]. Therefore, it has the ability of processing nonlinear and adaptive information, thus suitable for nonlinear reasoning and predictions in structural engineering. So far, dozens or even hundreds of different types of ANN have been proposed. This paper select RBFNN (Radial Basis Function Neural Network, RBFNN) to train the sample, test the network and predict the seismic response of bridge structures, because of its strength of function approximation ability, learning speed and the good generalization capability.

In view of this, this paper proposes the RBFNN-based seismic fragility analysis method for RC isolated continuous girder bridge. After the trained and tested sample points using RBFNN method are got, the approximation to response values of bridge structure under different PGA horizontal

seismic actions can be conducted, using intelligent reliability algorithms based on RBFNN, indirectly the real limit state equations of the bridge can be achieved. After the bridge seismic fragility curves are obtained, the results are compared to those obtained by the Cloud method.

RBFNN

Fundamentals of RBFNN

An RBFNN structure consists of the input layer, hidden layer and output layer, which is a three-layer feed-forward neural network [2]. The general activation function of the RBFNN hidden layer is Gaussian function, and the activation function of the output layer is completely linear function which can achieve the linear combination of the neurons in the hidden layer. It's crucial that the RBFNN hidden layer is designed appropriately. In the hidden layer the selection of the function center c_j, width b and weight w_j can fundamentally affect the ability of learning and prediction. To build and train a EBFNN, the core is to find a proper neural network mapping function to denote the relationship between input space and output space, which also means to design the parameters of the function center c_j, width b and weight w_j [3].

Realization of RBFNN

To start the RBFNN training the variable and function values of a number of sample points need to be known. Sample points consist of training sample points and test sample points which are used to train RBFNN and test the prediction ability of RBFNN respectively. This paper use Latin Hypercube Sampling (Latin hypercube sampling, LHS) as the sampling method. LHS was first proposed by McKay , and then was given a mathematical formulation by Stein. LHS is a good variance reduction technique and can serve as an alternative to the Monte Carlo method, which is widely applied in simulation, optimization and reliability calculation.

The procedure to realize RBFNN is as follows:

(a) non-guided learning. The parameters of each neuron in the hidden layer, such as c_j, σ_j and the weight between the hidden layer and input layer, are defined according to all input samples;

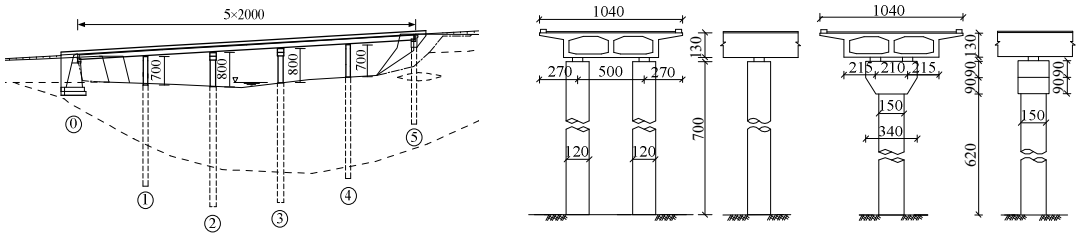
(b) guided learning. The weight between the hidden layer and output layer is defined based on the input sample data using the least square method. This paper employs the newrb function in matlab to establish, train and test RBFNN. The call of newrb function is as follows: net=newrb (X, T, GOAL,SPREAD,MN,DF) [4].

RBFNN-based seismic fragility analysis for RC isolated continuous girder bridge

Procedures.

(a) Use IDA analysis to provide enough random samples for FBFNN training and test;

(b) Approximate the relationship between some response values of the bridge and PGAs using RBFNN;



(c) Use RBFNN to predict the seismic response values under every PGA.

(d) Draw seismic fragility curves based on the data obtained through former steps using the Frequency method.

Introduction and formation of the bridge

The bridge this paper studied is on a second class highway located in western part of China. It's a RC isolated continuous bridge with five equal spans and 100-meter overall length. The bridge's

layouts and sections are plotted in Figs.1-(a) and 1-(b) respectively. The seismic isolation bearing LRB500 is used to collect the main beam and the top of the piers. For further information regarding the finite model, refer to Xiao Hong Long et al. [5].

(a) Elevation view (b) Cross-sections of box girder and pier

Fig.1 Elevation and cross-sections of the bridge

Probabilistic seismic demand analysis

(a) Considering uncertainties of earthquake ground motion. Based on Pacific Earthquake Engineering Research Center ground motion database, 100 natural ground motion records are selected correspondent to the site condition (second-class site) where the structure is located. The selected earthquakes are all far-field earthquakes, with the earthquake magnitude ranging from 5.5-8.0, PGA widely distributed, which also satisfy the site conditions demand.

(b) Considering uncertainties of structure. Taking the sensitivity of structure's seismic response to material parameter into consideration, the steel's yield strength f_y, the steel's elastic modulus E_s, the concrete's compressive strength f_c, the seismic isolation bearing's stiffness before yielding K_1, and the seismic isolation bearing's yielding shear force are selected as random variables. The random variables' distributions are shown in Table 1.

100 structure samples can be obtained through random sampling based on the LHS method, and each bridge sample matches one record of ground motion randomly. Each ground motion record includes deformation values of isolator bearings under 30 PGAs ranging from 0.02g to 1.0g uniformly.

Definition of damage states

Displacement ductility is used as piers' demand parameters, while a bearing's displacement based on the relative shear strain is isolation bearings' demand parameters. According to Liu [6] and Zhang [7], the definition of damage states is shown in Table 1.

TABLE 1SUMMARY OF DAMAGE INDEXES AND CORRESPONDING DAMAGE STATES FOR PIER COLUMNS AND BEARINGS

Bridge component	Basically intact	Slight	Moderate	Extensive	Collapse
1# pier column	$\mu_d \le 1$	$\mu_d > 1$	$\mu_d > 1.436$	$\mu_d > 2.302$	$\mu_d > 5.302$
2# pier column	$\mu_d \le 1$	$\mu_d > 1$	$\mu_d > 1.439$	$\mu_d > 2.361$	$\mu_d > 5.361$
isolation bearing[δ/mm]	$\delta \le 75$	$\delta > 75$	$\delta > 112.5$	$\delta > 150$	$\delta > 187.5$

RBFNN-based seismic fragility analysis

After the sample points (training samples and test samples, 5000 samples in longitudinal or lateral direction) are obtained, the building, training and test of RBFNN can be achieved using newrb function in matlab. Take 1# isolator bearing's deformation with No.1 bridge sample under No.54 ground motion as an example. Thirty deformation values are used as training samples under each PGA varying from 0.02g to 1g with the tolerance 0.04g. After RBFNN model is trained, the

deformation under these 20 PGAs (0.04g to 0.98g, tolerance 0.04g) can be predicted, thus the rest 50 PGAs (0.01g to 0.99g) can be predicted further. The data under 20 PGAs (0.04g to 0.98g) are used as the test samples, and the errors of training samples and test samples can be seen in Table3 and Table 4. This paper assumes that the pier's probability of failure is 0, so the seismic fragility of pier is not considered.

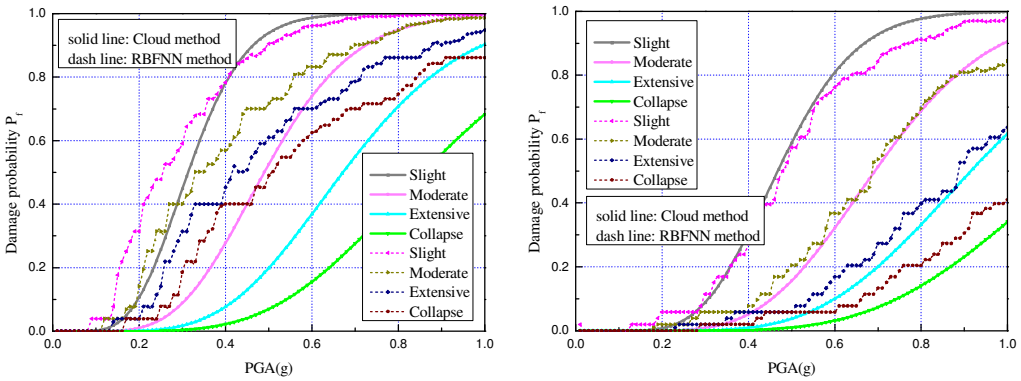
TABLE 3 DEFORMATION OF 1# ISOLATION BEARING DEFORMATIONS AND RBFNN TESTING RESULTS



Sample number	PGA [g]	Real value [m]	Predicted value [m]	Relative error [%]	Sample number	PGA [g]	Real value [m]	Predicted value [m]	Relative error [%]
1	0.04	0.0107	0.0099	-7.48	11	0.54	0.227	0.2268	-0.09
2	0.08	0.0217	0.0226	4.15	12	0.58	0.2485	0.2484	-0.04
3	0.14	0.0375	0.039	4.00	13	0.64	0.2808	0.2808	0.00
4	0.18	0.0529	0.0527	-0.38	14	0.68	0.3025	0.3024	-0.03
5	0.24	0.077	0.077	0.00	15	0.74	0.3349	0.3348	-0.03
…	…	…	…	…	…	…			
10	0.48	0.1948	0.1949	0.05	20	0.98	0.4639	0.4634	-0.11

Relative error= (predicted value-real value) / real value×100%.

It can be seen from Table 3 and Table 4 that the maximum absolute value of training samples' relative error is 2%,and the others are also quite small. The maximum absolute value of test samples' relative error is 7.48%, and its maximum value is under the PGA of 0.04g because RBFNN tends to have more errors at the edge (a possible sollution is to select more sample points at the edg), while the absolute value of other test samples' relative error is below 5%. It proves that RBFNN has a good prediction ability. The mean square error of the trained model is 4.35753e-005.

In accordance with the Freqency method [8], the sample points obtained by RBFNN can be directly used to make statistical analysis. The limit state function of the structure can be defined as follows: (a) slight damage: Z=D-0.075; (b) moderate damage: Z=D-0.1125; (c) extensive damage: Z=D-0.15; (d) collapse damage: Z=D-0.1875. D represents the deformation of the isolation bearing. After the training of RBFNN, totally 100 PGAs with 100 samples correspondent to each PGA can be obtained. According to the Frequency method, the sample number N_f of each damage state under each PGA can be counted, and then N_f is divided by the total sample number N_t, hence the

probability of failure corresponding to its damage state can be derived. In this paper, the value of N_t is 100. Based on the results of the matlab calculation, the comparison of seismic fragility curves by the SVM and Cloud method can be seen in Fig.3

(a) In the longitudinal direction (b) In the lateral direction

Fig.3 Fragility curves of bridge system

Conclusion

This paper conducts the seismic fragility analysis of the RC continuous girder bridge based on RBFNN, LHS and IDA method with the thinking of Frequency method. The comparison results of RBFNN and the Cloud method can draw the conclusions as follows.

(a) Compared to the proposed method, the Cloud method has smaller results in the longitudinal direction, and so is it with the situation in the lateral direction except for the results of slight damage. So the seismic fragility analysis of Cloud method is comparatively small.

(b) RBFNN-based seismic fragility analysis method for RC continuous girder bridges can efficiently save some computational work and the results are reliable.

Keywords: Optimization design; robust design; uncertain parameters; frequency constraint; Taylor's series

Abstract. The structural physical properties are often uncertain due to manufacture errors, measurement errors and other factors. Consequently, the vibration frequencies and corresponding eigenvectors are also uncertain. Robust design selects suitable design variables so that structural performance is insensitive to the various causes of variation without eliminating possible variations of variables. In practice robust design methods can be classified into probabilistic methods and non-probabilistic methods respectively. A new non-probabilistic robust design method based on the set theoretical convex method is presented in the present paper. The method not only inherits the advantages of existing non-stochastic methods, but also conquers the disadvantages of these methods.

Introduction

Modal analysis of structures plays an important role in structure design. However, due to the manufacturing errors, measurement errors and other factors, structural geometric properties and mechanical properties are usually uncertain. As a result, structural vibration frequency, i.e. eigenvalue, and corresponding eigenvector are also uncertain.

The structural dynamic optimization problems have been gradually focused on since the 1970s. Zarghamee [1], Lin [2], Wang [3] and Grandhi [4] conducted their research on the structural optimization design with constraint conditions having fundamental frequency or frequency restricted area. However, due to the presence of uncertain factors, classical optimization method cannot solve structural design problems effectively. Researchers propose some probabilistic optimization design methods on the basis of probability statistics. Rao [5] discussed probabilistic optimization of design parameters for a mechanical system under random vibration circumstances. Chen et al. [6] chose the mean values and standard derivations of stochastic design parameters as design variables, and converted the probabilistic optimization problem to certain optimization problem using probabilistic approaches, and solved the optimization design problem of MDOF linear torsion vibration system having uncertain parameters. Zang et al. [7] solved a two-DOF vibration damper design problem using the robust property of object functions in a review concerning the robust optimization, and decreased the vibration amplitude of the damper on condition that external excitation frequency and spring stiffness are uncertain.

In this paper, a non-probabilistic robust design method using both first-order and second-order Taylor's series to evaluate the intervals of eigenvalues and eigenvectors is presented on the basis of the parameter perturbation method and interval mathematics. Friswell's method [8] will be utilized to calculate the first-order and the second-order derivatives of eigenvalues and eigenvectors. A spatial 4-bar truss structure is optimized when material modulus and density are uncertain. Comparison among the non-probabilistic and probabilistic methods and the conventional optimization method is performed. Although the weight of the structure obtained from the non-probabilistic method is

heavier than the results generated by the probabilistic method and conventional method, the reliability and robustness of structures have been improved obviously.

Problem Statement

Generally undamped vibration analysis leads to an eigenproblem of the type

$$\boldsymbol{K}\boldsymbol{u} = \lambda \boldsymbol{M}\boldsymbol{u} . \tag{1}$$

where $\boldsymbol{K}$ and $\boldsymbol{M}$ are n-dimensional stiffness matrix and mass matrix respectively; λ is the eigenvalue which is the square of the frequency ω of free vibration, i.e. $\lambda = \omega^2$, and $\boldsymbol{u}$ is the corresponding n-dimensional eigenvector or the mode shape. The eigenvector is often normalized with the mass matrix and stiffness matrix such that

$$\boldsymbol{u}^T \boldsymbol{M}\boldsymbol{u} = 1 \ , \ \boldsymbol{u}^T \boldsymbol{K}\boldsymbol{u} = \lambda . \tag{2}$$

When structural parameters such as physical properties and geometric variables are considered, stiffness matrix $\boldsymbol{K}$, mass matrix $\boldsymbol{M}$, eigenvector $\boldsymbol{u}$ and eigenvalue λ are functions of the structural parameter vector $\boldsymbol{b}$, that is

$$\boldsymbol{K}(\boldsymbol{b})\boldsymbol{u}_i(\boldsymbol{b}) = \lambda_i(\boldsymbol{b})\boldsymbol{M}(\boldsymbol{b})\boldsymbol{u}_i(\boldsymbol{b}) . \tag{3}$$

Differentiating the ith-order eigenvalue in Eq. 3 with respect to the structural parameter b_k, and then expanding it we have

$$(\boldsymbol{K} - \lambda_i \boldsymbol{M})\frac{\partial \boldsymbol{u}_i}{\partial b_k} + \left(\frac{\partial \boldsymbol{K}}{\partial b_k} - \lambda_i \frac{\partial \boldsymbol{M}}{\partial b_k}\right)\boldsymbol{u}_i - \frac{\partial \lambda_i}{\partial b_k}\boldsymbol{M}\boldsymbol{u}_i = 0 . \tag{4}$$

Premultiplying Eq. 4 by $\boldsymbol{u}_i^T$, rearranging and using mass normalization of the ith eigenvector give the first-order derivative of the ith eigenvalue as

$$\frac{\partial \lambda_i}{\partial b_k} = \boldsymbol{u}_i^T \left(\frac{\partial \boldsymbol{K}}{\partial b_k} - \lambda_i \frac{\partial \boldsymbol{M}}{\partial b_k}\right)\boldsymbol{u}_i . \tag{5}$$

In order to calculate the first-order derivatives of eigenvectors, we suppose

$$\boldsymbol{G}_i = \boldsymbol{K} - \lambda_i \boldsymbol{M} \quad , \quad \boldsymbol{p}_{ik} = \frac{\partial \lambda_i}{\partial b_k}\boldsymbol{M}\boldsymbol{u}_i - \left(\frac{\partial \boldsymbol{K}}{\partial b_k} - \lambda_i \frac{\partial \boldsymbol{M}}{\partial b_k}\right)\boldsymbol{u}_i . \tag{6}$$

Thus, from Eq. 4, by making some arrangements, we have

$$\boldsymbol{G}_i \frac{\partial \boldsymbol{u}_i}{\partial b_k} = \boldsymbol{p}_{ik} . \tag{7}$$

Obviously, the first-order derivatives of eigenvectors cannot directly be calculated from Eq. 7 since $\boldsymbol{G}_i = \boldsymbol{K} - \lambda_i \boldsymbol{M}$ is singular with rank n-1. To overcome the difficulty, Nelson [9] proposed that the derivatives be written in the following form

$$\frac{\partial \boldsymbol{u}_i}{\partial b_k} = \sum_{\substack{j=1 \\ j \neq i}}^{n} c_{jk}\boldsymbol{u}_j + c_{ik}\boldsymbol{u}_i = \boldsymbol{v}_{ik} + c_{ik}\boldsymbol{u}_i . \tag{8}$$

where $\boldsymbol{v}_{ik}$ and c_{ik} are vector and scalar respectively. Thus, in terms of vector $\boldsymbol{v}_{ik}$, Eq. 7 becomes

$$\boldsymbol{G}_i \boldsymbol{v}_{ik} = \boldsymbol{p}_{ik} . \tag{9}$$

where vector $\boldsymbol{v}_{ik}$ is not unique. If all the eigenvectors are included in the sum, Eq. 8 is exact. For most problems it is not practical to calculate all the eigenvectors, so that only a few of the eigenvectors associated with the lowest eigenvalues are included. To produce a unique vector $\boldsymbol{v}_{ik}$, Nelson proposed that *m*th element of $\boldsymbol{v}_{ik}$, which corresponds to the element of highest magnitude in the eigenvector $\boldsymbol{u}_i$, be set to zero. The remaining *n*-1 elements can be obtained from Eqs. 7 and 8. We can solve the following equivalent problem to retain the sparse nature of the problem

$$\begin{pmatrix} (\boldsymbol{G}_i)_{11} & 0 & (\boldsymbol{G}_i)_{13} \\ 0 & 1 & 0 \\ (\boldsymbol{G}_i)_{31} & 0 & (\boldsymbol{G}_i)_{33} \end{pmatrix} v_{ik} = \begin{pmatrix} (\boldsymbol{p}_{ik})_1 \\ 0 \\ (\boldsymbol{p}_{ik})_3 \end{pmatrix}. \tag{10}$$

in which the *m*th row and column of the matrix have been replaced by the corresponding row and column from the identity matrix and the *m*th component of the vector $\boldsymbol{p}_{ik}$ has been set to zero. This will produce the zero required in the *m*th component of and also yield a full-rank matrix in Eq. 10.

Once $\boldsymbol{v}_{ik}$ has uniquely been obtained from Eq. 10, the scalar c_{ik} is found by using the derivative of the mass normalization condition in Eq. 2. Differentiating the *i*th-order eigenvector in Eq. 2 with respect to the structural parameter b_k, gives

$$\boldsymbol{u}_i^T \frac{\partial \boldsymbol{M}}{\partial b_k} \boldsymbol{u}_i + 2\boldsymbol{u}_i^T \boldsymbol{M} \frac{\partial \boldsymbol{u}_i}{\partial b_k} = 0. \tag{11}$$

Since all the terms are scalar. Substituting the expression for the eigenvector derivative Eq. 6 into Eq. 12 and using mass normalization condition Eq. 2 provide the solution for c_{ik} as

$$c_{ik} = -\boldsymbol{u}_i^T \boldsymbol{M} \boldsymbol{v}_{ik} - \frac{1}{2} \boldsymbol{u}_i^T \frac{\partial \boldsymbol{M}}{\partial b_k} \boldsymbol{u}_i. \tag{12}$$

Numerical Example

A 4-bar spatial truss structure shown in Fig. 2 is used to demonstrate the present method. The nominal values of structural parameters used are elastic modulus of material E=70 GPa and density ρ=2700 kg/m^3. It is assumed that elastic modulus E and diameter ρ involving perturbations in manufacturing process are uncertain-but-bounded parameters. The variations of each parameter are ΔE=10 MPa and $\Delta\rho$=27 kg/m^3, which can be rewritten as E^I=[E^0- ΔE, E^0+ ΔE] and ρ^I=[ρ^0 - $\Delta\rho$, $\rho^0 + \Delta\rho$] using interval analysis [11].

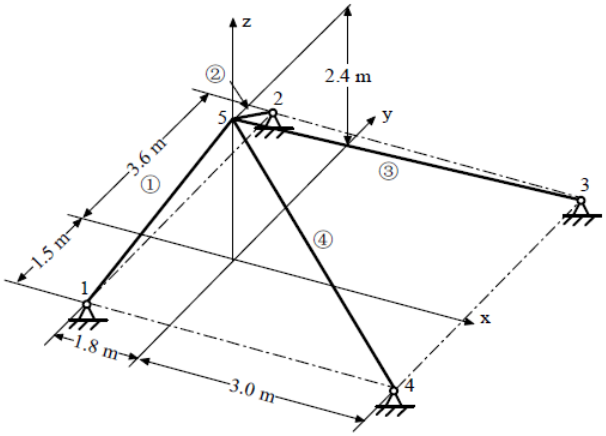

Fig. 2 4-bar spatial truss structure

Assume the lower and upper bounds of the bar cross-sectional area are 6.45E-5 m^2 and 6.45E-3 m^2 respectively, the structural frequency restricted area [$\underline{\omega}$, $\overline{\omega}$]=[110, 180]Hz. According to the approach for determining the concerning frequency mentioned in previous section, the first-order and second-order frequency of the structure are concerning frequencies, i.e. i=1, j=2. The equation of probabilistic and non-probabilistic robust design are given in Eq. 13 and Eq. 14 respectively.

$$\min \quad w \equiv \rho \sum_{i=1}^{4} L_i A_i; \ \text{s.t.} \quad \mu_{g_j} + z_{\alpha_j} \sigma_{g_j} \le 0 \ \ (j = 1,2); \quad A_i^L \le A_i \le A_i^U \ \ (i = 1,2,3,4). \tag{13}$$

where $\mu_{g_1} = \omega_1^2\left(\boldsymbol{A}^0\right) - \underline{\omega}^2$, $\mu_{g_2} = -\omega_2^2\left(\boldsymbol{A}^0\right) + \overline{\omega}^2$, $\sigma_{g_j} = \sqrt{\left(\frac{\partial \omega_j^2}{\partial E}\right)^2 \sigma_E^2 + \left(\frac{\partial \omega_j^2}{\partial \rho}\right)^2 \sigma_\rho^2}$, ($j$=1,2).

$$\begin{aligned} &\min \ w \equiv \rho \sum_{i=1}^{4} L_i A_i \\ &\text{s.t.} \quad g_1 = \omega_1^2\left(\boldsymbol{A}\right) - \underline{\omega}^2 + \Delta g_1 \le 0; \ g_2 = -\omega_2^2\left(\boldsymbol{A}\right) + \overline{\omega}^2 + \Delta g_2 \le 0; \ A_i^L \le A_i \le A_i^U \quad (i = 1,2,3,4) \end{aligned} \tag{14}$$

where $\Delta g_j = \sqrt{2}\sqrt{\left(\frac{\partial \omega_j^2}{\partial E}\right)^2 \left(\Delta E\right)^2 + \left(\frac{\partial \omega_j^2}{\partial \rho}\right)^2 \left(\Delta \rho\right)^2}$ (j=1,2).

Numerical Results for the structure using optimization design methods mentioned before show that, when the elastic modulus and density of material varies for 0.0143% and 1% respectively, the structural weight generated by non-probabilistic robust optimization is heavier by 214.5% than that obtained by traditional optimization method，while the results of probabilistic optimization with reliability 97.5％ and 99.87% are heavier than the result of traditional optimization method by 115.6% and 166.2%. The structural fundamental frequency derived from non-probabilistic method is smaller than that derived from the traditional method by 5.46%. The results of probabilistic method is smaller than the result of the traditional method by 3.71% and 4.62% respectively.

The variance amplitude of the structure weight using different optimization methods is large. Minor varieties of structural parameters, i.e. elastic modulus and density of the material lead to great difference among the structural design results. We can find the reason that, on one hand, the frequency constraints are overall constrains so that any change in structural parameters will affect the optimization result. On the other hand, the structural frequencies are highly non-linear function of the parameters. Define uncertain degree $\beta \in [0, 1]$ as the scale of the variation of uncertain parameters. The weight of the 4-bar truss with respect to β derived from the non-probabilistic and probabilistic methods are shown in Fig.3. The starting point of the curve is the structural weight derived from traditional method when β=0. When β is small, the increasing range of the structural weight is small, which means the result is less influenced by the varieties of the uncertain parameters. When β increased gradually, the increasing range of the structural weight becomes larger, and the trend is the most obvious in the non-probabilistic method. The same trend can be seen in the probabilistic method.

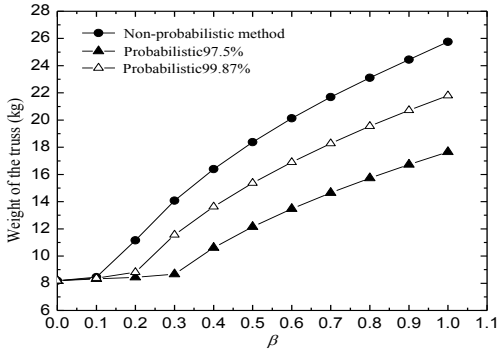

Fig.3 Weight of 4-bar truss with respect to β

Since both non-probabilistic and probabilistic methods need to calculate the first-order derivatives to the uncertain parameters, and the feasible region also depends on the derivatives, the relationship between the first-order derivatives to uncertain parameters and β needs to be considered. The first-order derivatives of the structural fundamental frequency with respect to β are shown in Fig. 4. While β is small such as $\beta \leqslant 0.1$, the value of the derivatives changes slowly, and the value changes

remarkably when β is getting larger. We can see that the value of the derivatives derived from the non-probabilistic method is smaller than that derived from the probabilistic method. The result means the fundamental frequency of non-probabilistic method is the least affected by uncertain parameters.

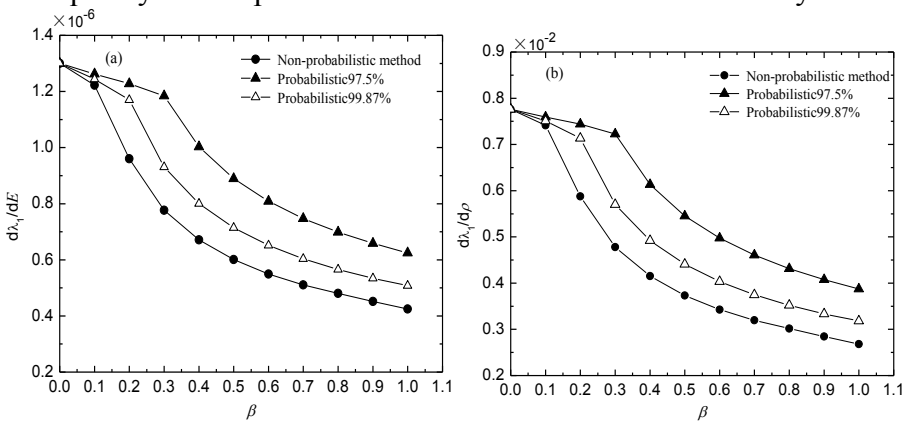

Fig.4 First-order derivatives of fundamental frequency to structural parameters with respect to β: (a) elastic modulus; (b) density

Conclusions

A non-probabilistic robust design method is presented in this paper. When uncertain structural parameters vary in a certain range, the vibration frequencies of the structure will have fluctuation around the nominal values. A numerical example of a spatial 4-bar truss structure with uncertain elastic modulus and density is utilized to demonstrate the method. Comparison among the non-probabilistic, probabilistic methods and the conventional optimization method is performed. Although the weight of the structure obtained from the non-probabilistic method is heavier than the results generated by the probabilistic method and conventional method, the reliability and robustness of structures have been improved obviously.

Keywords: w/c, BEI, capillary porosity, age, function fitting

Abstract. In order to detect the influence of age on the experiment that use scanning electron microscopy (SEM) to determinate the original water-cement ratio (w/c) of hardened concrete, a series of concrete mixes are tested. Experimental results show that early ages do have an effect on the water-cement ratio of hardened concrete that determined from scanning electron microscopy, this effect will decrease while age increases. The relationship between capillary porosity, w/c and age is analyzed and a calculation equation is given.

Introduction

Water-cement ratio is the primary factor of concrete strength, a direct impact on the properties of concrete and the economic effect, whether the w/c is too large or too small, it will be an adverse effect on the performance of concrete [1]. Internal pore will be formed in the concrete during fresh concrete in the process of hardening [2], different water-cement ratio of hardened concrete result in different final internal porosity, literature [3] pointed out that the porosity of concrete is mainly decided by w/c. The greater the w/c, the greater the capillary porosity of concrete. Even if the w/c of hardened concrete is the same, its internal capillary porosity is not the same in different age, with the growth of the age，its capillary porosity is also increasing, and in different age stages of growth rate is not the same, This brought a great disturbance on the results of scanning electron microscopy test, therefore it is necessary to study the age influence on the results from scanning electron microscopy to determine the original w/c hardened concrete.

Recently, the main theoretical method that determines the water-cement ratio of hardened concrete is: Firstly, sanding the small cubic concrete section , then inset the cubic concrete into epoxyresin with Vacuum Mosaic instrument[4], capillary porosity can be completely filled with epoxy resin, after drying and polishing, pore in the scanning electron microscopy (SEM) to carry on the back scattering model (BEI) [5] ,the shown in the photo is black. However, the other solid phase is bright color, through the image analysis procedure，the capillary porosity of concrete can be quantitatively calculated. Then try to establish a function relationship and the function curve between w/c and capillary porosity. However, in the actual situation, even if the same w/c of hardened concrete, its internal capillary porosity is not the same along with the age which is not at

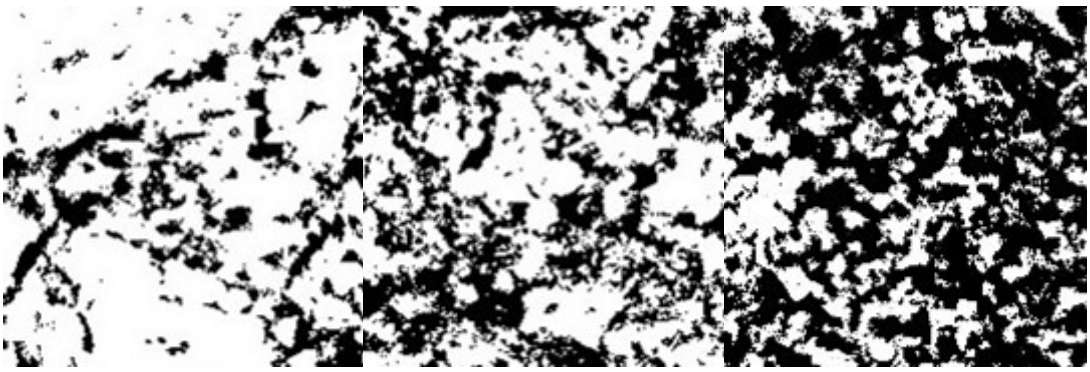
the same time, it brings great influence on the accuracy of the test results. Literature [5] does not mention the age factor upon the result of the experiment, becauseof the difference on the domestic and foreign cement manufacturing
technique, chemical species, content and quality, the results of same experiment at home and abroad may also have big difference.

This study is based on different age of hardened concrete experiment research to determine the age influence on scanning electron microscopy that determines the original w/c of hardening concrete and try to estimate a function relationship among capillary porosity, w/c and date . This article has carried on the experiment, provides the theoretical methods and technical support for such research.

Materials

Use standard sand and artificial stone（the particle size of 10 to 40 mm），which is the raw materials of hardened concrete ，use benchmark cement as the cement of concrete ，The chemical composition is shown in table 1:

Table 1Chemical composition of benchmark cement



SiO_2	Al_2O_3	Fe_2O_3	CaO	MgO	SO_3
21.96	4.73	3.68	65.3	2.59	0.3
NaO_{eq}	f-CaO	C_3S	C_2S	C_3A	C_4AF
0.56	0.9	57.4	20.3	6.32	11.19

Experimental Methods

Known as the preparation of w/c of hardened concrete :0.3,0.35,0.4,0.45,0.5, removed 3 in its reach 3d, 7d, 28d and 90d of the age respectively, the hardened concrete is cut into a cube of side length which is not more than 1cm with concrete cutting machines, after sanding on concrete sections in small cubes resin saturated with resin inlay instrument , the pores may be completely filled with epoxy resin ,after drying and polishing, the capillary in the resin saturated backscattered SEM photograph mode are displayed as black ,while other solid phases are bright. By image analysis procedures, the capillary porosity of concrete can be quantitatively calculated. Next is to gain data about capillary porosity of different ages to get function fitting, Check whether can get more suitable function ,so as to test the effect of the age for scanning electron microscopy to determine the original w/c of the hardened concrete . If the influence exists，try to build a function relationship among porosity rate, w/c and date.

Results and Discussion

Figure 2 is the picture of hardened concrete section that obtained from the experiment scheme, the following w/c is 0.3, 0.4, 0.5, it can be seen that the greater water-cement ratio, the greater porosity of the section.

w/c=0.3 w/c=0.4 w/c=0.5

Fig2. Photos of hardened concrete section whose w/c are 0.3, 0.4 and 0.5

Figure 3 is about the images of the hardened concrete whose w/c is 0.4 in 3d, 7d, 28d and 90d.

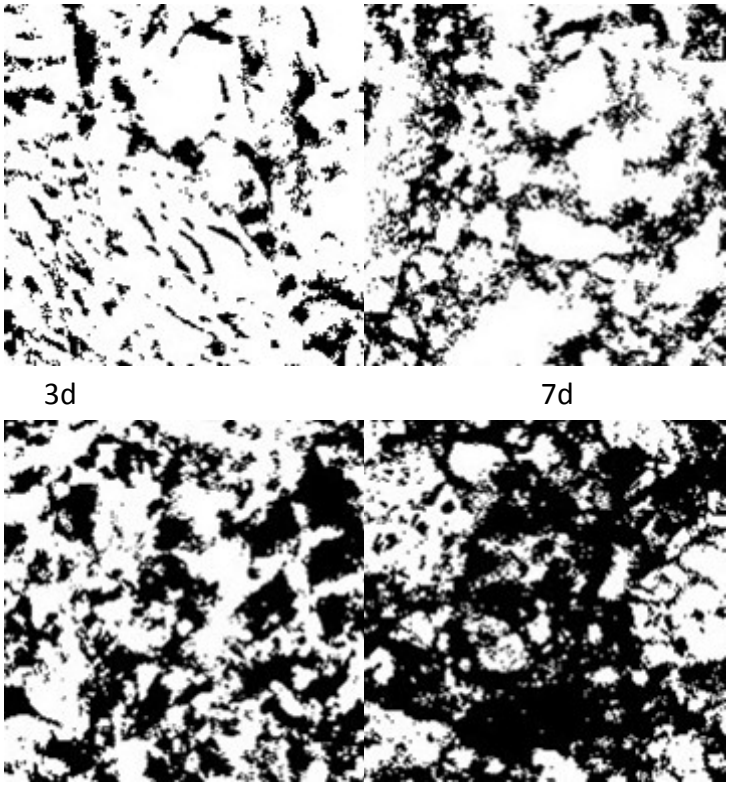


Fig3. Images of the hardened concrete whose w/c is 0.4 in 3d,7d,28d and 90d

Using the image pro plus 6.0 software to analyze the images, three groups of capillary porosity can be got ， the average is in table 2.

Table 2 Capillary porosity under different w/c and ages

age \ w/c	0.3	0.35	0.4	0.45	0.5
3d	27.7	33.6	33.9	38.6	43.5
7d	37.4	39.4	41.3	48.7	52.3
28d	39.2	44.6	49.8	50.1	57.3
90d	41.2	45.8	49.3	52.6	57.9

Take the average of three groups of data to make function fitting, the relationship between w/c of hardened concrete in different ages and the capillary porosity is shown in figure 4.

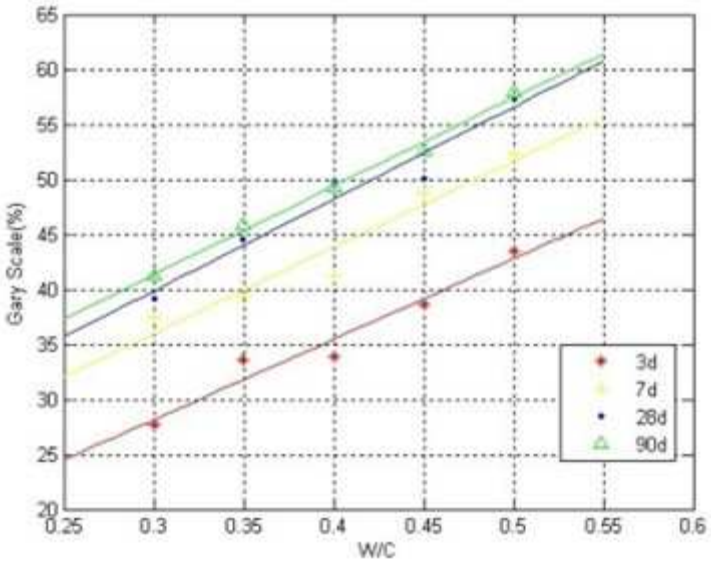

Fig 4 Relationship between w/c and the capillary porosity in different ages

Analytic functions corresponding to the four curves in Fig 4 are：

3d：y=73.200x +6.180 (1)

7d：y=78.200x+12.540 (2)

28d：y=83.400x+14.840 (3)

90d：y=80.400x+17.200 (4)

Formula (1)-(4)suggests that the age did affect on the result from scanning electron microscopy that determines the original w/c of hardened concrete. Using the mat lab software to establish the function relationship between the capillary porosity, w/c and the age , their function relationship is as formula (5)：

$$y=75.6062x_1-328.8918/x_2^3+17.3131 \quad (5)$$

Where y is the capillary porosity, x1 is w/c, x2 is the age of the concrete.

If the types of raw material of this experiment change , it may need to use this test method to simulation analysis again.

Conclusion

Known from the analysis of the above test, early ages do have an effect on the w/c ratio of hardened concrete that determined from scanning electron microscopy , with the increase of age, function fitting is better; with the increase of age ,the results of scanning electron microscopy that determines the w/c of hardened are higher accurate, and relation among capillary porosity ,w/c ratio and ages can be synthesized to a function form, so it is suggested to use a long age sample in the engineering practice .

Keywords: Empty holes; Damping effect; Blasting vibration; Influencing factors

Abstract. The two-dimensional discrete element program (UDEC) is applied to simulate the damping effect of empty holes on blasting vibration. The results show that the peak particle velocity of monitoring point on the condition that there are empty holes between monitoring point and blast hole is less than that without empty holes. The factors which have impact on cushioning effect, such as the depth of empty hole, the diameter of empty hole, the distance between empty hole and blast hole and the rows of empty hole, are investigated numerically. It is found that the depth of empty hole has dominated influence on the damping effect and the damping effect on blasting vibration strengthens with the increment of the depth. The diameter of empty hole and the distance between empty hole and blast hole have slight influence on the damping effect. The increment of rows of empty hole can enhance the damping effect on blasting vibration as well. The results in the present study may provide a reference for the application of empty hole to reduce the blasting vibration in practical engineering.

Introduction

In foundation and slope blasting excavation, the stress waves induced by explosion can have a significant influence upon the engineering safety and even destroy the constructions. Measures should be taken to reduce the stress waves to protect the constructions and keep the engineering safe. Presplitting blasting can be used to reduce the damage on the reserved rock mass and improve the stability of slope in the excavation of rock slope[1]. In foundation excavation of a nuclear power station, the blasting vibration should be controlled strictly in order to ensure the safety of bedrock, buildings and structures around the blasting zone. The empty hole is adopted to reduce the blasting vibration[2]. The in-situ blasting tests reveal that shock absorption holes can reduce the blasting vibration and the peak particle velocity of monitoring points decreases obviously. The excavation of damping slots is an effective measure to reduce the blasting seismic effect. The damping effect of vibration-isolating ditches and influencing factors were researched by numerical simulation [3,4,5]. The length and depth of vibration-isolating slot have a significant influence upon the damping effect.

In this research, UDEC is employed to simulate the damping effect of empty holes on the blasting vibration[6,7]. By comparing the peak particle velocity of the same monitoring point on the condition that there are empty holes between monitoring point and blast hole with that without empty holes, it is revealed that the empty holes can reduce the blasting vibration obviously. The distance between empty hole and blast hole, the depth and diameter of empty hole are changed to study the influencing factors on vibration-isolating effect. The impact of rows of empty hole on vibration-isolating effect is investigated as well by comparison.

Numerical Model

The numerical model is shown in Fig.1. The air in the empty hole can connect with the atmosphere and the hole is shallow, so the effect of air on the blasting vibration is neglected in this study. Physico-mechanical parameters of rock material are shown in table 1.

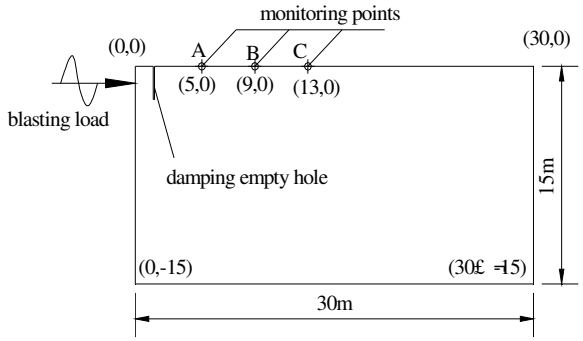

Fig.1 Numerical model

Table 1 Properties of rock material

Property	Value
Density[kg/m^3]	2606
Young's Modulus[GPa]	52.77
Poisson's Ratio	0.28
Cohesion[MPa]	26.83
Friction angle[°]	43.37

Two stages are involved in the UDEC modeling: (a) static modeling to determine the pre-existing stress in the rock mass before the explosion, and, (b) dynamic modeling to investigate the rock mass response due to the explosion [7]. Sine velocity waves are adopted to simulate the blasting load that the peak value is 5cm/s, the frequency is 30Hz, and the duration is 0.1s. The time history of velocity is translated to time history of stress to be the explosion input. To reduce the influence of the reflections of blasting vibration, viscous boundaries are employed.

The peak particle velocity (PPV) is the most appropriate motion parameter to correlate damage. It can be related directly to peak transient stress in the ground wave, and the second power of velocity is related to dynamic strain energy [8]. Three measurement points are placed at 5, 9 and 13m on the x-axis to record the peak particle velocity of the rock mass. A large number of numerical simulations are conducted by changing the model parameters and a lot of PPVs are obtained from the modeling.

Numerical Results

The Damping Effect of Empty Hole

As it is shown in Fig.2, the peak particle velocity of the same monitoring point on the condition that there are empty holes between monitoring point and blast hole decreases evidently when compared with that without empty holes. The horizontal peak particle velocities of monitoring point A, B, C without damping empty hole are 3.31cm/s,2.22cm/s,
1.53cm/s and they are only 1.99cm/s,1.47cm/s,1.02cm/s with damping empty hole, decreasing 39.9%,33.9%, 33.3%, respectively . The results show that the empty hole can have damping effect on the blasting vibration.

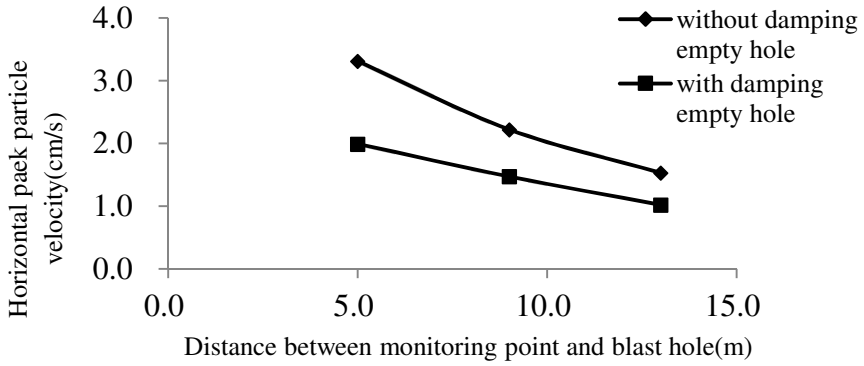

Fig.2 Comparison of horizontal peak particle velocity

The Influence of the Depth of Empty Hole on Damping Effect

Keeping the distance between empty hole and blast hole and the diameter of empty hole unchanged, the depth of empty hole is changed to study the influence of the depth on damping effect.

TABLE 2 PEAK PARTICLE VELOCITY AND DAMPING COEFFICIENT OF MONITORING POINT A WITH DIFFERENT DEPTH EMPTY HOLE

Depth of damping empty hole[m]	0.00	0.50	0.80	1.00	1.20	1.50	1.80	2.00	2.20	2.50	3.00
Horizontal peak particle velocity[cm/s]	3.31	2.76	2.37	1.99	1.61	1.13	0.74	0.56	0.42	0.34	0.33
Vertical peak particle velocity[cm/s]	4.24	4.20	4.07	3.35	2.17	1.14	0.35	0.37	0.38	0.35	0.35
Horizontal damping coefficient	/	0.17	0.28	0.40	0.51	0.66	0.78	0.83	0.87	0.90	0.90
Vertical damping coefficient	/	0.01	0.04	0.21	0.49	0.73	0.92	0.91	0.91	0.92	0.92

Remarks: The depth of blast hole is 2m.

Damping coefficient is defined as

$$\eta = \frac{v_1 - v_2}{v_1} \quad . \tag{1}$$

where v_1 is the peak particle velocity of monitoring point on the condition that there is no empty hole between blast hole and monitoring point, v_2 is the peak particle velocity of monitoring point on the condition that there is empty hole between blast hole and monitoring point.

The peak particle velocity and damping coefficient of monitoring point A with different depth empty hole are listed in table 2. When the depth of empty hole is less than 2.2m, it is shown in Fig.3 that the peak particle velocity decreases obviously with the increment of the depth of empty hole; the peak particle velocity almost keep constant with the increment of the depth of empty hole when it is more than 2.2m. It has the similar law as it is shown in Fig.4. The damping coefficient increases evidently with the increment of the depth of empty hole when it is less than 2.2m and nearly maintain unchanged when it is more than 2.2m. It is proposed that the reasonable depth of damping empty hole is 2.2m.

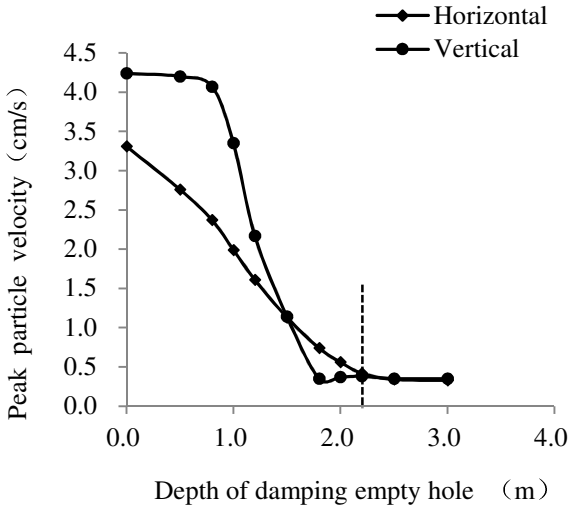

Fig.3 The relationship curves between peak particle velocity and depth of damping empty hole

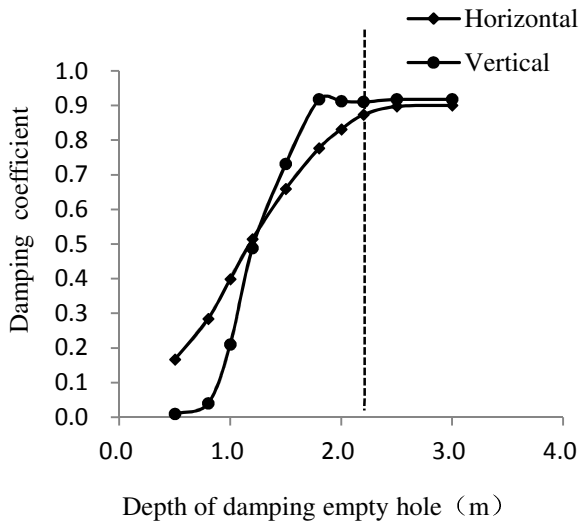

Fig.4 The relationship curves between damping coefficient and depth of damping empty hole

The Influence of the Diameter of Empty Hole on Damping Effect

Keeping the distance between empty hole and blast hole and the depth of empty hole constant, the diameter of empty hole is changed to study the influence of the diameter on damping effect. It is presented in Fig.5 that the horizontal damping coefficient almost keeps unchanged and the vertical damping coefficients fluctuate slightly with the increment of the diameter of empty hole.

The diameter of damping empty hole has slight impact on the damping effect.

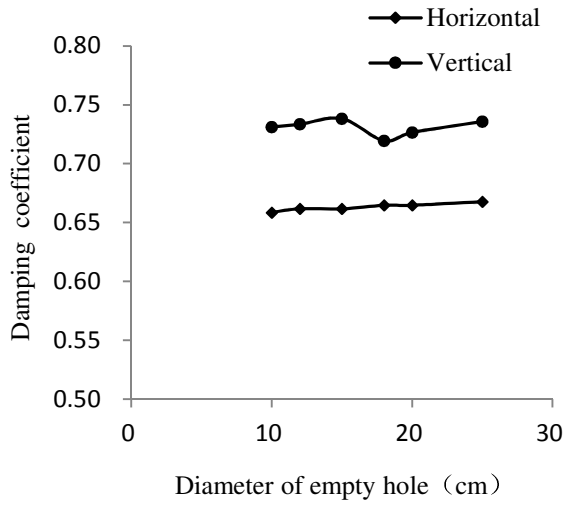

Fig.5 The relationship curves between the damping coefficient of monitoring point A and the diameter of empty hole

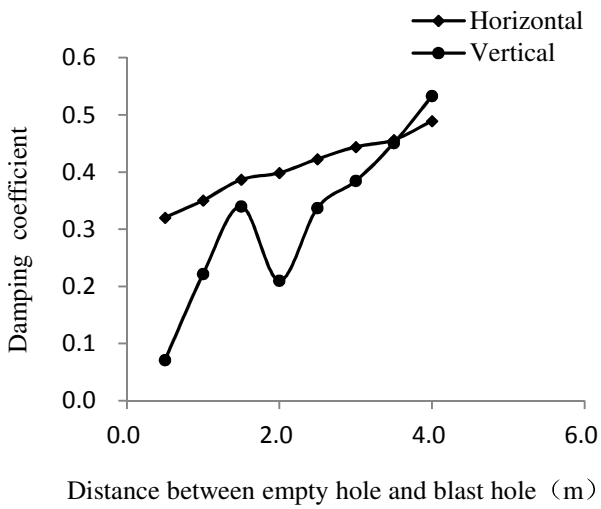

Fig.6 The relationship curves between the damping coefficient of monitoring point A and the distance between empty hole and blast hole

The Influence of the Distance between Empty Hole and Blast Hole on Damping Effect

Maintaining the depth and diameter of empty hole unchanged, the distance between empty hole and blast hole is changed to study the distance between empty hole and blast hole on damping effect.

The damping coefficient will increase with the increment of the distance between empty hole and blast hole on the whole as it is shown in Fig.6. The horizontal damping coefficient almost increases equably from 0.32 to 0.49, and the vertical damping coefficient increases inconsistently from 0.07 to 0.53 and fluctuates on the local scale.

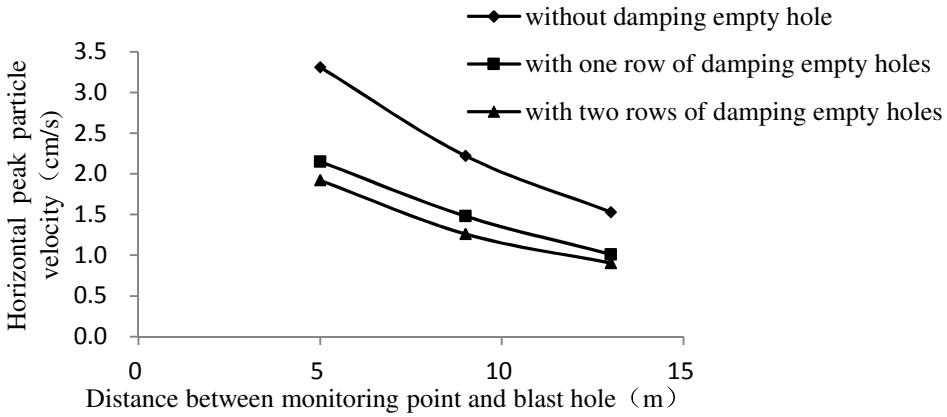

Fig.7 Horizontal peak particle velocity of monitoring point A, B, C with different rows of empty holes

The Influence of Rows of Empty Hole on Damping Effect

With the rows of empty holes increasing, the horizontal peak particle velocity decreases. As it is shown in Fig.7, the horizontal peak particle vibration velocity of monitoring point A is 3.31cm/s without damping empty hole and it is 2.15cm/s, 1.92cm/s with one row and two rows of damping empty hole, respectively. The peak particle velocity of monitoring point decreases with the increment of rows of empty hole, and the rate of decrease becomes slight gradually.

Summary

UDEC is employed to simulate the damping effect of empty holes on blasting vibration and the factors which have impact upon the damping effect are proposed. Some conclusions are reached as follows:

1. By comparing the peak particle velocity of the same monitoring point on the condition that there are empty holes between monitoring point and blast hole with that without empty holes, it is revealed that the empty holes can reduce the blasting vibration obviously. The empty holes can increase the propagation path and consume more energy of blasting waves, so the blasting vibration will decrease when passing through the empty holes.

2. The depth of empty hole has dominating influence upon the damping effect and the damping effect enhances with the increment of the depth of the empty hole. When the depth of empty hole is more than the depth of blast hole, the increment of damping coefficient is very slight. It is proposed that the depth of damping empty hole is 1.1～1.2 H, and H is the depth of blast hole.

3. The diameter of empty hole has slight influence on the damping effect and the damping coefficient almost maintain unchanged with the increment of the diameter of empty hole. The damping coefficient increases with the increment of the distance between empty hole and blast holes, and the increment of damping coefficient is much less than that caused by the increment of the depth of empty hole.

4. The increment of rows of empty hole strengthens the damping effect, and the rate of increasing becomes slight gradually. It is proposed that the rows of damping empty hole should be 2～3. Furthermore, the damping empty holes can be filled with vibration-absorptive material to have better damping effect in practical engineering.

Keywords: DeST-h, energy consumption, economical insulation layer residential building

Abstract: Based on the comparison of external wall with different insulation thicknesses and without insulation, residential buildings energy consumption was simulated by using DeST-h in Lanzhou. The effects of external wall insulation on building energy consumption were analyzed. The result shows that the total annual load can be reduced to 42% ~ 72% with the insulation thicknesses vary from 10mm to 80mm. But With the increase of the thickness of the insulation layer, the amount of fluctuation of building load reduces gradually. The insulation layer is thicker the energy saving effect is more distinct and there is should be the thickness is the most economical thickness. So the economic insulation thickness is determined as 40mm by using a life-cycle cost analysis.

Introduction

Since Design standard for energy efficiency of residential buildings in severe cold and cold zones was promulgated and implemented, The 65% energy-saving design standards has been implemented for residential buildings in Lanzhou. This put forward higher requirements of thermal performance standards for residential building envelopes. Reasonable residential building must ensure that the room is not only comfortable but also is energy - efficient. Residential building energy conservation is an important part of building energy saving, energy consumption ratio of residential building has increased year by year

Factors affecting the energy consumption are the building shape coefficient, retaining structure, natural ventilation and natural lighting levels, and the effect of the enclosure structure on energy consumption is the influence of maximum. In order to analyze energy consumption of Exterior wall of residential buildings quantitatively in Lanzhou, the energy consumption simulation software DeST-h [1] was used to simulate heating and air conditioning load. Annual total energy consumption rate was showed by comparing the different thickness of thermal insulation layer of wall. The economic insulation thickness was determined by using a life-cycle cost analysis method.

Construction survey and Establishment of model building

Taking a residential building in Lanzhou city as the simulation object, the area of residential building is 2520 square meters, shape coefficient is 0.342, and comprehensive window wall ratio is 0.16, the building has six floors, it is 2.9 meters high, the top floor is 3 meters high. Building toward the southern and Northern, the building model of plane and DeST geometry model as shown in Fig. 1, Fig. 2, structure and heat transfer coefficient of each part of retaining structure is shown in Table 1. The main part of the external wall insulation thickness is 200 reinforced concrete wall, insulation material are made of extruded polystyrene board [2]

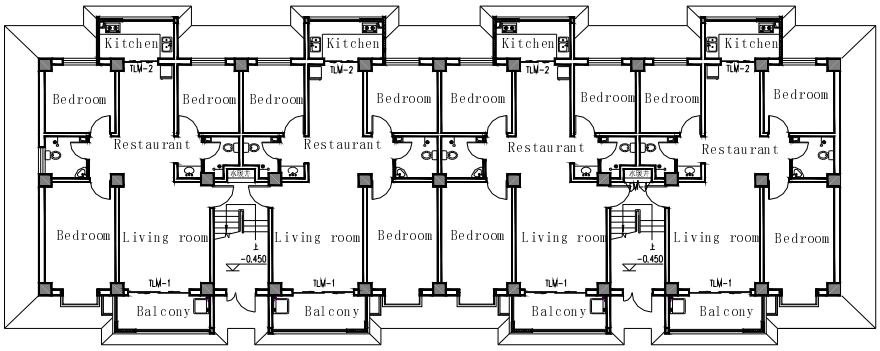

Fig. 1 Architecture model of plan

TABLE 1. THE THERMAL PHYSICAL PARAMETERS OF STRUCTURE

Category	Component	Heat transfer coefficient
Exterior wall	Cement mortar(20mm) +XPS(25mm)+ Cement mortar(20mm)+Reinforced concrete(200mm)	0.83
Inner wall	Cement mortar(20mm)＋Ceramist concrete(180mm)＋Cement mortar(20mm)	1.52
Roof	Cement mortar(20mm)＋XPS(55mm)+ Cement mortar(20mm)+Cement cinder(30mm)＋Reinforced concrete(150mm)＋Cement mortar(25mm)	0.34
Floor	Cement mortar(25mm)＋Reinforced concrete(80mm)＋Cement mortar(20mm)	3.05
Exterior window	Inert gas + Low-E coated hollow	2.0(SC＝0.56)

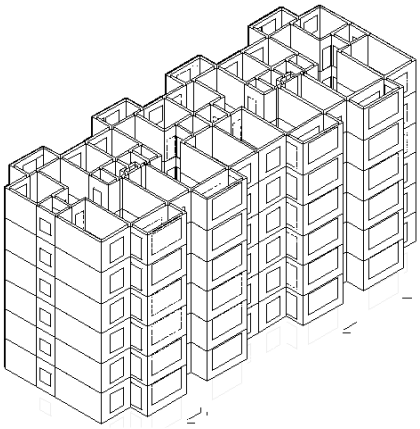

Fig. 2 DeST building model

Simulation results analysis

Calculation parameters of indoor was stetted according to Design standard for energy efficiency of residential buildings in severe cold and cold zones and Design code for heating ventilation and air conditioning of civil buildings . The meteorological data used in the simulation are come from typical meteorological year data issued by Technology Department of Tsinghai University and Meteorological Information Center Meteorological data of China Meteorological Administration. Lanzhou's 8760 hourly meteorological parameters were calculated by using DeST-h as shown in Fig. 3.

The room functions of residential building is simplified as the bedroom, living room. The bedroom, the living room is air-conditioned room. The empty room is not air-conditioned room, including the

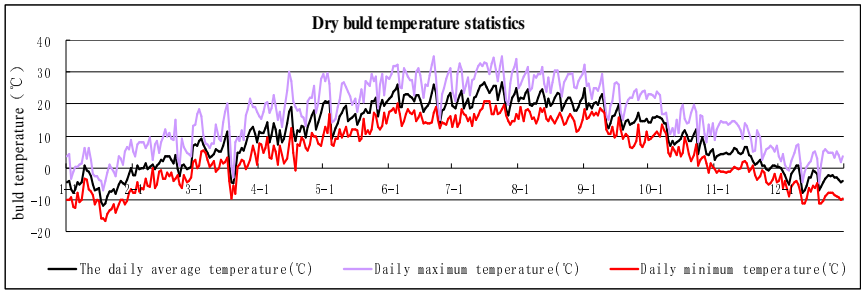

Fig. 3 The dry bulb temperature of every day in Lanzhou

bathroom, kitchen etc. The living room is able to hold a maximum of 3 people and the bedroom is able to hold a maximum of 2 people. Personnel heat divided into sensible heat and latent heat, the sensible heat is 61 Watt apiece and the latent heat is 73 Watt apiece. The maximum lighting heat is 5 Watt per square in the living room and 4 Watt in bedroom.

In order to facilitate comparison of Impact on building energy consumption in deferent thickness of external wall insulation layer, take the building without insulation as reference architecture. The annual Heating and air-conditioning energy consumption were simulated in deferent thickness of external wall insulation layer, from 10mm to 80mm, by using the DeST-h software. As well as the annual Heating and air-conditioning energy consumption was simulated in case of the building without insulation. The simulation results are shown in Table 3 and Fig. 4.

TABLE 3. THE ANNUAL TOTAL LOAD AND THE RELATIVE ENERGY SAVING RATIO

The thickness of the insulation layer/mm	Annual total load （kWh）			Relative energy saving ratio （%）	
	Heat load	Cooling load	Total load	Heat load	Cooling load
0	161458	11073	172529	0	0
10	85891	14060	99951	46.8	42.1
20	57707	17607	75314	64.2	56.3
30	43532	20246	63778	73.0	63.0
40	35011	22256	57267	78.3	66.8
50	29353	23872	53225	81.8	69.1
60	25515	25222	50737	84.1	70.6
70	22717	26307	49024	85.9	71.6
80	20641	27171	47812	87.2	72.2

From Table 3 and Fig. 4, we can see that heat load had decreased obviously when the exterior wall was insulated using extruded polystyrene board, and the insulation layer is thicker and the reduction of energy consumption is more. When the insulation layer thickness is up to 80mm, energy-saving

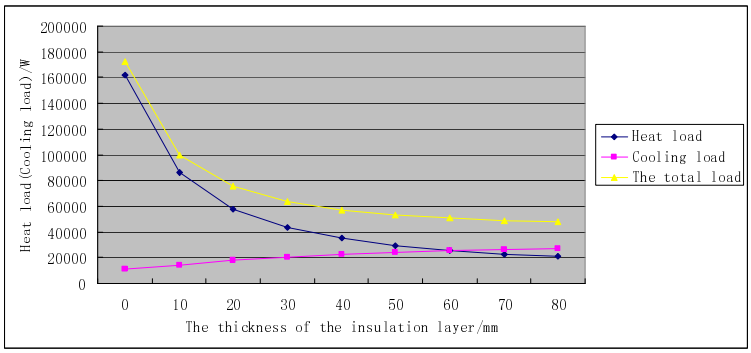

Fig. 4 Variation of load with insulation layer thickness

rate is 87.2% relative to the wall without thermal insulation. From above we can see that the energy saving effect is very obvious. But the cooling load is not reduced but increased when taking measures to insulate the wall. the reason is that the decrease of the heat transfer coefficient is advantageous to prevent that energy transfer from the high-temperature region to the low-temperature region; there the outdoor temperature is higher than the indoor temperature in summer daytime. But in the summer night or over season, the outdoor temperature is lower than indoor temperature; there is an energy transfer from the outdoor to indoor. Therefore the cooling loads of increased with the decreasing of the heat transfer coefficient.

Determination of economical insulation thickness

The thickness of the insulation layer is the main parameter of exterior wall thermal insulation performance in case that the thermal insulation material is determined. Also what can be seen from table 3, the percentage increases of energy saving is respectively 14.2%, 6.7%, 3.8%, 2.2%, 1.5%, 1%, 0.6% when he thickness of the insulation layer changes from 10 to 80mm and relative energy saving ratio tend to moderate. That is to say too much of the increase in the thickness of the insulation layer, the cost will increase, but energy-saving ratio will be reduce relatively. And then there is the total minimum cost of a certain insulation thickness of the wall. This particular thickness is the economic thickness of thermal insulation layer. Therefore, the optimal thickness of insulation will be determined through the economic analysis. At present the life cycle cost analysis on building is usually used as a kind of method of the total cost of economic analysis in foreign. Economical insulation thickness can be calculated with [3].

$$\delta_{op} = \sqrt{\frac{24ZPWF\varepsilon C_f(t_i - t_e)\lambda}{H_c C_i \eta_1 \eta_2}} - \lambda(R_i + R_e + R_w) \tag{1}$$

Where δ_{op} is the economical insulation thickness and the units is millimeter, PWF is The discount coefficient, η is the total efficiency of the heating system, $\eta = \eta_1\eta_2$， η_1 is transmission efficiency of outdoor pipe network, the value is 0.92. η_2 is the boiler efficiency， the value of the Coal fired boiler is between 0.73 and 0.82, the value of the Gas fired boiler is between 0.86 and 0.90[4]. H_c is Calorific value of fuel and it has units of kilojoules per kilogram or kilojoules per cubic meters. C_f is the price of fuel and the units is Yuan per kilogram or Yuan per cubic meters. C_i is heat preservation material cost, the units is Yuan per cubic meter. Z is Heating period, The heating period in Lanzhou for 126 days, R_i is heat resistance of inner surface and the value is 0.11 R_e is heat resistance of outer surface and the value is 0.043 (m^2·K)/W[4]. R_w is the thermal resistance of retaining structure, (m^2·K)/W; λ is thermal conductivity of thermal insulation layer, W/ (m·K) 。 t_i is indoor temperature and the value is 18 Celsius system. t_e is outdoor mean air temperature during heating and the value is 0.6 Celsius system below zero[5]

The life cycle present value factor PWF is not only determined by inflation rate i and the bank interest rate, but also determined by life cycle years N of the insulating layer[3].

$$PWF = \frac{1-(1+I)^{-N}}{I} \tag{2}$$

$$I = \frac{i-g}{i+g} \tag{3}$$

The current state loan interest rates i is 6.55%, the rate of inflation is 2.4%, use fixed of year is 10 years,The resultant for PWF is 8.09 by Formula (2) and (3)

The Equation of economical insulation thickness Can be simplified as followings on the condition of different fuel and Insulation materials (Different fuel calorific value, price and efficiency are shown in Table 4)

$$\delta_{op} = 852\sqrt{\frac{C_f \lambda}{H_c C_i}} - \lambda(0.153 + R_w) \tag{4}$$

TABLE 4 CALORIFIC VALUE, PRICE AND EFFICIENCY DIFFERENT FUEL

Fuel	Calorific value of fuel (MJ/m^3 or MJ/kg)	Price (yuan/kg or yuan/m^3)	Efficiency
Natural gas	9.92x103	2.21	0.9
Oil	10.94 x103	3.69	0.85
Coal	6.97 x103	0.3	0.65

When the residential buildings were heated using gas boiler ,The Equation of economical insulation thickness Can be simplified furthermore as followings

$$\delta_{op} = 12.7\sqrt{\frac{\lambda}{C_i}} - \lambda(0.153 + R_w) = 12.7\sqrt{\frac{0.03}{1800}} - 0.03(0.153 + 0.157)$$
$$= 0.04254\text{m}$$

From the above result of calculation, the economic insulating layer thickness is 40mm when the thermal insulation material is extruded polystyrene board, and from the above equation we can see that the economic insulating layer thickness determined by fuel and insulation materials in special area. So it should not be performed by the construction of energy-efficient design standards and recommended value experience value but it should be calculated according to the concrete conditions of the building. Which makes the building to achieve its economical and energy-saving character.

Summary

Heating, air conditioning load of the residential buildings were calculated by using the building energy simulation software DeST-h in Lanzhou city Based on the comparison of external wall with different insulation thicknesses and without insulation, the result shows that the total annual load can be reduced to 42% ~ 72%. But With the increase of the thickness of the insulation layer, the building load decrease slowly. Therefore the optimal thickness of insulation is determined by using the life cycle cost analysis. The economic insulating layer thickness is 40mm when the thermal insulation material is extruded polystyrene board and the heat source is the gas boiler in Lanzhou. The determination of the economy insulation layer thickness avoids blindly pursuing the insulation effect and ignoring the investment cost increases. Using of life cycle cost analysis method considering the entire life cycle energy consumption of the buildings during the construction and dismantling. This method is more scientific and reasonable. the result of analysis has the reference value for the actual engineering.

Keywords: Energy-Saving Standard, DeST-h, energy consumption, residential building

Abstract. This paper uses energy consumption stimulation software DeST-h to carry out stimulation study on annual energy consumption for heating of a typical residential building in Lanzhou city, a city in cold zones. We respectively calculated energy consumption under conditions of implementing "50% energy-saving standard" and "65% energy-saving standard", calculated the energy-saving rate, and did research on energy-saving ability, economy, emission-reducing ability of different energy-saving standards.

Introduction

Since《Design standard for energy efficiency of heating residential buildings》 was promulgated and implemented in 2006, The 65% energy-saving design standards has been implemented for residential buildings in Lanzhou. With《Design standard for energy efficiency of residential buildings in severe cold and cold zones》 [1] comprehensive implementing which put forward higher requirements of thermal performance standards for envelopes of residential building. This standard is the supplement to the 《Energy conservation design standard for new heating residential buildings》. Two standards were developed to putting forward different Residential buildings heating energy consumption were reduced to 65% and 50% respectively in new and old standard. According to energy-saving targets, it put forward measures of energy saving requirements for building heating design and building thermal. Nationally, the energy-saving effect for different energy efficiency standards in a specific area of specific simulation calculation is of rare occurrence. Jian Yao [2] did research in Ningbo area and Li Bai [3] made economic analysis under different energy saving standards in Changchun. Lanzhou city is located in cold (A) region and its climate is different from hot summer and cold winter zone and severe cold zone. Therefore this paper simulated the relative energy saving ratio under performing different energy saving standards, this study further analyzed economy, energy saving and emission reduction.

The ratio of energy-saving and emission reduction of the implementation of the "65% energy-saving standards compared with the implementation of the "50% energy saving standards" and how about the economy, witch is unable to draw by the theoretical analysis or experiment. So the simulation method is the best choice under the current conditions. Building simulation analysis software DeST[4] can analyze the energy consumption dynamically throughout the year under the hot and cold conditions. The dynamical simulation for a typical residential building is in accordance with the actual heating conditions. Analyzing the heating consumption at above two energy saving target. Because Lanzhou city is located in cold regions, there is not air conditioning in summer; the air conditioning energy consumption will be analyzed quantitatively.

Building model

Taking a residential building in Lanzhou city as the simulation object ,the area of residential building is 4676 square meters, shape coefficient is 0.342, and comprehensive window wall ratio is 0.16, the building has eleven floors, it is 2.9 meters high, the top floor is 3 meters high. Building toward the southern and Northern, the building model of DeST geometry model as shown in Fig. 1, The performance parameters of retaining structure are settled in accordance with the different energy-saving standard. For the sake of convenience, the residential building of "50% energy-saving standard" was taken as the benchmark residential. The parameters of benchmark residential are settled according to 《Energy conservation design standard for new heating residential buildings》 as shown in Table 1.

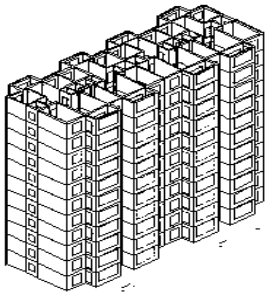

Fig. 1 DeST building model

Table 1. The thermal physical parameters of structure

Component name	50% energy-saving		65% energy-saving	
	Retaining structure material	Heat transfer coefficient	Retaining structure material	Heat transfer coefficient
Exterior wall	Expanded polystyrene board Concrete perforated brick	0.849	Extruded polystyrene board Concrete perforated brick	0.697
Inner wall	Ceramist concrete	1.52	Concrete air brick	1.2
Roof	Aerated concrete thermal insulation	0.68	Light steel structure	0.427
Floor	Reinforced concrete	3.05	Extruded polystyrene board	1.11
Exterior window	Standard Windows	4.7	Standard Windows	2.5

Simulation under different Energy-saving standard

The setting of indoor calculation parameters. Calculation parameters of indoor was stetted according to 《Design standard for energy efficiency of residential buildings in severe cold and cold zones》 and 《Design code for heating ventilation and air conditioning of civil buildings》 [5]. The meteorological data used in the simulation are come from typical meteorological year data issued by Technology Department of Tsinghai University and Meteorological Information Center Meteorological data of China Meteorological Administration. Lanzhou's 8760 hourly meteorological parameters were calculated by using DeST-h as shown in Fig. 2

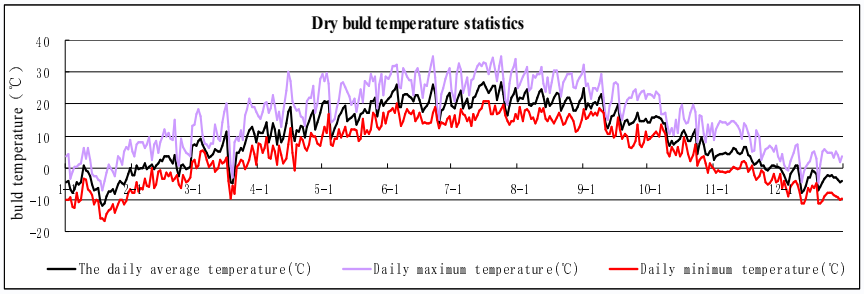

Fig. 2 The dry bulb temperature of every day in Lanzhou

The room functions of residential building is simplified as the bedroom, living room,. The bedroom, the living room is air-conditioned room. The empty room is not air-conditioned room, including the bathroom, kitchen etc. The living room is able to hold a maximum of 3 people and the bedroom is able to hold a maximum of 2 people. Personnel heat divided into sensible heat and latent heat, the sensible heat is 61 Watt apiece and the latent heat is 73 Watt apiece. The maximum lighting heat is 5 Watt per square in the living room and 4 Watt in bedroom.

Energy-saving analysis

Simulation results under different energy saving standards are shown as following Table 2.

Table 2. The annual total load and the relative energy saving ratio

Category	50% energy-saving	65% energy-saving	Savings	Energy saving ratio
Area	4676	4676	-	-
The maximum heat load	58.3	35.8	22.5	38.6
Annual total load (kW·h/ m^2)	63.1	42.1	21	33.3
The average consumption of gas (kgce·m-2)	7.73	5.17	2.56	33.3

From Table 2, we can see that heat load had decreased obviously when the "65% energy-saving standards implemented comparing with the "50% energy saving standards". The maximum heat load is reduced by 38.6% and annual total load is reduced by 33.3%.which means that Heating energy consumption value is reduced by 33.3%.From Table 2, we can see that annual heating gas consumption of residential buildings reduced from 7.73 kgce/m^2 to 5.17 kgce/m^2 when performing different standards, This residential building could be saved gas 9857Nm annually. By the end of 2011 statistics shows that residential area is 10450×10^4 m^2 and performing "65% energy-saving standards will save gas 22109×10^4 Nm in Lanzhou. That is to say energy saving potential of heating is very great

Emission reduction analysis

According to the emission quota of pollutants in China [5], the amount of pollutants produced by burning 1kgce can be calculated. the quota of pollutants are as following Table 3

Table 3 Pollutants produced by 1kgce kg

Contaminants	Emission index
CO_2	33.7
SO_2	0.237
NO_2	0.0126

Energy conservation and emissions under different energy-saving standards is shown in Table 4

Table 4 Energy conservation and emission analysis

Category	50% energy-saving	65% energy-saving	Emission reduction of the building	Emission reduction of Lanzhou
area（m^2）	4676	4676	-	300×10^4
The average consumption of gas ($kgce\cdot m^{-2}$)	7.73	5.17	-	-
CO_2 emissions（t）	1203.64	805.02	398.62	25×10^4
SO_2 emissions（t）	8.4	5.6	2.8	1800
NO_2 emissions（t）	0.44	0.29	0.14	90

The above analysis presented that harmful emissions decreased by 33.3% year-on-year when there are no taking other environmental protection measures, only considering the implementation of different energy saving standards. One building annual reduction of CO_2 emissions is 398.6t per year, SO_2 emissions is 2.8t per year and NO_2 emissions is 0.14t per year. Fatherly, reductions of CO_2 emissions is 25×10^4t per year, SO_2 emissions is1800t per year and NO_2 emissions is 90t per year in the entire city of Lanzhou. Thus it can be seen, the implementation of the "65% energy saving standards", can significantly reduce the emissions of harmful substances, environmental protection is of great significance.

Summary

Residential buildings energy consumption was simulated by using hourly energy consumption simulation software DeST-h in Lanzhou and The analysis result presented that the "65% energy-saving standards implemented comparing with the "50% energy saving standards". The maximum heat load is reduced by 38.6% and annual total load is reduced by 33.3%.which means that heating energy consumption value is reduced by 33.3%. reductions of CO_2 emissions is 25×10^4t per year, SO_2 emissions is1800t per year and NO_2 emissions is 90t per year in the entire city of Lanzhou. This study further shows that the implementation of"65% energy saving standards" can not only save energy, but also can reduce the emissions of harmful substances. On the other hand, the initial investment, operating costs and heating system will decrease.

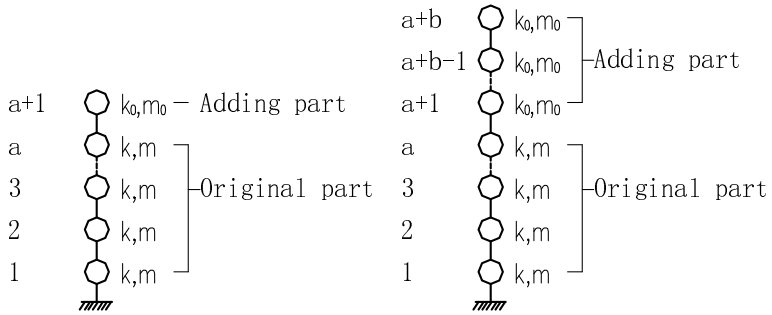
Keywords: steel adding storey, equivalent damp ratio; selecting models

Abstract: Characteristics and applying conditions of lightweight steel structures in adding buildings are introduced, and the correlative calculating methods in designing are also discussed. The optimal layers in adding are proposed by using bottom storey shear as target parameters. The reactions of structure adding optimal layers are analyzed to judge the adding capacity of original structure. The economy comparison of different materials in adding is also discussed by the parameter of material cost. Using an adding project as an example, an appropriate adding scheme is chosen by this method.

Introduction

With the development of Chinese urbanization, the conflict between increasing population and limits of city land has become sharper and sharper. Meanwhile, it is definitely forbidden to use cultivated land as housing land. Undoubtedly, retrofitting of existing buildings is both the best way to solve these problems and an important means to ease the population pressure.[1]



The traditional materials used in storey-adding are brick masonry; concrete; steel and etc., concrete structure is especially common used in adding project. Using the same materials as the original structures to add storey, the structure models are mature, and there're lots of corresponding specifications or guidelines for designers to follow, such as "Technical code for adding stories of brick-concrete structures of building" "Design code for strengthening concrete structure" and etc. Steel structure is a kind of structure with good seismic performances, high strength, and large energy dissipation. Concrete frames using steel as storey-adding material is a composite structure, which has a stiffness mutation vertically. The connection of different materials leads to the appearance of weak layer.

Structural system & Calculation model

The structure system after storey-adding is a composite structure, which has frame or brick structure as bottom frame and has steel frame or bent as the upper frame. The calculation model diagram must be consistent with the actual structure and connections. Meanwhile, the definite force transmission routes, reasonable structure calculation methods, and reliable measures should be adapted. As to concrete frame structure using steel to add storeys, the connection between the upper part and the lower part is so important that the upper steel system and the connection should be designed carefully, in order to avoid steel column base's failure caused to structure's geometric instability.

Seismic calculation

The magnitude of the earthquake effect is proportional to the mass of buildings. So light steel can effectively reduce the earthquake effect of the lower part of the structure which caused by storey-adding. It is worthwhile to note that both the mass and the stiffness between the enhancement layer and the original construction have a great difference. Due to the suppleness of the upper structure, high modes of steel have a significant effect, resulting in different vibration periods and different vibration acceleration of the original structure and the adding structures. In the bottom shear method, every storey is considered as a single degree of freedom, assuming vibration as linear form which ignores the influence of higher modes of vibration. Therefore, dynamic magnification factors should be multiplied to consider the effect of the high mode. In mode decomposition method, enough mode number should be selected which made the mass participation ratio close to 1. Only in this way, the effects of the high modes are considered enough. The damping ratio of concrete and steel is different, the material damping ratio of concrete is 0.05, while the steel 0.02. The damping ratio of the composite structure using different materials is not a constant, but a equivalent damping ratio ranged from 0.02 to 0.05 in various modes of vibration[5-8], which stands for damping and energy dissipation capacity of the structure system, and also affects the calculation results of whole structure analysis, especially for a more-adding-storey building, or a building located in the high intensity region. Under these situations, equivalent modal damping ratio is averaged by using the strain energy.

（a）One storey adding （b）b storeys adding

Fig 1 Mechanical model of composite structure adding by steel structure

$$[K]=\begin{bmatrix} 2k & -k & & & & & \\ -k & 2k & -k & & & & \\ & \cdots & \cdots & \cdots & & & \\ & & -k & k+k_0 & -k_0 & & \\ & & & \cdots & \cdots & \cdots & \\ & & & & -k_0 & k_0 & \end{bmatrix}=\left[\begin{array}{cccc|c} 2k & -k & & & \\ -k & 2k & -k & & \\ & \cdots & \cdots & \cdots & \\ & & -k & k & \\ \hline & & & & 0 \end{array}\right]+\left[\begin{array}{c|ccc} [0] & [0] & & \\ \hline [0] & k_0 & -k_0 & \\ & -k_0 & 2k_0 & -k_0 \\ & & \cdots & \cdots \\ & & -k_0 & k_0 \end{array}\right]$$

$$=\begin{bmatrix} [K_a] & [0] \\ [0] & [0] \end{bmatrix}+\begin{bmatrix} [0] & [0] \\ [0] & [K_b] \end{bmatrix}=[K_1]+[K_2]$$

Among them，$[K_a]$ is a matrix with $a\times a$ order，$[K_b]$ is a matrix with $(b+1)\times(b+1)$ order. Assuming the mode vector of the i th order vibration mode as ϕ_i, the mode vector relevant to structure 1(original structure) as ϕ_{i1}, the mode vector relevant to structure 2(adding structure) as ϕ_{i2},

mode damping ratio of the composite structure can be averaged by material's strain energy [7,9]:

$$\xi_i = \frac{\xi_1 \phi_{i1}^T K_1 \phi_{i1} + \xi_2 \phi_{i2}^T K_2 \phi_{i2}}{\phi_i^T K \phi_i}.$$

Rayleigh damping of different frequency may has certain effects on the calculation results, but the difference is small (within 5%), and it can be accepted in practical project. So using the former 2 natural frequencies to determine the Rayleigh damping is feasible in engineering.[10]

Different damping ratio causes different seismic response. The modifier formula is shown as follows[11]:

$$\alpha(T,\xi) = \alpha(T,\xi = 0.05) \cdot \beta(\xi,T), \text{ while } \beta(\xi,T) = \sqrt[3]{16.6\xi + 0.16}\left(\frac{0.8}{T}\right)^{\frac{0.05-\xi}{0.156+3.38\xi}}.$$

Put every equivalent damping ratio of each mode into the formula, and horizontal maximum affecting coefficient can be figured out.

Preliminary judgments of the number of adding storeys

Number of adding storeys is influenced by many factors: needs, planning requirements, the carrying capacity of the original structure (vertical bearing capacity, horizontal bearing capacity), the total cost of investment (adding & reinforcement), time limit for a project etc.

Using $F_{Ek} = \alpha_1 G_{eq}$ as the target parameters, assuming seismic intensity, the storey mass, loads, the original stiffness, and the adding-storey stiffness are all known, the optimal number of adding storeys can be found out. The larger the number of adding storeys is, the heavier the parameter" G_{eq} " is. In the description of parameter" α " in "code for seismic design of buildings[2]", there's a huge decline when the vibration period is in the range between T_g and $5T_g$. With the increasing of adding storeys" b ", the composite structure becomes more flexible, the vibration period increases rapidly, meanwhile, equivalent damping ratio ξ becomes smaller(approaching to the steel damping ratio). After comprehensive evaluation of the formula $\alpha = \left(\frac{T_g}{T}\right)^{0.9+\frac{0.05-\xi}{0.3+6\xi}}\left(1+\frac{0.05-\xi}{0.08+1.6\xi}\right)\alpha_{\max}$, it can be showed that in a certain range, with the increasing of " b ", the smaller " α " is. Further, there is an extreme point of" b ", so that made the target parameters be the critical point. It also can explain several examples in some literature[12 - 15] that the steel adding causes a smaller bottom shear.

An engineering example

Project overview

A reinforced concrete frame structure with two ground floors and one underground floor, located in the District of 7 degrees of earthquake intensity, second type of site. The construction designed in 2003 has been employed less than 10 years. The original construction area is 6480m^2 (not including the underground area). Adding storey is chosen to meet the requirements of the owner considering the construction period and investment scale.

According to the inspection report, the structural component basically meets the relevant requirements of "code for seismic design of buildings" and "code for design of concrete structures", reinforcement and reconstruction are practicable.

Calculation & Scheme Analysis

Seeking for the optimal number of adding-storeys

The original structure is two story concrete frames, assuming that the stiffness of the beam is infinite. Inter-story shear stiffness of every concrete floor is $k_1 = k_2 = 1.0\times10^7 KN/m$, mass of every concrete floor is $360t$; while inter-story shear stiffness of every steel floor is $k_3 = 3.2\times10^6 KN/m$, mass of every steel floor is $255t$. The damping ratio of concrete and steel are 0.05and 0.02. On the basis of former theory, a procedure is programmed by MATLAB to figure out the equivalent damping ratio of composite structure, which can modify the seismic spectrum. The target parameter presented under the premise of less than 40-meters-tall, the shear deformation takes an important role. Taller the structures are, more effect the high modes take on the bottom shear force, so the assumption does not exist any longer. The first critical point was selected as the optimal point. The result shows: it is 3floors that has the less bottom shear force.

Using design program to calculate, the result shows vertical capacity can bear the adding loads. It is practical to add three floors. To respect owner's idea, we take the scheme of adding two floors.

Economy comparison of concrete and steel adding storey

The computation and analysis shows: In the condition of using concrete structure to add, almost 30% of the columns need to be reinforced, 30% of planar member of the second floor need to be reinforced because of the increasing load and function changes. In the condition of using steel structure to add, only 4% of the columns need to be reinforced, 25% of planar member of the second floor need to be reinforced because of the increasing load and functional changes.

Steel is worth 5800 Y/t, and concrete is worth 300 Y/m^3. The material costs of steel-adding part are 290000; while the material costs of concrete-adding part are 814600. From the sight of reinforcement, the material costs of reinforcement under steel-adding are 800000 less than the costs under concrete-adding. Of course, reinforcement costs are far more than the material itself.

The function of this project after alteration is for the commercial use. In consideration of the construction character, the duration, costs, disturbance to the surroundings, and the economic interests bring by early finished, steel structure takes certain advantages of concrete.

Conclusion

Using steel structure to add can reduce the earthquake effect brought by the increasing storey. A reasonable structure should be chosen by comparing characteristics of all kinds of light steel structure, and considering the actual construction conditions. The connections between adding-storey and original structures should be paid enough attentions on avoiding steel column base's failure caused to structure's geometric instability. Light steel must be designed according to the seismic code; the lower structure can only meet the standard for seismic appraiser. Through economic analysis and comparison, the light steel costs are lightly higher than concrete. Meanwhile, steel structure disturbs less; constructs assembly; can effectively shorten the construction period. After all, steel structure has a better comprehensive benefit. The seismic response of the entire structure is affected by adding-storeys, adding mass and stiffness. There are no clear provisions or instructions to this composite structure, which limits development of the light steel reinforcement in a certain extent. Too much details still need to be researched.

Keywords: Compacted loess; Finite element analysis; Rainfall; Infiltration; Moisture content

Abstract: Because of evapo-transpiration, compacted loess road embankments were considered to be in a partially saturated state in both arid and semi-arid regions. Based on previous studies and the theory of unsaturated soil mechanics, a numerical analysis of rainfall infiltration in a compacted loess road embankment was conducted. The transient seepage characteristics and moisture migration patterns of the moisture in the embankment were analysed. The results showed that after precipitation, the moisture profile of the compacted loess could be separated into three zones .The data also showed that: under the effect of gravity, the water continued to migrate into the embankment after the rainfall had ended. In time, the saturated zone became partially saturated as the moisture content decreased, whereas the moisture content in the conducting and humid zones increased and the wetting front moved downward. The data also showed that the depth of the conducting and humid zones increased in time, but that the moisture content in the conducting zone increased along a linear gradient with depth, while the moisture content in the humid zone decreased in a similar manner.

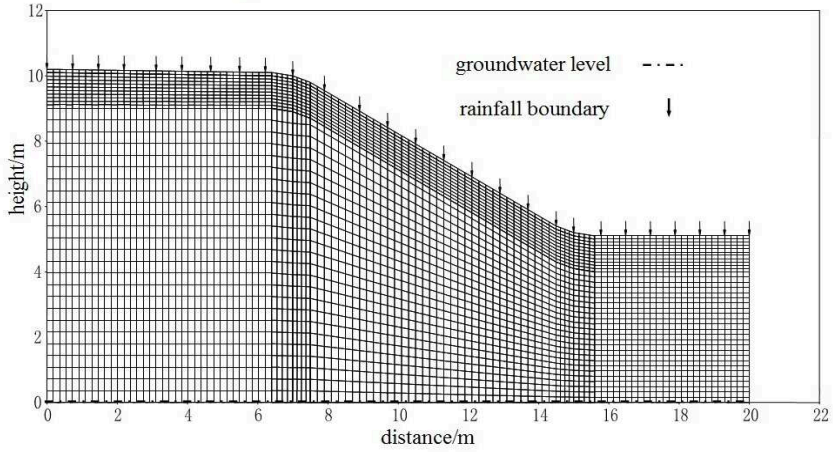
Introduction

Analysis of seepage within soil zones having different saturation ratios is a common objective for those investigating groundwater movement. The analysis of such problems is complex and the frequency of occurrence of landslides in natural ground, earth dams, railway and highway embankments makes the study of rainfall infiltration on compacted loess in unsaturated seepage conditions significant. Green and Ampt (1911)[1] were the first to describe the process of saturated soil infiltration accurately when they suggested their analytical solution for horizontal infiltration in a homogeneous, dry soil; Richards (1931) [2] uses the law of conservation of mass in his analysis of unsaturated seepage, Rubin (1968)[3] proposed a 2-dimensional finite difference numerical solution of Richards's control equation; Freeze (1971)[4] studied transient seepage flow in a mixed (saturated/unsaturated) underground aquifer, elaborating and summarising the numerical solution of his finite difference method; Remson (1971) [5]undertook a comprehensive evaluation of the finite difference method as applied to saturation-unsaturated seepage. Nenman (1973, 1974, 1977)[6,7,8] was the first to simulate the problem of unsaturated seepage by the use of the finite element (FE) method. Wu (1999, 2000)[9,10] and Peng (2002)[11] studied the FE numerical simulation of transient seepage in an saturated-unsaturated soil and improved upon the transient unsaturated seepage finite element approach developed by Nenman. Based on the theory of unsaturated soil mechanics, and by using the FE method to analyse the transient seepage in a typical loess railway embankment under rainfall infiltration, this research explored the seepage characteristics and moisture migration patterns in the process of humidifying deformation in compacted loess.

The Finite Element Method

The FE method, in which the basic concept is that the area under evaluation is discretised into inter-connected finite units (the elements), can simulate the geometrical shape of complex evaluation areas. The unknown field function over the evaluation area expresses each of its sub-regions by

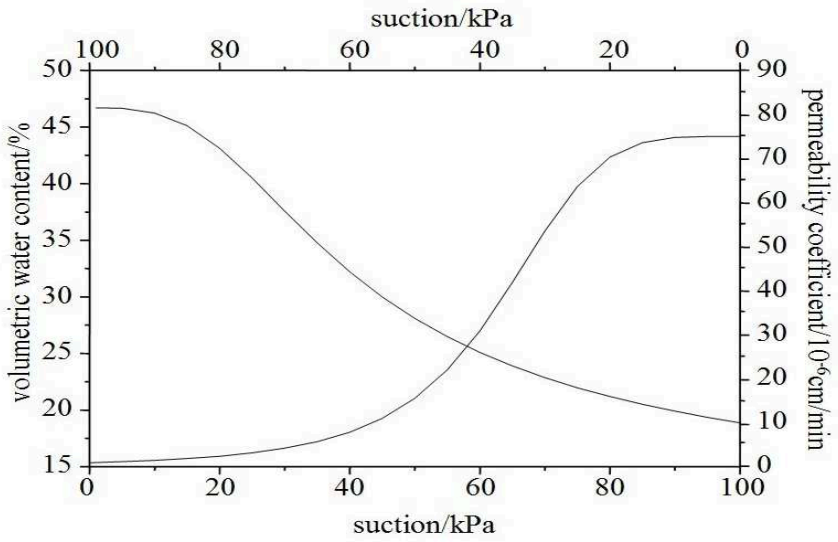
approximation function which is assumed to apply to each unit. Because of the non-linearity of the saturated-unsaturated seepage equation, Galerkin's method of weighted residuals is applied: this method requires the substitution of an approximate solution into the governing general differential equation and the subsequent elimination of the weighted average over the whole problem. The gap between the premise and the approximate solution is called the margin of the equation which is minimised en route to a solution.



Under complicated boundary conditions, the seepage characteristic of unsaturated soils can be calculated by such a numerical method. Two main elements must be taken into account with regards the unsaturated seepage caused by rainfall infiltration: the first is the varying infiltration rate, which results from changing the external conditions during precipitation; the second is the migration and distribution of the infiltrated water within the soil mass. The calculation of unsaturated seepage deals with the first of these issues as a boundary condition problem and the second as a transient seepage field problem.

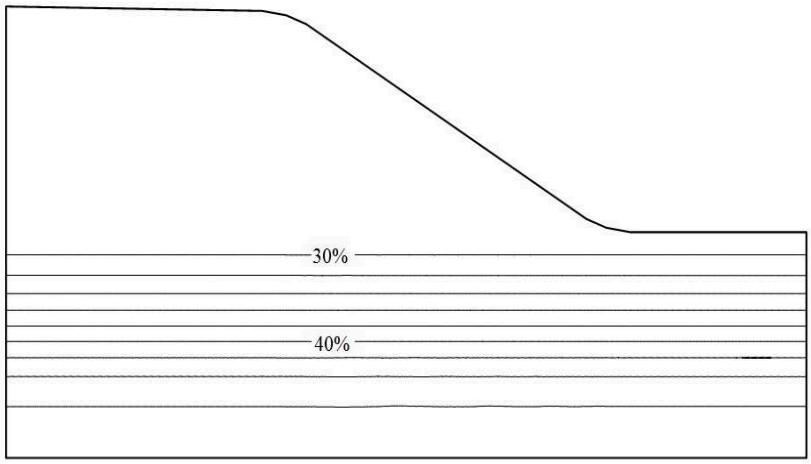
The solution method for problems incorporating a raining boundary condition influences the infiltration and distribution of the water in the soil mass: this affects the simulated results of the unsaturated seepage. Under the present unsaturated transient seepage simulation, there were three methods for handling the rainfall infiltration as a boundary condition: the first took the surface nodes as the known flow boundary, so the value was the infiltration rate or the rainfall intensity (i.e. it was assumed that all the rainfall had infiltrated the soil mass); the second defined the surface nodes as a known water head boundary (i.e. it was assumed that the suction of the surface nodes was zero during precipitation) and then calculated the amount of the water infiltrating the soil according to its unsaturated seepage coefficient and hydraulic gradient under negative pressure; the third was to transfer the surface nodes onto the boundary. When the rainfall intensity was less than the saturated seepage coefficient, the entire rainfall volume infiltrated the soil, so the boundary conditions became equivalent to the first category. When the permeability coefficient of the surface nodes was equal to that pertaining to saturated seepage, the surface nodes were converted to a known head boundary. In other words, this method took the saturated seepage coefficient as the infiltration capacity, which was then used as the factor by which the authors judged the conversion of the boundary. The third category of boundary condition was applied here to simulate the distribution and migration of infiltration moisture in the loess filled embankment slope beneath a railway.

Determination of Parameters and Geometry



The loess railway embankment analysed here as a semi-infinite symmetrical half-space is shown in Fig. 1. The height of the embankment was 5 m, the width of the pavement was 7 m, and the slope was 1H:1.5V. The mesh incorporated the ground at up to 5 m from toe of the slope and some 5.1 m depth below original, natural ground level. The shoulder and toe of slope were smoothed to eliminate boundary discontinuity effects. The upper surface, shoulder, slope, and its toe had an applied rainfall boundary condition: the base and other two sides were set to zero flux conditions under a static phreatic surface assumed to lie at 0 m as indicated in Fig. 1.

Fig. 1 Geometrical model and FE mesh



The dry density of the subgrade fill was 1610 kgm^{-3} (equivalent to 93 % relative density), the SWCC and unsaturated penetration coefficient curves are shown in Fig. 2.

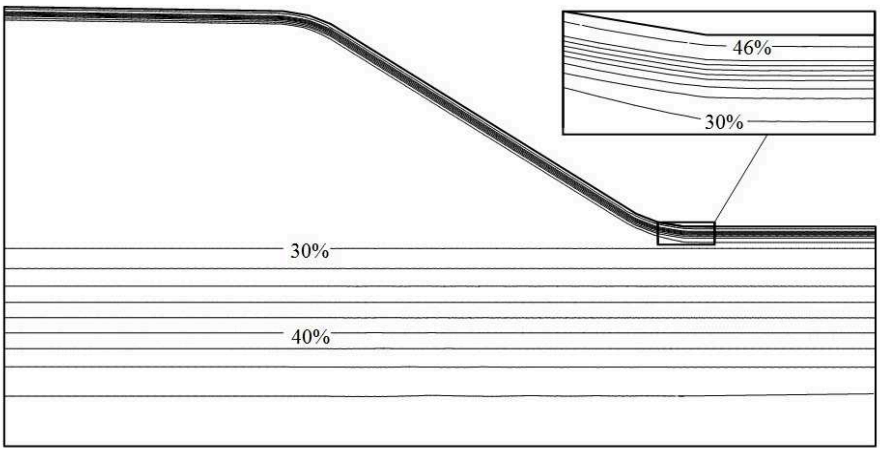
Fig. 2 SWCC and penetration coefficient curve (ρ_d = 1610 kgm^{-3})

The initial volumetric moisture content of the slope, as shown in Fig. 3, was 28 %, which was the optimum moisture content of the subgrade.

Fig. 3 Section of initial volumetric water content

A rainfall intensity of 3.4 × 10^{-3} cm/min for 24 h was chosen as the rainfall boundary condition. Also, nine days after cessation of precipitation, the cloudy conditions were deemed to have prevented evaporation so the water migrated under the action of gravity alone. The author's analysis started from the distribution and migration of the moisture within the embankment at cessation of precipitation and continued for s further 10 days.

Discussion



Analysis of Transient Seepage During Precipitation

The volumetric water content contour map of rainfall migration in one day is shown in Fig. 4 where it can be seen that the infiltration was lower in the compacted loess and that it reached a depth of infiltration of approximately 0.5 m, which placed the wetting front within the region typifying shallow unsaturated infiltration.

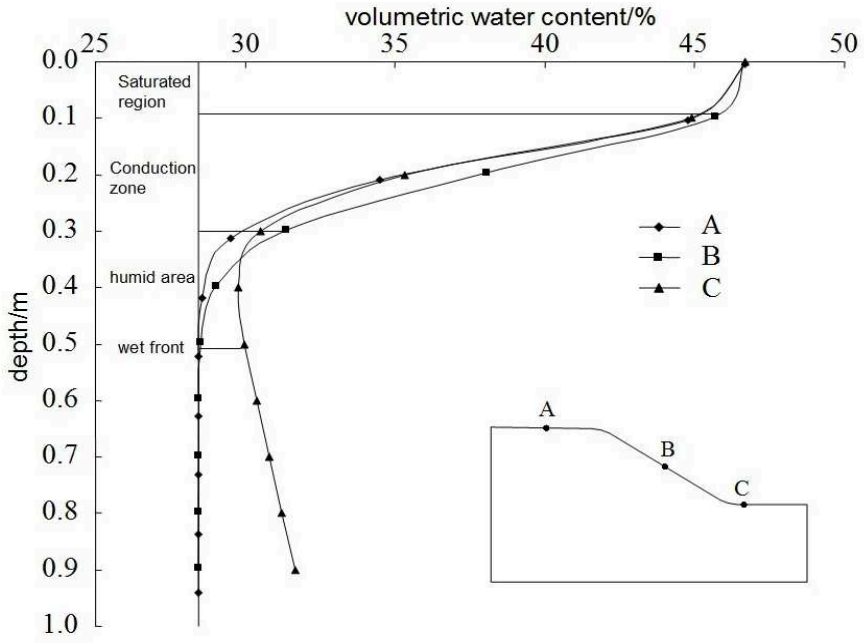
According to this research, the water content in a uniform soil under the influence of rainfall can be divided into four zones: a saturated zone, a transition zone, a conduction zone, and a humid zone. The leading edge of the humid zone represented the wetting front. Each zone had the following

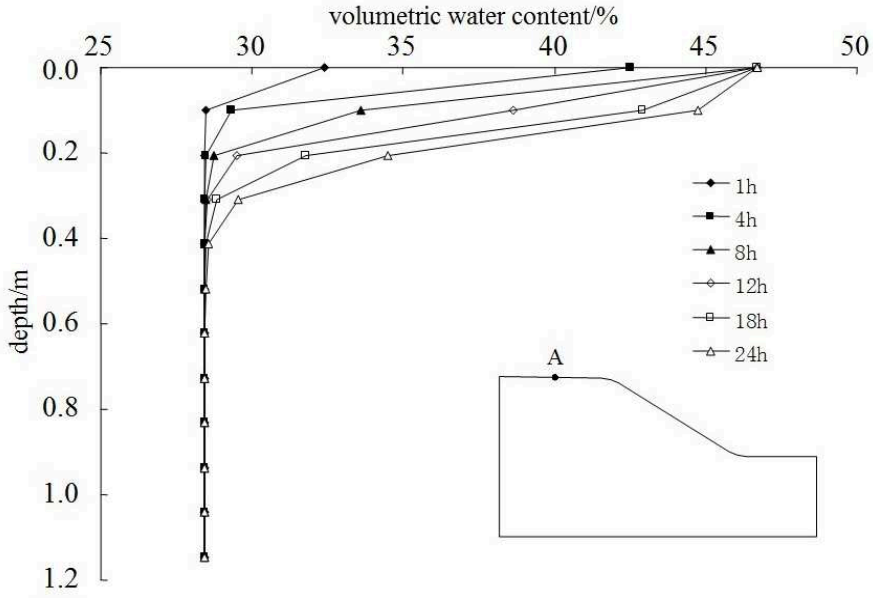
characteristics: a saturated region of only a few millimetres depth which was relevant to the ponding time, a transition region, generally several centimetres in depth wherein the moisture content decreased rapidly with depth, a conduction region which was typically a thicker, unsaturated zone of high moisture content that remained little changed with depth, and a humid region in which the moisture content differed from that in the conduction zone and was locally higher than the initial water content. The wetting front was a steep front formed between that soil still at its initial moisture content and that affected by the unsaturated hydraulic gradient.

Fig. 4 Section of volumetric water content for one day's rainfall

The moisture content of the slope and its toe varied with depth as shown in Fig. 5. There was no obvious transition but the rainfall induced volumetric water content could itself be further sub-divided into: a saturated zone, suffused with water to a depth of approximately 10 cm; a conduction zone, about 20 cm thick and subject to smaller variations in moisture content as well as a smaller equivalent linear rate of change with depth; and a humid zone, some 20 cm thick, in which the moisture content differed significantly from that in the conduction zone which was itself also at a greater moisture content than at the outset.

Fig. 5 Variation of moisture content with depth after rainfall





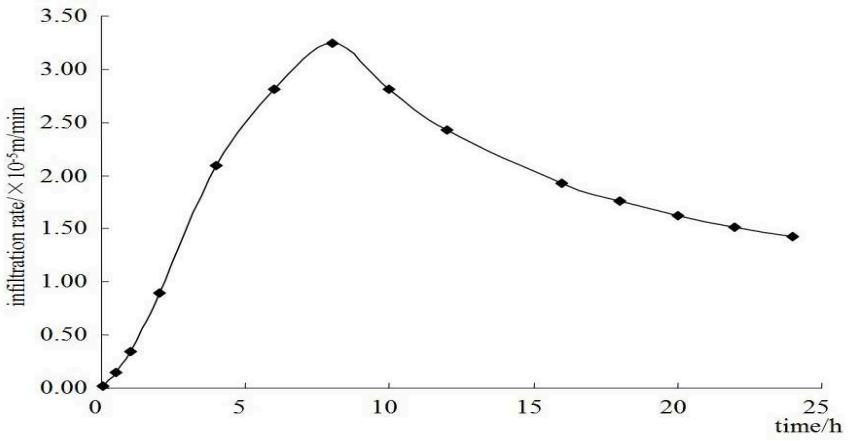


Fig. 6 shows the change of moisture content with depth and time: the upper surface became saturated and the wetting front propagated as the rainfall increased.

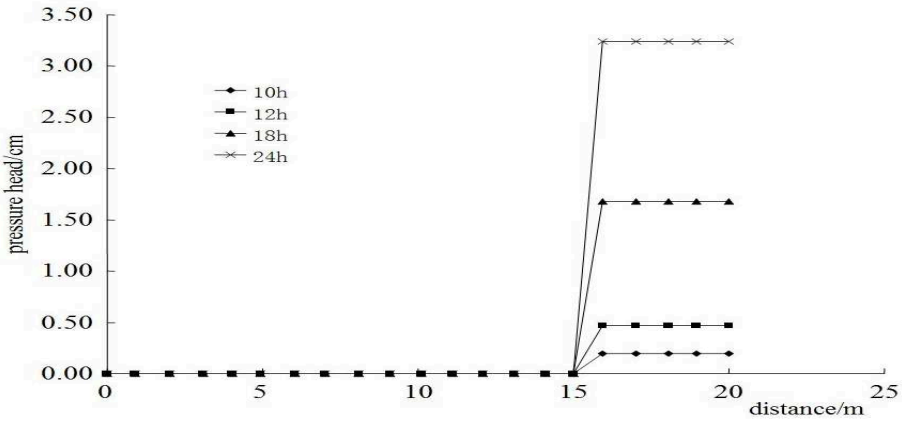
Fig. 6 Change of moisture content with the depth at different time



The infiltration rate variation curve at the rainfall boundary is shown in Fig. 7. There were three stages in the development of the equilibrium moisture content: initially, the moisture content was low and the infiltration rate started to increase with the wetting of the surface (Fig. 6).The surface moisture load increased during precipitation and indeed for up to 8 hours thereafter, the infiltration rate was equal to the rainfall intensity, then the soil became saturated (Fig. 6). The infiltration rate then decreased as it tended to an eventual equilibrium, stable, state: the steady state infiltration rate was also dependent on the properties of the soil.

Fig. 7 Change of infiltration rate during the rainfall

The accumulation of moisture at the bottom of the mesh during rainfall is shown in Fig. 8. There were surface stream-flows, slope run-off, and the surface began to pond after 8 hours' precipitation. The pressure head at both the upper surface and down the slope were held at zero throughout, while the pressure head at the bottom increased with time and the seepage reached a depth of 3.24 cm after one day's rain.

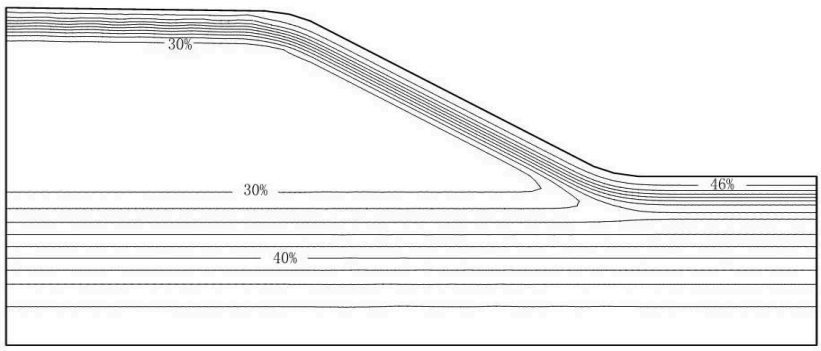


Fig.8 Variation of the accumulation of water at the base of the mesh

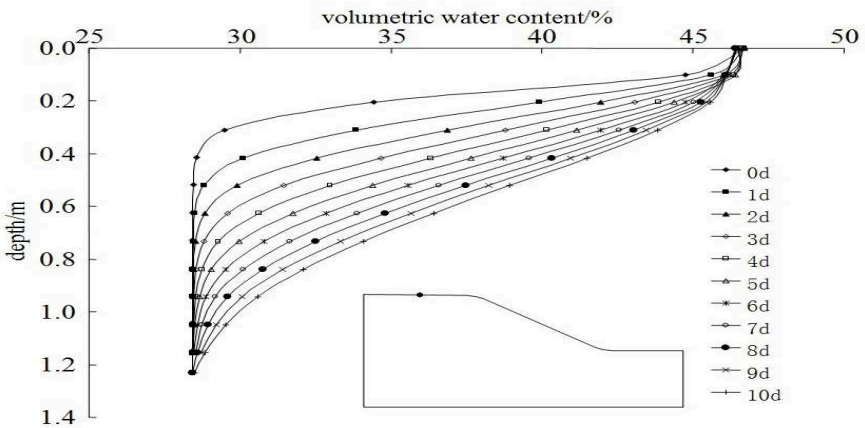
Migration of Embankment Moisture after Rainfall



The distribution of volumetric moisture content 10 days after the cessation of precipitation is shown in Fig. 9. compared to the conditions shown in Fig. 4, the moisture had continued to migrate into the embankment under gravity, the thickness of the zone nearest to the surface was thicker at approximately 120 cm and its volumetric moisture content exceeded 28 %. As a result of bottom infiltration, the thickness of this moisture content zone within the slope area increased significantly.

Fig. 9 Volumetric moisture content 10 days after the cessation of precipitation

The variation in moisture content with depth upon cessation of precipitation and onwards for a 10 day period is shown in Fig. 10: the saturated area became partially saturated which implied that the moisture content decreased, the wetting front propagated downwards carrying additional moisture into the conduction, and humid, zones whose extents widened over time. The rate of change of moisture content with depth increased in the humid zone and decreased in the conduction zone.

Fig. 10 Variation of moisture content with depth upon cessation of precipitation

Conclusions

After the rain, the compacted loess moisture profile could be sub-divided into three zones according to infiltration rate: a saturated zone, a conducting zone, and a humid zone. The saturated zone was approximately 10 cm thick. The conducting zone had a thickness of approximately 20 cm and its moisture content decreased linearly with depth. The humid zone had a thickness of approximately 20 cm and its moisture content reverted to the original moisture content after the rainfall.

At the onset of precipitation, the surface of the soil became wetter, but with a low moisture content and an increased seepage rate. By the end of the rainfall event, the moisture content had increased until the eighth hour, whereupon the seepage rate balanced the rainfall intensity, and the soil surface had become saturated. From then on, the seepage rate decreased and stabilised: thereafter the steady state seepage rate was governed by the properties of the soil.

Under gravity, the water migrated into the embankment after the cessation of precipitation; eventually the saturated zone at the end of the rainfall event had become partially saturated as the moisture content decreased. While the moisture content in the conducting and humid zones increased, the wetting front moved downwards. The size (depth extent) of both the conducting and humid zones expanded over time. The moisture content in the conducting zone increased linearly with depth, while the moisture content in the humid zone decreased linearly with depth.

Numerical Analysis on Synergetic Behaviors of AE in Concrete Failure Process

Li hua Wei

College of Architecture, Linyi University, Linyi, Shandong 276005

35809831@qq.com

Keywords: Concrete failure; AE; Synergetic effect

Abstract: The AE phenomenon can show the laws of concrete break well. In virtue of researching the relationship between inner structure state change and AE characteristic, the synergetic characteristic of AE in the concrete failure process was analyzed. Opened out the laws of concrete failure on high levels, and beneficially discussed the synergetic characteristic of AE. It is value to forecast the trend of concrete stability before failure and nondestructive testing.

Introduction

AE signal in the concrete failure progress will be emitted. Although AE technology is potential in concrete failure mechanism analysis and practical engineering, its theoretical basis still falls behind its technology development. A great deal of results of examination and scene are lack of rational theory analysis and the relationship between AE rule and patulous cracks also can not be described validly. As a result, the auspice of concrete failure has not been mastered accurately yet. The monitoring and forecast in application mostly depend on experience judge. The reliable criterion and theory foundation are absent. Those lead to low success ratio and unexpected effect. Restrict AE technology application. So the relationship between AE signal and cracks spread are confirmed and AE will be an important monitoring technology of failure.

In order to make concrete failure process clear, we should start with the whole propagation of the crack occurrence and its development, then study the inherent law of the failure character transform systematically.

Because of the complexity, fuzziness, nonlinear and indeterminacy of the character, the traditional mechanics can not be used commendably[1]. The nonlinear science, such as synergetics, catastrophic theory, chaos and fractal, have already been put into application [2~4].

Description on Synergetic Effect of Concrete AE Parameters

Establishment of Theorder Parameter Evolutionary Master Equation of Concrete Failure

Assume that the order parameter of the whole system is *Y*, which is AE counts rate. The order parameter of the subsystem parameter is *X*, which is the event counts rate. The change of the AE time counts rate can represent the whole process of concrete failure.

For the change of order parameter *Y*, assume that attenuation l is direct proportional to *Y*, and attenuation velocity $k_1 > 0$, then $l = -k_1 Y$.

For increase *m*, assume that s_1 is the rate of increase, and $s_1 > 0$. Because rather big crack propagation will lead to secondary crack' development, the influence of the subsystem must be considered. [5] indicated that the rate of increase of bifurcate affairs is direct proportional to the square of the former event counts. The increase *m* can be expressed as $m = h_1 X^2 + s_1 Y$.

So the variable equation of order parameter *Y* can be written as

$$\frac{dY}{dt} = -k_1 Y + h_1 X^2 + s_1 Y \tag{1}$$

And the variable equation of sub system *X* is

$$\frac{dX}{dt} = -k_2 X + h_2 Y + s_2 Y \tag{2}$$

Where k_2 is the attenuation of velocity, s_2 is the increase of velocity, and $s_2 > 0$.The change of the order parameter of the whole system represents evolution process of concrete failure. Because there are associated items in equation (1), the expected solution can not be gained. It can be simplified by the slaving principle of synergetics.

From Eq.2, we also find that

$$X = \frac{h_2 Y}{k_2 - s_2} \tag{3}$$

Put into Eq.1, we will have

$$\frac{dY}{dt} = -mY + nY^2 \tag{4}$$

Where $m = k_1 - s_2, n = \frac{h_1 h_2^2}{(k_2 - s_2)^2}$,From Eq.4 we can find that the coupling action between system and subsystem also restrict and is associate with the change of order parameters. The interaction is realized by positive and negative feedback.When $h_1 < 0$, $n < 0$, it is a negative feedback; $h_1 > 0$, $n > 0$, it is a positive feedback.

The Solution of Order Parameter Evolution Equation

(1) Analysis on the stable solution of order parameter evolution equation

In Eq.4, set $dY / dt = 0$, the stable solution will be gotten.

$$Y_1 = 0, Y_2 = m / n \tag{5}$$

When $Y_1 = 0$, it is a disorder state. Corresponding to the unloaded concrete it is a stable balance state and there is no AE.

Make linear stability analysis on $Y_2 = m / n$. Assume that μ is the perturbation near the steady state.

$$Y = Y_2 + \mu \tag{6}$$

Put Eq.6 into Eq.4 and ignore quadratic term of μ.

$$d\mu / dt = m\mu \tag{7}$$

The solution of this linear equation is

$$\mu(t) = \mu(0)e^{mt} \tag{8}$$

The stability of stable solution Y_2 depends on the sign of m. When $m < 0$ ($k_1 < s_2$), the stationary state is stable. In physical meaning, when the increase of the counts rate is bigger than that of attenuation, the AE order is stable.

(2) Analysis on the unstable solution of order parameter evolution equation

The unstable solution of nonlinear differential equation of Eq.4 is

$$Y(t) = \frac{1}{a + be^{mt}} \tag{9}$$

Where $a = \frac{m}{n}, b = \frac{m - nY(0)}{mY(0)}$,When $m < 0$ ($k_1 < s_2$), the increase of AE counts rate is bigger than that of attenuation. It is an active stage. From Eq.9, we can see that the AE counts rate increase by time.

When $m = 0$, it is corresponding to the phase that the counts rate changes relatively steady. The unstable solution is

$$Y(t) = \frac{Y(0)}{1 - Y(0)nt} \tag{10}$$

If $n < 0$, the order parameter will decreases by time. That contributed to the frequent generation of big ruptures results in the distribution of concrete stress. The AE counts rate in unit time is reduced. But if $n > 0$, the order parameter will increases by time. When reduce $Y(0)nt$ to 1, the total AE time will be infinite. Obviously this is corresponding to the catastrophic state.

Numerical Simulation on AE Phenomena in Concrete Failure Process

Simulation test was performed on the failure process of concrete specimen by RFPA2D. The size of specimen is 100mm×100mm, poisson ratio is 0.2, compressive strength is 40Mpa, and elastic modulus is 32.5Gpa. The specimens are loaded by displacement and the increase is 0.001mm in one step.

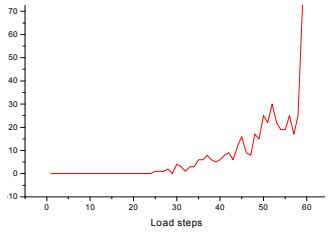

Fig.1 The 1st to 82th steps of AE counts

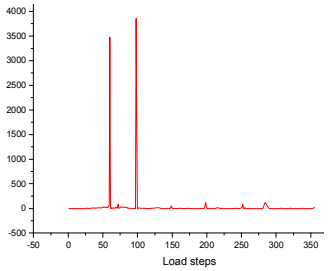

Fig.3 Whole failure propagation

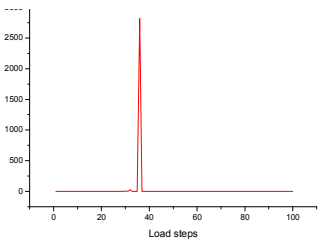

Fig.4 100 times of the 83th step

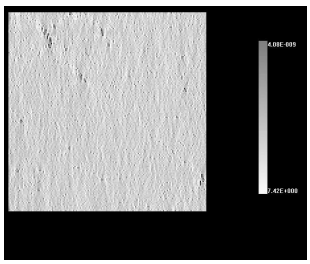

Fig.5 Failure figure of the 59th step

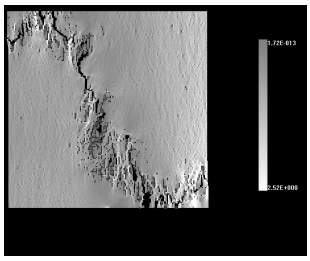

Fig.6 Failure figure of the 60th step

Synergetic Description on AE of Concrete Failure Process

According to the synergetic analysis and numerical simulation results, crack generates and develops gradually at the initial stages of load, and the AE counts increase. Here the complexity is also enhanced. When the load achieves a certain level, crack propagates quickly and induces to the AE crack increases sharply. The system is catastrophic. After this stage, the stress will be distributed again and the propagation action goes release. The AE count descends accordingly. So the whole load process is a cycle process that the AE counts rate undergoes relatively calm increase- catastrophic- attenuation- calm increase- catastrophic.

Conclusions

Due to dynamic, real-time, and the advantages of small influence on the structure of AE, the concrete nondestructive testing technology in engineering application will more and more widely. Because acoustic emission signal itself is complicated, effective feature extraction is difficulty, and acoustic emission parameters is disunion, all will influence acoustic emission directly to apply into the theory research and engineering application. In this case, the introduction of new theories, new methods to carry on the research to this problem are very necessary. Based on the study of numerical simulation method, and the combination of concrete from a new perspective, the failure process of the phenomenon of acoustic emission preliminarily analyzed. Provide new idea for concrete acoustic emission theory research and application.

Keywords: Dest-c; office building; energy consumption

Abstract: Taking Lanzhou meteorological condition as the background, this article simulates the energy consumption of heating system in an office building of Lanzhou using simulative software Dest-c under different building envelopes, and attained the load distributed curves and the detailed energy consumption about the system of heating and air conditioning in two different conditions, and supplied the new idea to validate the construct ion of energy consume guideline in this area.

In our country, Heat preservation and insulation performance of building envelope is very poor in cold regions. Generally, the energy consumption of the per unit building area is about 3 times than the developed countries under similar climate conditions[1]. Heating energy consumption of office building occupies a large proportion in the energy consumption of public buildings, so it is very important to research on energy conservation in office buildings [2]. This paper adopts an office building in Lanzhou as a model of this heating system. Using a simulation tool package that is developed by Ting—Hua University (Dest) for designing the building hot environment, the currently heating load of the building modeled during heating season can be calculated. The values of the maximal load and the currently maximal load can be obtained from the simulation results.

Geography and climate conditions in Lanzhou area

It is very long, cold and dry in winter in Lanzhou city, range, large diurnal, there is large different temperature between day and night. Table 1 is the coldest month outdoor temperature change curve, It shows, the minimum temperature in one day is -16.86℃, the maximum temperature is 3.7℃, the average temperature of the month is -5.53℃. The Number of days that the average daily temperature is less than or equal to 5 ℃ are 25% of the days, the Number of days that the average daily temperature is less than or equal to 5 ℃ are 25% of the days, so it need more days for heating.

The Theoretical Study

The Building Thermal Load

The thermal loads is made up of convection heat consumption, radiation heat consumption and interference heat consumption, heat passes from the outside surface to the inner surface of the enclosure structure and then pass to the indoor air. The heat load is made up of heat consumption of structure heat transfer and heat consumption which heating ventilation generated. And the second one is decided by the air circulation ratio, the first one is according to the type of calculation:

$$Q = \alpha KF(t_n - t_w) \quad (1)$$

Among them： K —Heat transfer coefficient of envelopes structure, W/m^2•℃; F —The area of the retaining structure,m^2； α —The correction temperature factor of different envelopes structure；

t_n—indoor calculation temperature in winter，℃； t_w—The outdoor calculated temperature of heating in winter,℃。

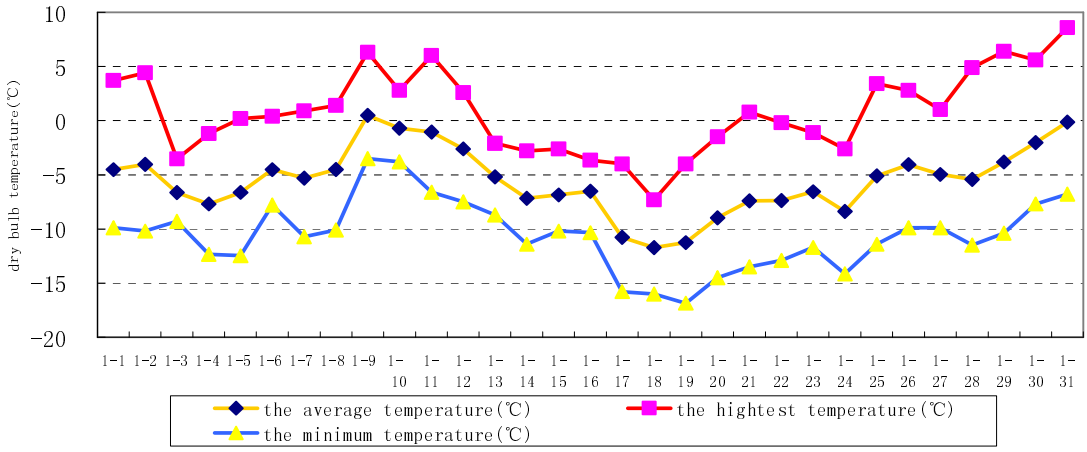

Figure 1 The Coldest Month Outdoor Temperature Change Curve

General Situation Of Building

The building models is a office buildings in Lanzhou city, and it has three layers, the height of each layer is 3.6 m, the building's area is 1580 m^2, the shape coefficient is 0.22, the area of window than wall is: east to 0.03, south 0.12, west 0.03 and north 0.17, the thermal parameters of envelopes structure are shown in table 1. Architectural appearance as shown in figure 3.1. The building including hall, office, office, stair, corridor and toilet etc. the generated building of modeling shows as Figure 2. The building includes hall, office, office, stair, corridor and toilet etc.

TABLE 1 THE THERMAL PARAMETERS OF ENVELOPES STRUCTURE

building envelope	*structure*	*Heat transfer coefficient* $W/(m^2 \cdot K)$
wall	20mm Cement mortar+240mm Hollow brick + 20mm lime mortar	1.37
window	6 mm Ordinary glass	5.7
roof	5mm mixed mortar+100mm ceramsite concrete +95mm reinforced concrete + 5 mm plaster	1.05

The Building Model

The Establishment Of Building Geometric Model

According to construction drawings to build a model in the Dest, it mainly includes the architectural appearance size, the building envelops structure parameters such as heat input, room internal interference, setting of operating time, heating operation conditions, such as figure 2.

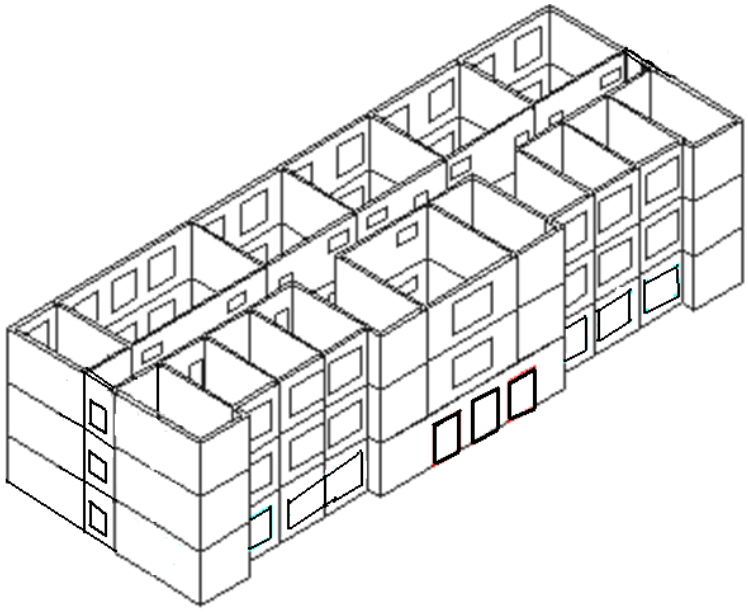

Figure 2 The Generated Building By Dest Modeling

The Results of the Simulation By Dest

By the building thermal environment simulation software Dest, We get the all-year hourly office building energy saving heat load of 134.5 kW h, the building heating season heat load index is 85.13 W/m^2. According to the design experience, such office buildings' heat load estimate index for 65 W/m^2 in Lanzhou. The office building heating load index is a little bigger, it is mainly because the building is located in cold areas, according to the requirement of《public building energy efficiency design standard》, the office buildings are not up to standard, high heat transfer coefficient leads to higher energy consumption, so the energy-saving renovation must be done.

The DeST Simulation Results and Analysis

Analysis For Different Thermal Insulation Thickness Of The Wall On Building Energy Consumption

The most simple and effective way is to remove the outside wall surface mortar , and then add thermal insulation layer in the surface of palisade structure, according to the ministry of public security fire rating requirements for the wall heat preservation material, this article selects EPS expansion of polystyrene board, as well as the popularization and application of the ministry of construction of the wall exterior insulation materials [3]. This paper selected thickness of 20 mm, 30 mm, 40 mm, 50 mm and 60 mm, after transforming the outer wall heat transfer coefficients are shown in table 2.

TABLE2 EXTERNAL WALL THERMAL PARAMETERS

thickness（mm） / name	0	20	30	40	50	60
Heat transfer coefficient	1.37	1.02	0.87	0.79	0.65	0.53

In the other condition is constant, only change the wall under the condition of different thickness of wall in the same heat preservation material, analysis the impacton on the construction of cold and heat treatment of annual accumulative total load by simulation calculation. Results such as3～4.

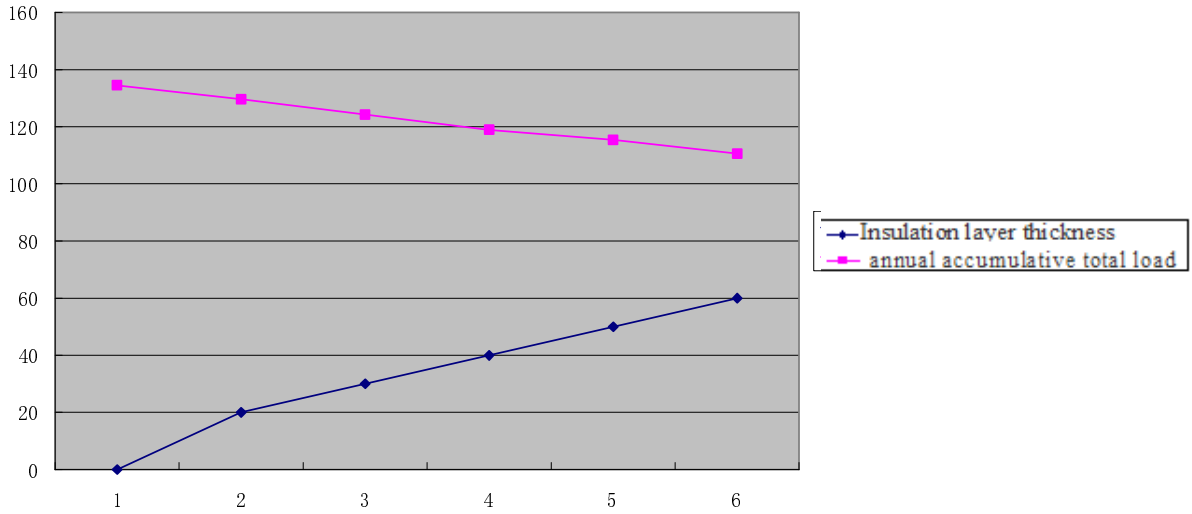

Figure 3 Different thickness of building thermal load

Analysis

Figure 3 shows that both public buildings of the main structure of hollow brick add wall thermal insulation materials have bigger influence on the building thermal load throughout the year, mainly due to lanzhou winter indoor and outdoor temperature difference is bigger, increase the thermal insulation layer thickness in order to reduce the wall heat transfer, heat transfer coefficient can effectively prevent the indoor to outdoor, to improve building thermal treatment of annual accumulative total load effect is obvious. But with the increase of the insulation layer thickness, the effects on the heat load gradually reduce, add 20 mm less insulation heat load effect was most pronounced; Add insulation layer thickness of 20 ~ 40 mm, with thermal insulation layer of heat treatment of annual accumulative total load rate approximately 1.98 x 10^3, and add the insulation layer thickness of 40 ~ 60 mm, with thermal insulation layer of heat treatment of annual accumulative total load rate approximately 1.04 x 10^3, so when a thermal insulation layer thickness of 30 mm or increase the insulation layer thickness to reduce the effect of the building throughout the year the total heat load is not obvious.

4.2 Change the outside window and analysis of impact on building energy consumption

Windows modification measures can be based on the original outside the window with a layer of the window, also can be replaced the original window for energy-saving window, literature [4] to simulate the energy saving effect of different types of Windows, this paper would not be in white.

4.3 Conclusion

Lanzhou city public building exterior wall thermal insulation at least 35 mm thick increase EPS insulation board into a more optimal solution.

Lanzhou city public building retrofit design of the window, in order to double hollow Low radiation low-e glass is the best, the limited economic conditions can consider double hollow glass window.

Keywords: Asphalt Pavement; Plant-mixed Hot Regeneration; Mix Design

Abstract: It is necessary to mend the shattering process and heating technique in order to improve the technology of hot regeneration of plant-mixed old asphalt. The temperature and the reactivation of old asphalt material is supposed to be better controlled as well as the process of mixing and paving roadways as a result of technological improvement. With the reconstruction works of the highway G205 from the Yellow River Bridge to the Liuqiao roundabouts, research of old asphalt mixture has been carried out and all the products turned out to meet the design requirements, according to the results of thimble test, water stability test and tension test in low temperature of Marshall specimen.

Introduction

An increasing number of distresses with varying degrees of damage appear in the high grade roads in China, especially the ones constructed in early 1990s. These appearances severely impact the traffic safety and riding comfort. Pavement maintenance, as a measure tackling the problems, also brings lots of old asphalt materials and, as a result, environmental pollution and economic problems. Therefore, it is significant for the whole society to research on the technology of asphalt regeneration.

The technology, as mentioned above, actually has experienced a huge development since 1980s. In situ cold regeneration, hot regeneration and plant-mixed hot regeneration are the three mature techniques nowadays. Among them, the plant-mixed hot regeneration technology is a kind of practical, flexible and convenient method also with some drawbacks, such as low consumption of materials and inadequate heating of old asphalt. In 2007, the Highway Administration of Binzhou, Shandong invested 800 million yuan to introduce the technology and facilities from Japan and reform the existing craft of plant-mixed hot regeneration. This improvement has been successfully applied in the reconstruction project of G205.

Improvement of technological process

As to reform the asphalt mix plant, more than 800 thousand yuan has been invested to introduce an impact crusher, to crush the old asphalt blocks into a suitable gradation. After crushing the mixture, all the materials should be sieved and stored respectively, in order to restrict the variation of gradation. Unlike the traditional method, asphalt particles should be heated in an indirect downstream furnace with a long combustion chamber (the second dryer) successively. This device makes the materials not exposed to fire and heated by hot air current, effectively prevents the asphalt from burning and aging. The old material gets mixed with the regenerant and after that new asphalt should be put into the mixture. The process above ensures the regeneration of old asphalt in

old material. In comparison with the traditional technology, the demand of old asphalt mixture increases to 30% and the heating temperature becomes 160℃. In the reconstruction project of G205, the whole asphalt pavement (about 12cm) is excavated and recycled for regeneration. The process flowchart shows in Fg.1.

Temperature control

Temperature-control goes throughout the whole process of hot regeneration. In another word, temperature-control, along with the regeneration craft, makes up the core of this technique.Firstly, when heating the old mixture, an appropriate temperature is needed in order to create conditions for further malaxation and reactivation. Since the aging phenomenon under high temperature (>180℃) and oxidation in aerobic environment, the preheat process of old asphalt mixture should be located in a cooler situation. On the other hand, there should be sufficient heat permeating into the mixture while being heated as a result of low electric conductivity of asphalt. Therefore, it is supposed to raise the temperature with a certain heating time or lengthen the time with a certain temperature. Longer heating time lowers the efficiency of construction. The optimum point of temperature and heating time should be identified according to an actual project. Secondly, it's also needed to offer suitable operating temperature for the regeneration of old asphalt and the mixing of new material through temperature control. That is because the asphalt binder in the old material must be in softening state when regenerating. Difference between the temperatures of the old and new material makes it necessary to provide such a heating environment for the sake of final products.At last, as well as the process of paving with new asphalt mixture, the products require an adequate paving temperature in order to obtain enough time for compaction, meeting the design requirements and demands of structure. In addition, cracks could be effectively avoided with less temperature difference.

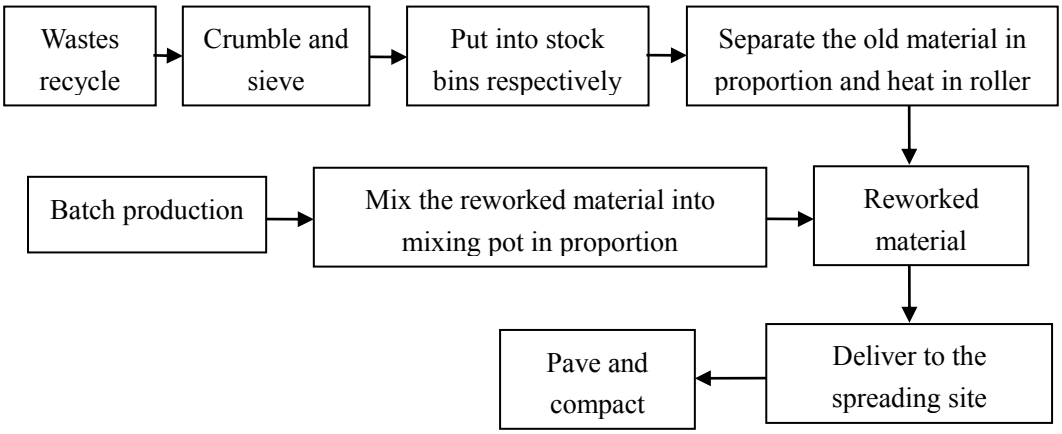

Fig. 1. Flow chart of the technology of Plant-mixed Hot Regeneration

TABLE 1. TEMPERATURE CONTROL REQUIREMENTS OF THERMAL REGENERATION [℃]

procedure	Preheating phase of crumbles		Before delivering	New materials	Recycled materials	Paving temperature
	Temperature at the fan entrance	Storage temperature of crumbles				
requirement	160~180	150~160	>150	>150	>150,<170	>140

Mixture design

The quality of old asphalt materials is the foundation of the whole regeneration project. Thus it is necessary to evaluate these raw materials. The result of the asphalt content test, which was executed at the Highway G205 from the Yellow River bridge to the Liuqiao roundabouts, shows that the content of milling scraps between 10-20mm is 2.9%, and 4.9% for between 0-10mm. The following experiment of sieve test (water washing) with raw materials is listed in Table 2.

TABLE 2. RESULT OF THE SIEVE TEST WITH OLD ASPHALT MIXTURE CRUMBLES

Mesh size [mm]	19	16	13.2	9.5	4.75	2.36	1.18	0.6	0.3	0.15	0.075
Quality percentage through the sieve pore [%]	100	100	100	95	68.8	41.7	30.0	22.2	16.5	12.6	9.4

Grading test was executed in the grading range (Hot regeneration AC-20) recommended by Shandong Transportation Construction Testing Center, according to the experimental results in Table 2. By controlling the major pore sizes (4.75mm; 2.36mm; 0.075mm), the optimal curve could be selected as the target proportion. The proportion is: 10-20mm: 0-10mm: 10-20mm: 5-10mm: 3-5mm: 0-3mm: mineral powder = 10:10:28:23:6:20:3.

Quantity of new asphalt materials was calculated according to the proportion and the content of asphalt in the scrap. After conducting the Marshall test at the asphalt content of 3.5%, 4.0%, 4.5%, 5.0%, 5.5%, the optimum volume was confirmed at 4.4% (3.6% for new asphalt material). Marshall void fraction was 4.6%. Percent voids in mineral aggregate (VMA) was 13.3%. Asphalt saturation was 65.7%. Stability value was 10.16kN. Flow value was 3.14mm. Density was 2.422g/cm^3. All the values above meet the design requirement perfectly.

Performance test for the reclaimed mixture

Performance test for the reclaimed mixture was carried out in the selected asphalt content according to the Marshall test before. High-temperature stability, water stability and low-temperature tension test are the major items. Water stability and anti-rutting performance was evaluated by Hamburg Wheel-tracking Test.

High-temperature stability

The high-temperature stability was evaluated by the rutting test according to the standard JTJ052-200. Dynamic stability of the regenerating specimens forming with the optimal asphalt content was measured in order to evaluate the mixture's anti-rutting performance. As a result, the maximum deflection was 2.34mm, dynamic stability value was 1380 times/mm. The anti-rutting performance of regenerating asphalt mixture turns out to meet the minimum requirements (800times/mm) in this climate zone.

Water stability

Water is able to separate asphalt from mineral aggregate and dissolve soluble compounds, which reduces the strength of the product. The water permeating into the mixture could expand the pavement while after that the pavement is going to shrink again. The circulation above will ultimately crack the pavement.

This project used the freeze-thaw split test for examining the water stability and the result showed that TSR=85.3% (meet the requirement: TSR=75%).

Low-temperature tensile property

When temperature decreases, asphalt mixture should be constricted by the base course and then lead to stress. When the stress exceeds the ultimate tensile strength, cracks occur. Therefore, a great low-temperature crack resistance and deflection performance is necessary for the product.
The tensile property was evaluated under -10℃ and the loading rate of 50mm/min and the result was 2357μm, which meets the requirements in the climate zone.

Hamburg Wheel-tracking Test

Hamburg wheel-tracking test is used for asphalt water stability and anti-rutting performance evaluation.

The test was executed according to the test procedure and the criterion in Texas (50℃, soaking in water). The result evidently showed that the mixture with 20% scraps possesses the best property for both. This result is consistent with the test by the standard of China. An inflection point appears in the mixture with 30% scraps after 12500 times of the test, which means the shortage of new asphalt material leads to the deficiency of asphalt film and weaken the water stability and anti-rutting performance as well.

Conclusion

The technology of plant-mixed hot regeneration has been improved in favor of temperature control and old asphalt mixture recycling. Depending on the practical project of G205 and laboratory tests, the grading curve and proportion of new asphalt was successfully determined and all indexes met the stipulations appropriately. In conclusion, the maximum volume of old asphalt mixture was 20% of the total, amounts to 4.4% of the regenerating material, including 3.6% for new asphalt.

Keywords: Silane coating; Durability; Waterproof; Service life

Abstract: Water could transport aggressive substances such as carbon-dioxide, sulfates and chloride ions in reinforced concrete structures. By penetration, the stability of the whole structure is influenced. This paper deals about waterproof effect and chloride resistance of two kinds of silane coatings, polyethylene-triethoxysilane and triethoxysilane emulsions on concrete substrate along with the mechanism of the hydrophobic action. The results, in terms of visual observations, chloride test and water absorption test, showed that the two silane coatings could reduce the chloride penetration and the water absorption efficiently. The comparison between the two indicates that polyethylene-triethoxysilane penetrates little when applied on the substrate, but it performs better waterproof effect and is more efficient to chloride penetration.

Introduction

Nowadays low durability of concrete structures has become a serious problem. The demand for longer service life leads people to focus more on the function materials. The surface tension in capillary pores in concretes pulls in water because of capillary suction[1’2]. In this process, the penetration of deleterious dissolved substances such as carbon-dioxide, sulfates and chloride ions is allowed and the freeze-thaw damage is harmful to the durability as well. Surface treatment is commonly used to improve the resistance of concrete against the penetration and freeze-thaw damage. In general, protective surface treatment can be attained though surface coating, sealing, and impregnation. [3-9]. As a kind of wonderful protective material, silane materials have good permeability and waterproof effect, they function by penetrating concrete pores, forming a transparent thin layer on the surface of the inner capillary pores of the concrete. Because the pores are left open, the water evaporation of concrete is allowed which is essential for massive concrete structures. The advantages make them an potential protective material as isolators and they are widely used in different engineerings to increase the service life of reinforced concrete structures.

This article is to compare and analyze the waterproof effect, permeability, workability and chloride resistance of two different types of silane coatings for concretes, polyethylene-triethoxysilane and silane emulsions. The corrosion process, the protective effect and the relative mechanisms are mentioned as well.

Mode of Action

Concrete, even of high quality, contains capillaries and micro cracks in nature. In the capillary absorption process is irresistible unless the surface state is changed. Hydrophobic agents always result in chemical reactions on the concrete substrate. Currently, the silanes, silanes polymers and a mixture of these two components are widely used. [10] The small structure of silane materials allows them to easily penetrate in dense substrates. Although the molecular structure is relatively large compared to silanes', silane polymers and silane emulsions also can penetrate in the concrete substrate efficiently. [11-13] In this paper, the silicon-oxygen bonds are relatively quick formed as the silanol groups contact the concrete substrate. The major difference between the radical polymer and emulsion is the carbon chain is formed before the Si-O-Si bonding, so the substrate is protected by a double chain structure, this structure is more durable and the hydrophobic effect still remains. For emulsions, the alkyl-groups bonded to the silicon atom are not linked together and spread out the concrete surface, so the hydrophobic groups can function. The preparation and protective mode of polyethylene-triethoxysilane are illustrated in Fig.1. Through free-radical polymerization, carbon chain is formed, then ethanol molecules are released and silanol structures are formed, polycondensation leads to polysilane, which can be reacted to the hydroxyls on the concrete substrate, forming a stable bond with two surface layers.

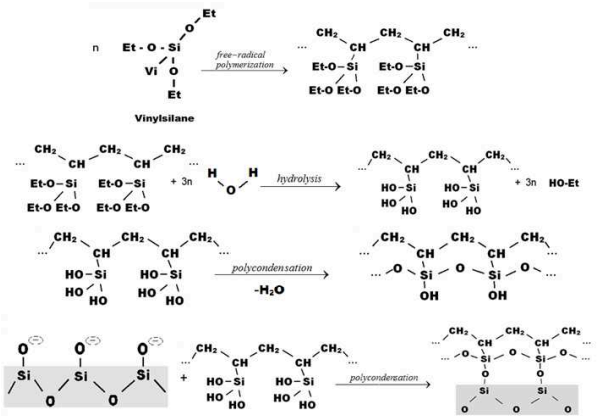

Fig.1: Mechanism Preparation and Reaction of Polyethylene-triethoxysilane on Concrete

It should be noted that, depending on the service conditions, concrete structures absorb liquids (such as water) by capillary forces following the Washburn equation, $\rho=(2\gamma/r_c)\cos\sigma$, where γ represents the liquid surface tension, r_c is the radius of capillary pore, and σ is the contact angle as it is showed in Fig.2. In the condition of constant pore structure and water viscosity, the contact angle is the main factor of capillary force. When the low-surface-tensioned silane coati ng is applied on the concrete structure, it spreads quickly on the concrete and the surface energy of concrete is changed. The low surface energy effect determines that the silane coated concretes show good hydrophobic effect. The molecular attraction between water and the pore walls is decreased and the contact angle becomes more than 90°, ρ becomes negative and the liquid won't fill the pore spontaneously, but remains as sphere water drops on the concrete surface.

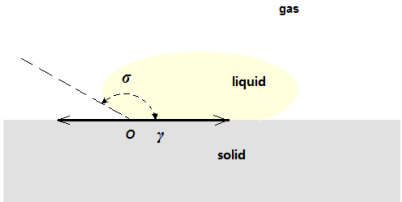

Fig.2: Illustration of Water and Silane Coated Concrete Surface

Experimental Methods and Materials

Materials

Standard concrete (water-cement ratio 0.4 and 0.5) have been prepared as the substrates for the experiments. The compositions of concretes are given in Table.1. According to the amount of mixing water, 1% and 0.8% polycarboxylate superplasticizer were added respectively,

TABLE. 1: CONCRETE COMPOSITION GIVEN AS KG/M^3

Components	Cement	Sand	Gravel	Water	Superplasticizer	W/C
A	380.0	579.0	1269.0	152.0	1%	0.4
B	320.0	653.0	1267.0	160.0	0.8%	0.5

The concretes were added in cubes with an edge length of 100mm and have been cast in steel forms without release agent in order not to disrupt the surface waterproof effect. After 48 hours curing under wet burlap, the cubes were formed and placed in a humid maintenance room (T=20±3℃, RH≥90%) until the age of 14 days. At the age of 14, the cubes were cut into two halves with a diamond saw, then, these half cubes were put back in the maintenance room until the age of 28 days. The half cubes were then dried in a ventilated oven at 50℃ until constant weight had been reached. Then the side surfaces (50×100mm) were sealed with wax, then the blocks were ready for coating, the surface which was in contact with water and steel form during hardening has been coated with polyethylene-triethoxysilane and silane emulsions respectively with the amount of 400 g/m^2. After a static duration of 7 days of penetration, the blocks were ready for the water absorption tests and chloride penetration test. The coated surface has been put in contact with water and the weights were measured in the regular intervals for 72 hours. In the chloride penetration test, the same half cubes have been put in contact in 3% aqueous NaCl solution for 28 days. Then thin layers of concrete have been milled off and the chloride content of collected powder has been determined by means of ion chromatography.

Preparation of Silane Coating

Dicumyl peroxide was selected as initiator. Firstly, vinyl-triethoxysilane was added to the flask, the air was eliminated from the flask by nitrogen, dicumyl peroxide was added into the flask, then the system was heated to 95℃ with stirring speed of 500 r/min until the reaction time for 12 hours, finally the desired polyethylene-triethoxysilane was obtained after cooling. Special attention should be paid to the time and temperature during the synthesis since high degree of polymerization is not required in this study, the synthesis time could be determined by half-life of dicumyl peroxide when the temperature changes.

Two kinds of emulsion were prepared, namely methyl-triethoxysilane emulsion and octyl-triethoxysilane emulsion. Since there is no particular emulsifier for silane, a series of tests have been done to get a steady emulsifier for the silane system. Eventually a compound emulsifier with good emulsification and significant stabilization has been chosen to be the emulsifier for silanes. The mixture contained a proportion of deionized water, silane and a compound emulsifier of Emulsifier S-80, peregal and polyethylene glycol 2000. All these materials were added in the reactor, then stirred evenly with temperature of 55℃and stirring speed of 1200r/min until they were all completely dissolved. Then the emulsion was kept stirring for 5 hours, then the stable emulsion was obtained after cooling. Though the change of proportion, the balance of water, silane and emulsifier assures the emulsion could be function effectively.

Results

Capillary Absorption and Water Repellency

The capillary water absorption by reference concretes and polyethylene-triethoxysilane coated concretes have been determined experimentally. The amount of absorbed water has been plotted. Results are shown in Fig. 3. During the initial phrase of capillary absorption the mass gain can be approximated by a linear function. The inclinations of the straight line is called capillary absorption coefficient.

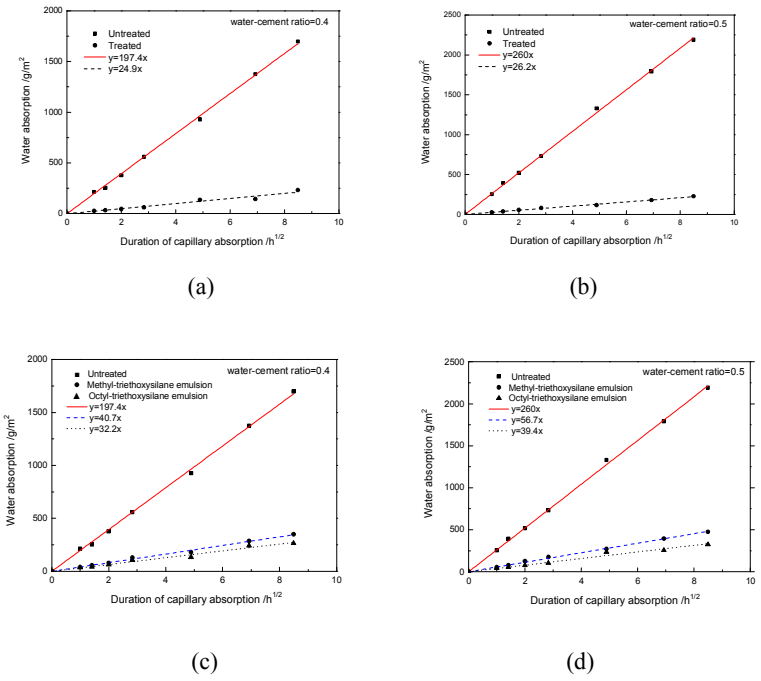

Fig. 3 Effect of Polyethylene-triethoxysilane(a,b) and Silane Emulsion(c,d) on Properties of Concrete Capillary Water Absorption (W/C=0.4(a,c);0.5(b,d))

The results showed in Fig. 3(a,b) indicates that polyethylene-triethoxysilane has significant waterproof effect as concrete coating. When the water-cement ratio is 0.4, the capillary absorption coefficient of the untreated concrete is 197.4 g/(m^2•$h^{0.5}$), but it is only 24.9g/(m^2•$h^{0.5}$) after the coating, the coefficient reduces approximately to 1/8; and when concrete cement ratio is 0.5, the capillary absorption coefficient of the untreated concrete is 260.0g/(m^2•$h^{0.5}$), but it is only 26.2g/(m^2•$h^{0.5}$) after coating, reduces approximately to 1/10. Comparison between the different water-cement ratio concretes with polyethylene-triethoxysilane coating, it is shown that in the case of higher water-cement ratio, the absorption coefficient is relatively larger though, the reduction of water absorption coefficient is great, which indicates that polyethylene-triethoxysilane, as a concrete coating, is more suitable for the waterproof treatment in high water-cement ratio concrete.

The results of two silane emulsions are shown in Fig. 3(c,d). As is shown, when water-cement ratio is 0.4, the capillary water absorption coefficient of methyl-triethoxysilane emulsion treated concrete is 40.7g/(m^2•$h^{0.5}$), and is 32.2g/(m^2•$h^{0.5}$) of octyl-triethoxysilane emulsion treated one. When the water-cement ratio is 0.5, the capillary absorption coefficient increased to 56.7g/(m^2•$h^{0.5}$) of methyl-triethoxysilane emulsion treated concrete, and 39.4g/(m^2•$h^{0.5}$) of octyl-triethoxysilane emulsion treated one. The results indicate that the octyl-triethoxysilane emulsion has better waterproof effect than methyl-triethoxysilane, especially for concrete of W/C=0.5. From another perspective, the change of water-cement ratio had little effect (capillary water absorption coefficient

increased by 18.3%) for the results of octyl-triethoxysilane emulsion, while for methyl triethoxysilane emulsion, the effect is relatively greater (capillary water absorption coefficient increased by 28.2%).

Chloride Penetration

The results of chloride penetration are shown in Fig. 4 of different water-cement ratio (0.4, 0.5) and different silane coatings.

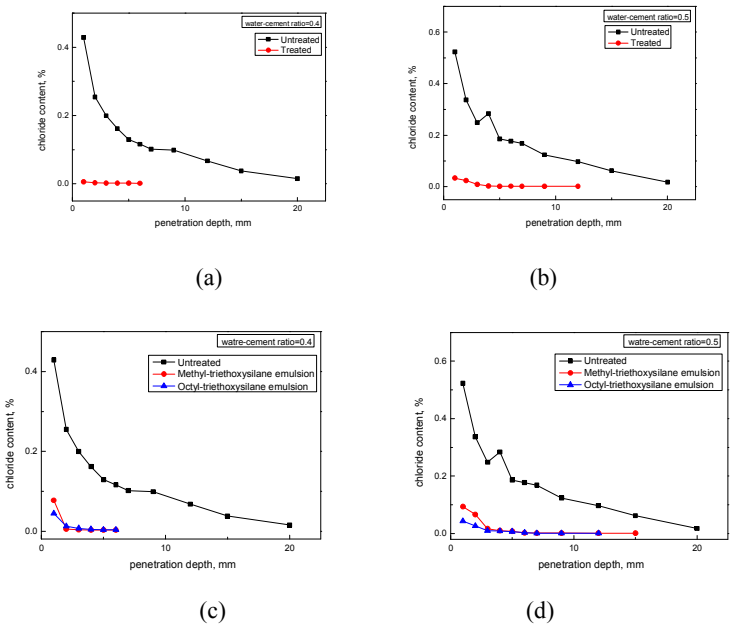

Fig. 4 Effect of Polyethylene-triethoxysilane(a,b) and Silane Emulsion(c,d) on Chloride Penetration in Concrete (Water-cement ratio=0.4(a,c);0.5(b,d)).

It can be seen clearly that silane coatings can efficiently prevent chloride penetration into the concrete when the surface is in contact with NaCl solution. A significant reduction of chloride penetration is observed. As we can see, polyethylene-triethoxysilane has a very good ability to resistance chloride ion invasion. The chloride penetration depth can reach to 20mm of the untreated concrete with high content, but there is little content when the polyethylene-triethoxysilane is applied, especially when the water-cement ratio is 0.4, the content is too low to measure; even when the water-cement ratio is 0.5, the penetration depth of chloride ions is existed in a thin surface layer of only 1~2 mm with a minimum content. After silane emulsions' treatment, the chloride ion content of concrete is still very low, penetration depth is only 1~2mm; when water-cement ratio is 0.5, penetration depth ranges from 1mm to 5mm, but with low content too. In addition, the octyl-triethoxysilane emulsion has better resistance to chloride penetration than the methyl-triethoxysilane emulsion.

Penetration Depth

The results of penetration depth in concrete of all the coatings mentioned above are shown in Table. 2.

TABLE. 2 PENETRATION DEPTH OF SILANE COATING IN CONCRETE(MM)

	Silane coating types		
W/C	Silane coating types	Methyl-triethoxysilane emulsion	Octyl-triethoxysilane emulsion
0.4	1.5	4.7	3.7
0.5	1.3	6.8	5.4

From the table above, it is obvious that penetration depth of different silane coatings varies. When the water-cement ratio is 0.4, methyl-triethoxysilane emulsion has deeper penetration depth of 4.7mm than the others, and 6.8mm when the water-cement ratio is 0.5. The results indicate that methyl-triethoxysilane emulsion has the best penetration among these coatings. Besides, from the penetration depth of 1.5mm and 1.3mm, it could be seen the polyethylene-triethoxysilane of high viscosity is prevented of penetrating into the concrete, which makes it only function in the very thin surface layer of concrete. Moreover, the emulsion penetrate quickly into the substrate, while polyethylene-triethoxysilane seems to have a little penetration difficulty.

Discussion

If the high molecular polyethylene-triethoxysilane is obtained, it can significantly improve the waterproof effect of concrete surface as a protective coating. However, because of the high polymerization degree, its penetration depth is low. The water spray test shows that it is about only 1mm penetration depth of polyethylene-triethoxysilane, which means the protection is effective within very thin depth of concrete. If the upper surface of concrete is pilled off by the external force, the protection can not be guaranteed.

When water-cement ratio gets higher, the porosity of the concrete gets higher too, and this allows silane emulsion to penetrate deeper. In addition, the particle size results in the degree of coating itself penetration into concrete in the same condition. Methyl-triethoxysilane emulsion has deeper penetration depth than the others; this is because the particle size of methyl-triethoxysilane is relatively small compared to octyl-triethoxysilane emulsion. This results in the variation of penetration depth in the same condition. Besides, because of the large molecular structure of polyethylene-triethoxysilane, it is prevented from penetrating into the concrete, which makes it very difficult to get to the inner concrete to function. Although its penetration ability is not desirable, it is still efficient as an isolator to water absorption and chloride penetration.

As higher concrete porosity could allow deeper penetration of silane materials, the resistance ability improves. Therefore, it can be considered that high water-cement ratio concrete is more suitable for surface treatment of concrete.

It can be indicated that the penetration depth of coating is directly related to the molecular structure of the silane material itself. As a macro-characteristic of molecular weight and molecular structure, viscosity could be used to determine the penetration ability of silane coating. From the prepared coatings, it can be observed that the molecule complicated polyethylene-triethoxysilane, which has the highest viscosity, showed the poorest penetration ability. The less viscosity ones, methyl-triethoxysilane emulsion and octyl-triethoxysilane emulsion shows very good penetration ability, so viscosity could be considered as the penetration ability indicator of the silane materials.

Conclusions

Through radical polymerization, stable polyethylene-triethoxysilane of low evaporation rate and high content can be obtained.

Polyethylene-triethoxysilane has significant waterproofing effect. When the water-cement ratio is 0.4, the capillary water absorption coefficient for treated concrete is about 1/8 of the untreated concrete; when the water-cement ratio is 0.5, the capillary water absorption coefficient decreased to 1/10. It is more suitable for the protection of high water-cement ratio concrete.

Polyethylene-triethoxysilane coated concrete has good resistance to chloride intrusion. The chloride ion content in concrete is very low after 28 days' soaking, and depth of chloride ions invasion is only 1~2mm.

The stable silane emulsions could be prepared compounded of Emulsifier S-80, peregal and polyethylene glycol 2000.

The silane emulsion can effectively prevent water from entering into the inner concrete, octyl-triethoxysilane emulsion has better waterproof performance than methyl-triethoxysilane emulsion, but water-cement ratio has great influence on the waterproof ability of the emulsions.

The silane emulsion can obviously resist chloride intrusion. The chloride content of silane emulsion treated concrete is very low with chloride ions only existed in a depth of 1~2mm(W/C=0.4) and 1~5mm(W/C=0.5) of the surface. Octyl-triethoxysilane emulsion's ability to resist chloride ion penetration is better than that of the methyl-triethoxysilane emulsion, because of the involvement of its excellent waterproof effect of the silane itself.

Keywords: Shale gas, Supercritical CO_2, Thickening agents, Polymer, Small molecular, Surfactant

Abstract. Although supercritical CO_2 fracturing has incomparable advantages compared to hydraulic fracturing as a new recreating technology of shale gas reservoir, the application of this technology has been limited by the low viscosity and weak carrying capacity of proppant. It's critical to enhance the viscosity of supercritical CO_2 by adding thickening agents. Thickening agents for supercritical CO_2 that have been studied by researchers mainly contained polymers, small molecular compounds and surfactants. Thickening agents that match with CO_2 are characterized by low cohesive energy density, low polarity, high free volume and Lewis base. It's necessary to study the interaction between thickening agents and CO_2 by molecular simulation to design inexpensive, green thickening agents which could increase the viscosity of supercritical CO_2 remarkably under low concentration.

Introduction

Compared to conventional natural gas reservoirs, shale gas reservoirs are hard to be exploitated. It is uneconomic to exploit shale gas without well stimulation such as fracturing. Hydraulic fracturing technology has been appiled effectively in shale gas exploitation in the United States, but also introduced some significant problems at the same time, such as reservoior damage, large water consumption, and the pollution of groundwater[1]. The shale gas reservoirs in China mainly distribute over unwatered interior area.Compared to the United States, the water sensitivity of the shale gas reservoirs in China is stronger.So hydraulic fracturing can not adapt to the need of massive commercial production[2,3]. Therefore new fracturing technology should be researched in accordance with characteristics of shale gas reservoirs in China.

Supercritical CO_2 fracturing has incomparable advantages compared to hydraulic fracturing [4].However, the application of this technology was limited by it's low viscosity and weak carrying capacity for proppant.One way of overcoming this problem is adding thickening agents to CO2 to increase it's viscosity. If the viscosity of CO_2 is effectively increased,the stimulation results of supercritical CO_2 fracturing could be improved greatly [5].

To track new technology trends and provide reference, the research progress of thickening agents for CO_2 has been introduced and analyzed in three aspects,including polymers, small molecular compounds and surfactants.

Polymer Thickening Agents

Supercritical CO_2 is weak solvent for polar or high-molecular compounds because of it's nonpolarity. Heller *et al.*[7,28] summarized the characters of polymers that dissolved in CO_2, and proposed that polymers that dissolved in CO_2 should be amorphous and atactic.Desimone and Guan[8,9] found that fluoropolymer and siloxane polymer can dissolve in CO_2 at lower pressure than other polymers under certain temperature.

Siloxane Polymer. Bae and Williams *et al.* [10,11] found that poly (dimethylsiloxane) can increase the viscosity of CO_2 effectively with the addition of toluene as cosolvent.Measurement results of capillary viscometer indicated that the lowest dissolving pressure of siloxane polymer in CO_2 decreased after adding cosolvent. The viscosity of CO_2 was increased to 3.48mPa•S,about 90 times

greater than the viscosity of pure CO_2,by adding 6wt% polymer and 20wt% cosolvent at 130F and 2500Psi.This kind of thickening agent wasn't available because of the high cost and the high concentration required.

Fluoropolymer. Fluorinated groups were used to design and synthesize thickening agents for supercritical CO_2 due to their low cohesive energy density and CO_2-philic property. McClain *et al.*[12] reported the breakthrough that polymer can dissolve in CO_2 without cosolvent under proper pressure. They found that poly(1-,1-,dihydroperfluorooty arcylate)-PFOA can dissolve in CO_2 and increase the viscosity of CO_2 apparently. At 323K and 4500Psi, the addition of 6.7wt% PFOA increased the CO_2 viscosity by a factor of 6 relative to pure CO_2.

Enick *et al.*[13,14] synthesized fluoropolyurethane disulfate.The fluoride telechelic ionomer can dissolve in CO_2 without cosolvent, and increase the solution viscosity by 2.7 times at a concentration as low as 4 wt % at 298K and 25MPa.

DeSimone and Guan *et al.*[8,9] found that the addition of 5-10wt% fluorinated acrylate homopolymer increased the CO_2 viscosity by a factor of 3-6. Huang and Xu *et al.*[15,17] synthetized styrene-fluoroacrylate random copolymer as thickening agent and found that this copolymer can increase the viscosity of CO_2 sharply,thickening effect was the best when the molar volume ratio of CO_2-phobic styrene and CO_2-philic fluoroacrylate was 29:71.At 3.4wt% styrene-fluoroacrylate random copolymer in CO_2,the solution viscosity was about 400 times greater than the viscosity of pure CO_2 at the same condition.They attributed the increase of viscosity of CO_2 to π-π stack of CO_2-phobic tyrene aromatic ring functional groups in side chain.

So far, styrene-fluoroacrylate random copolymer was the only thickener that can make the viscosity of CO_2 increase by two orders of magnitude without cosolvent. However, because of the expensive cost and environmental issues, fluoropolymer thickener was just a proof of concept,not a feasible proposal. Therefore,more and more researchers focused attentions on hydrocarbon polymers.

Hydrocarbon Polymer. Heller *et al.*[7,28] evaluated solubility and thickening property of a series of polymers in liquid and supercritical CO_2, and found that polymers that dissolved in CO_2 can't increase CO_2 viscosity effectively. They also synthesized amorphous, random polymer and hydrocarbon telechelic ionomer with ion groups in the end of chain, but those polymers didn't dissolve in CO_2.

Terry *et al.*[18] measured the solubility of a series of organic compounds in supercritical CO_2, and put forward that n-alkanes,isoparaffin below C_{12}, n-alkanol,etherification phenol below C_6, aliphatic carboxylic acid, polyesters below C_9 and aliphatic aldehyde can be miscible with supercritical CO_2. Lancaster *et al.*[19,20] implemented in-situ polymerization through the reaction of organic titanate with organic matrix, but the reaction product was almost insolube in CO_2.

Enick *et al.*[21] researched solubility of some hydrocarbon polymer in CO_2, and found that Poly(vinyl acetate)-PVAc had the highest solubility among those polymers. PVAc can dissolve in CO_2 at 298K and 13.6-67.6Mpa.They attributed CO_2-philic property of PVAc to the the high free volume from ample side chain and interaction between acetate group and CO_2.

Beckman *et al.*[22] found the hydrocarbon polymer that was solube in CO_2 should be composed of two monomer, M1 and M2. M1 provided high flexibility,high free volume and weak solvent/solvent interaction to polymer;M2， which contained lewis base groups,provided favorable solute/solvent interactions between the polymer and CO_2. Proportion adjustment between M1 and M2 can balance solubility and thickening capacity.His work provided direction for the development of hydrocarbon polymer thickening agents.

Small Molecular Compounds

The second strategy that has been explored for CO_2 thickeners is the design of small molecules that have the capability to associate and form viscosity-enhancing networks in solution[23].

Hydrogen Bonding Compound. Enick *et al.*[24,25]synthesized fluorinated aspartate bisureas and ureas for CO_2 thickening. All the samples could dissolve in CO_2 at 7000 Psi and below 373K.

Although both fluoroalkyl and fluoroether were CO_2-philic, fluoroether was more CO_2-philic and therefore was able to impart higher solubility in CO_2 if the other molecular structures are the same.However, all the fluorinated bisureas and ureas couldn't enhance CO_2 viscosity effectively.

In an attempt to design a non-fluorous analog to fluorinated diurea[23,26], CO_2-philic hydrocarbon groups and carbonyl groups were incorprated into the structure. It was hoped that these compounds might also dissolve in CO_2 and self-assemble into long cylinders to thicken CO_2.However,as the molecules began to self-assemble,they came out of solution and formed fibers. Enick *et al.*[24] designed three kinds of triurea compounds which contained polypropylene glycol monomethyl ether tails, dipropylene glycol monomethyl ether tails and di(ethylene glycol)n-butyl ether tails respectively.These compounds did't dissolve in CO_2 at 7000Psi and 373K.

Gullapalli *et al.*[27] reported the gelling result of 12-Hydroxystearic Acid in supercritical CO_2.HAS molecules could interact with each other through hydrogen bond and formed gel networks. At 294-307K and 1800Psi, HSA did't dissolve in CO_2.But HSA could completely dissolve in CO_2 after adding 10% ethyl alcohol or 20% trichloromethane as cosolvent, and formed white fibrous gels. Measuring result of capillary viscometer indicated that the thickening effect of HAS was slight.For example ,the addition of 3wt% HAS and 15% ethyl alcohol just increased CO_2 viscosity by 58% at 307K and 1800Psi.

Organometallic Compound. Heller and coworkers considered organometallic compounds as CO_2 thickeners[28-31].They studied the solubility of organotin fluorides in various solvents including dense CO_2.The trialkyltin fluorides have structure R_3SnF,R represents alkyl, alkylaryl, or aryl group. Because of electronegativity differences between tin and fluorine atoms, there exist dipole moment in these molecules, which causes weak dipole-dipole interactions in neighboring molecules. Even at low concentrations (less than 1wt%), this transient polymer could increase the viscosity of non-polar solvents by several orders of magnitude. For example, tributyltin fluorides could dissolve in n-hexane, and increase solvent viscosity by three orders of magnitude with a concentration of 10g/L. But trialkyltin fluorides could not thicken CO_2 due to their low CO_2 solubility.

Chunmei Shi et al.[32,33] synthesized semi-fluorided trialkyl fluorides to thicken CO_2, and found that CO_2 solubility was enhanced by introducing the fluoroalkyl functionality into the trialkyltin fluoride molecular structure. The solution viscosity was raised by only 3.3 times at a concentration of 4wt% with this low molecular weight compound at 10-18MPa, however.

Surfactants

Appropriate surfactants can assemble and form linear or cylindrical reverse micelle to increase CO_2 viscosity[35]. Consani *et al.*[36] researched more than 130 kinds of commercial surfactants, and found that only a few non-ionic surfactants can dissolve in CO_2. Hoefling et al.[37-41] tried to produce surfactant for supercritical CO_2 by incorprating functional groups ,which were characterized by low solubility parameter, low polarizability or Lewis base,such as fluorinated ether, fluorine and alkyl siloxane,into surfactant tail. Now the researched supercritical CO_2 surfactants mainly were fluorosurfactant, siloxane surfactant and hydrocarbon surfactant.

Fluorosurfactant. Johnston *et al.*[42]produced W/C microemulsion by ammonium carboxylate perfluoropolyether surfactant,and brought surfactant into supercritical CO_2 system successfully.Hoefling *et al.*[37] designed fluoroalkyl surfactants and proved that the fluorinated analogue to AOT surfactant can dissolve in CO_2. Trickett *et al.*[35] replaced hydrocarbon with fluorocarbon and designed fluoroalkyl analogues to AOT,which could form thickening cylindrical micelles in CO_2. At 298K and 35MPa, the addition of 6wt% Na(di-HCF_4), Co(di-HCF_4)$_2$, i(di-HCF_4)$_2$ increased CO_2 viscosity by 15%, 20%,40%,respectively.

Harrison *et al.*[43]reported the first double chain hybrid surfactant comprising of fluororocarbon chain and hydrocarbon chain-F_7H_7.Water up W of 32 could be stabilized in W/C microemulsion at 208K, 26.2 MPa, and surfactant concentration of 1.9 wt%. Cummings and Eastoe et al.[44,45] evaluated

the thickening effect of semi-fluorinated F_7H_4 surfactant in surpercritical CO_2,the addition of 4.4wt% K-F_7H_4, Li-F_7H_4, Na-F_7H_4 increased the viscosity by 10%, 23%, 100% respectively,at 313K and 40MPa.

Siloxane Surfactant. Siloxane surfactant is cheaper than fluorosurfactant,but needs higher critical pressure to form reverse micelle.Fink *et al.*[46] researched siloxane ionic surfactants, and claimed that siloxane analogue to AOT could dissolve in CO_2 when the concentration was below 1wt%,at 338K and below 31MPa. Psathas *et al.*[47] produced W/C or C/W emulsion by segmented copolymer which was made up of CO_2-philic poly (dimethylsiloxane) and CO_2-phobic poly(methyl acrylate) or poly(acrylic acid).

Optimization and adjustment of siloxane surfactant structure could improve it‘s property and lower it’s critical micellar pressure. Fink *et al.*[48] added propyl acetate functional groups to side chain of siloxane oligomers, and found it‘s cloud point pressure fell by 17.2MPa. Rocha et al. [49] found that short and thick tail structure of trisioxanes surfactant could reduce free volume fraction and separate CO_2 and water more efficiently,thus offered stronger capacity of forming reverse micelle in CO_2.

Hydrocarbon Surfactant. Siloxane surfactant and fluorosurfactant aren’t available because of cost and environmental problems.So the researchers tried to develop cheap hydrocarbon surfactants which could dissolve in CO_2. Hutton *et al.*[50] found that AOT could dissolve in CO_2 and form stable reversed microemulsion by adding cosurfactants, such as F-pentanol, alcohol and 1-Pentanol.The required amount of F-pentanol that made a certain amount of AOT dissolve in CO_2 was significantly less than ethanol and 1-Pentanol.Fulton *et al.*[51] found that PFPE-PO_4 and AOT couldn‘t form stable reversed microemulsion lonely，but they could form stable reversed microemulsion when they were mixed together in supercritical CO_2.

Eastoe *et al.*[52,53]provided new idea for the research of hydrocarbon surfactant.By modification of AOT,they produced branching analogue to AOT,AOT3 and AOT4,which contained tertiary butyl in the tail. AOT3 and AOT4 could dissolve in CO_2, but couldn’t form reverse micelle. Whereafter, they designed and synthesized AOK surfactant that contained both tertiary butyl and carbonyl, and proved it can form W/C microemulsion[54]. Ryoo *et al.*[55] researched methylated branched hydrocarbon surfactant,poly(ethylene glycol) 2,6,8-trimethyl-4-nonyl ethers,which had strong capacity of reducing interfacial tension. At 308K-338K and 24MPa, 1.0wt% surfactant and 1.1wt% water,it could form stable microemulsion in CO_2.Methylated branched chains lowered the interaction among tails,which played important role in the formation of microemulsion.

Liu *et al.*[56,57] reported the solubility and phase behavior of alkynol surfactant in supercritical CO_2, such as Dynol-604,Ls-36 and Ls-45.At 208-333K and 26 MPa, Dynol-604 that contained polyether structure could dissolve in supercritical CO_2 and form W/C microemulsion,the hightest solubility was 5wt%.At the same condition,the solubility of Ls-36 in supercritical CO_2 was higher than Ls-45, this was because the ratio of CO_2-philic propenyl oxygen(PO) to CO_2-phobic ethenyl oxygen(EO) was bigger in Ls-36.So we can improve the property of surfactant by adjusting the quantity CO_2-philic groups.

Conclusions

At present, the research of supercritical CO_2 thickeners is still in testing phase.There is no complete and unified theory about this technology. The most significant barrier that continues to impede progress in the development of CO_2-thickening agents is the low solubility of candidate compounds in CO_2.The compounds that dissolve in CO_2 may have properties of low cohesive energy density, low solubilty parameter, low polarizability,high free volume and Lewis base. The solubility may be increased by incorprating functional groups which have above mentioned properties into thickener molecules to promote the interaction with CO_2.Meanwhile, CO_2-phobic functional groups should be incorprated to increase the thickenging capability.

In conclusion, a lot of research work about thickening agents for supercritical CO_2 has been carried out in recent years.The thickening mechanisms and molecular structure design of thickening agents

should be studied in further research.The combination of theory methods such as molecular simulation and experimental means is required to research the thickening mechanism of thickening agents. The ultimate objective should be to produce thickener composed solely of carbon, oxygen and hydrogen that is soluble in supercritical CO_2 and can increase the viscosity of supercritical CO_2 by two orders of magnitude at concentrations less than 1 wt%.

Keywords: Crosslinkers, Gel, Mechanism, Profile Control Agent, plugging

Abstract: This paper is closely related to the crosslinkers used in gelling agents. Both physical crosslinking and chemical crosslinking are discussed. Crosslinkers are added to form intermolecular linkages in between the primary polymer chains to form a stable gel. Both gelling and plugging agents have similar aims---to minimize the permeability of a formation. With the producing water is becoming the big problem, crosslinkers are becoming more important.

Introduction

With the exploitation of the oilfield, excessive water production is a serious issue in maturing oil and gas reservoirs. It leads to additional costs in terms of constructing larger gas/oil separation plants. Additionally, scale formation, emulsion, bacteria and corrosion problems may arise because of high water cut. The oil industry worldwide spends USD billions every year to address the problem of excess water production[1]. Various water-control techniques exist. They include mechanical and chemical means. Among the available chemical water-control techniques, polymer gels have been used widely for lowering water relative permeability while keeping oil relative permeability unaffected through disproportionate permeability reduction or for completely blocking water flow from water-producing zones[2]. For a given well candidate, several factors, including reservoir temperature, lithology, and salinity of the formation water, affect the selection of the required polymer-gel treatment. PAM-based polymers have been used in most water control gels. Depending upon the crosslinker used, gelling systems can be classified into two categories- inorganically and organically crosslinked gels. The term gel can refer to a crosslinked polymer or to a polymer solution that is sufficiently viscous to appear as a gel. This paper is closely related to the crosslinkers used in gelling agents. Both physical crosslinking and chemical crosslinking are discussed.

Physical Crosslinking

Modified PAM which carry negative charges on their backbone can form gels by addition of multivalent positive ions, such as chromium salts. The gel consists of a physical network, which is similar to an ionomer. A single multivalent ion shares a salt with the charges of different polymer chains. The gelation time depends on the molecular weight of the primary polymer, the concentration of ions on the primary polymer chains, and the concentration of the multivalent cations in the solution.

Crosslinker formulations based on iron (III), such as ferric acetylacetonate or ammonium ferric oxalate have been described[3]. 2,4-Pentanedione can adjust the gel strength in such formulations. Zirconium acetylacetonate is also a suitable crosslinker, which have been proposed for physical crosslinking. Chromium (III) salts are used mainly for physical crosslinking. These are not as toxic as chromium(VI) salts, but they are not environmentally desirable compounds, and their use causes additional costs to avoid the contamination of surface waters. Efforts to develop other methods of crosslinking have been therefore undertaken. There are some commercially available salts for physical crosslinking, such as Chromium chloride, Chromium propionate, Chromium acetate, Zirconium lactate, Tetrakis triethanol amine zirconate, Zirconium tartarate and so on.

Chemical Crosslinking

Besides of physical crosslinking, chemical crosslinking systems have been also described. A combination of hydroquinone and hexamethylenetetramine can be used. Sodium bicarbonate in a concentration of 2% serves as buffer and it softens the water by precipitating certain divalent cations present in the sea water. Other chemical crosslinking systems include terephthalaldehyde, terephthalic acid, dihydroxy-naphthalene, glutaric acid, gallic acid, and dibasic esters. The chemical crosslinkings are divided into primary and secondary crosslinkers. Primary crosslinkers are those that produce gels with the polymer, although the gels may be unstable. Secondary crosslinkers stabilize the gels produced by primary crosslinking.

Polyethyleneimine Crosslinker. Polyethyleneimine has been used as anorganic crosslinker for polyacrylamide tertiary butyl acrylate copolymer. Literature reported that polyethyleneimine can also form ringing gels with polyacrylamide (PAM) copolymers in addition to simple PAM homopolymers. For copolymers of AAm, and of AAm and methyl acrylate (5%), polyethyleneimine can be used as crosslinker[4]. Polyethyleneimine has been used as the organic crosslinker to form gels with polyacrylamide tertiary butyl acrylate and mixtures of acrylamide and acrylamido-2-methylpropane sulfonic acid and N,N-dimethyl acrylamide[5]. Someone have reported that polyethyleneimine can form gels with polyacrylamide at room temperature. A recent study has indicated the possibility of crosslinking a simple PAM with polyacrylamide at high temperatures.

Phenol-formaldehyde Type Crosslinkers. The amide groups on PAM can be crosslinked with formaldehyde or a mixture of formaldehyde and phenol, but these small molecules are toxic, and hard to dispose of higher molecular weight reagents, such as hexanal and heptanal, which are not classed as toxic. These are suitable crosslinking agents but they are not sufficiently soluble in water to crosslink normal hydrophilic polymers such as the PAM/polyacrylate copolymer. However, they can be readily solubilized in aqueous solutions by hydrophobically modified PAM polymers, and can then crosslink them. Hexamethylenetetramine hydrolyzes slowly into ammonia and formaldehyde, and can be used in place of formaldehyde[6]. Hexamethylenetetramine with an aminobenzoic acid compound produces better gels than those produced with phenol and formaldehyde, and this gelling system is more environmentally acceptable.

Aluminum Phosphate Ester Salts. Organic liquid gels are used for temporary plugging during fracturing operations. This type of gelling agent permits on-the-fly gelling of hydrocarbons, especially those used in this type of operation. A gel of an organic liquid, such as diesel or crude oil, can be formed using an aluminum phosphate diester in which all of the reagents are free of water and pH-affecting substances. The diester may be prepared by the reaction of a trimester with phosphorous pentoxide to produce a polyphosphate, which is then reacted with an alcohol to produce a phosphate diester. The latter diester is then added to the organic liquid along with a nonaqueous source of aluminum, such as aluminum isopropoxide in diesel oil, to produce the metal phosphate diester. The conditions in the two preceding reaction steps are controlled, in order to provide a gel with good viscosity versus temperature and time characteristics. A similar process involves the reaction of triethyl phosphate and phosphorous pentoxide to form a polyphosphate in an organic solvent. Aluminum sulfate is used as a crosslinker. Hexanol results in hightemperature viscosity of the gel, while maintaining a pumpable viscosity at ambient temperatures.

Aluminum Citrate. Aluminum citrate can be used as a crosslinker for many polymers. In particular, this crosslinker provides a valuable tool for in-depth blockage of highpermeability regions of rock in heterogeneous reservoirs. PHPAs, CMC, polysaccharides, and acrylamido methylpropane sulfonate have been screened in an investigation of the performance of aluminum citrate as a chelate-type crosslinker. The performance of the colloidal dispersion gels depends strongly on the type and the quality of the polymer used. The gels were mixed with the polymers in concentrations at three polymer-to-aluminum ratios. The gels were quantitatively tested 1, 7, 15, and 30days after preparation.

Aluminum Trichloride. Aluminum trichloride is a waste product in chemical industry, and it can react with polymer, form a gel under certain conditions with carbonates and on mixing with alkalies. Laboratory and field tests have shown that aluminum trichloride can be used as a crosslinker agent, for reducing the permeability of water-conducting channels. Because of its low price, and abundant, aluminum trichloride is widely applied in the field.

Crosslinker used in Gelling System

An gelling system has been made of a polymer, a crosslinking agent, a gel stabilizer, and oxygen scavengers. The crosslinking agent is activated at elevated temperatures and the system forms a gel. And portions of oil producing or water injecting reservoir can be temporarily sealed. All the components are selective, so the system does not leave residues that can cause formation damage in the more permeable zones. The polymer is preferably polyacrylamide polymer. The crosslinker are physical crosslinking and chemical crosslinking. Chemical crosslinking used widely at present. The gel stabilizer is ammonium chloride. As known, the most effective oxygen scavengers contained thiourea as the radical transfer agent, isopropyl alcohol as the sacrificial oxidizable alcohol, sodium sulfite as the oxygen scavenger, either tri- or pentachloro- phenol, and a sufficient brine concentration.The initial mixture contains the non-crosslinked polymer chains. When exposed to proper temperatures, typically temperatures of 35-90°C, the crosslinking agent reacts with polymer, and a polymeric gel results.

Special Applications

Chromium acetate-partially hydrolyzed polyacrylamide gel systems have also been applied in fractured reservoirs for conformance control. A wide variety of polymers create flexible gels: polyvinyl alcohol or polyvinyl acetate, PAMs, AAm copolymers, acrylic acid methacrylamide copolymers, and PHPAs, as well as polymethacryl-amides, several natural and modified polysaccharides, lignosulfonates, and polyalkylene oxides[7],[8].

The crosslinking of polysodium 4-styrenesulfonate using Al^{3+} ions to form a gel is described by Keller and Narh. The concentration of the high molecular weight hydrophilic polymers used to form hydrogels is typically in the range 3-10 gl^{-1}, and diverting agents can be added, to improve the penetration of a sand consolidating fluid into areas of lower permeability[9].

Conclusions

From the present study, excessive water production is a serious issue in maturing oil and gas reservoirs. So polymer gels have been used widely for lowering water relative permeability while keeping oil relative permeability unaffected through disproportionate permeability reduction or for completely blocking water flow from water-producing zones. Depending upon the crosslinker used, with the continuous development of environmental protection, the development direction of crosslinking agent is non-toxic, selectivity. Efforts to develop such crosslinkings have been therefore undertaken.

Oil, Water, Slag Three Phases Separation Technology of Heavy Aging Oil

Meng Zheng[1, a]

[1]Drilling & Oil Production Technology Research Institute of Liaohe

Oilfield Company, Petrochina, Panjin, Liaoning, 124010, China

[a]zhengmeng@petrochina.com.cn

Keywords: aging oil, centrifugal separation, dehydration, slag

Abstract. The technology was used for handling heavy aging oil by demulsifier and three phases horizontal scrow centrifuge. Through laboratory and field test, it showed that the water content of the processed aging oil dropped from 50% to 5% below, purity oil recovery rate reached more than 95%, meeting export quality requirements. The technology improved the effective storage capacity of flow station, is of great significance to the safe and steady operation of flow station.

Preface

Usually, The crude oil which is difficult to deal with the existing technical means is known as aging oil, including in the process of oilfield production, oily sewage went through sewage settling tanks, deoiling tanks, flotation tanks and formed a significant number of waste oil; slops in sewage recycling pool; the oil-water emulsion and the falling oil formed during drilling, operation and transportation of crude oil [1 ~ 3]. Aging oil is complicated, the water content is often more than 30%, it is a very stable oil emulsion system [4 ~ 6], so it is difficult to handle using common means of gathering dehydration. Aging oil problem is a worldwide problem because of its complicated components, high viscosity and difficult demulsification. There are typically the following three kinds of approaches to handle aging oil in oil field gathering systems: one is mixing it to crude oil transportation system directly, which make the water content of Oil Transmission overtake standard, affecting the quality of oil products. Two is dropping the water content to10% below, but the existing crude oil dehydration process can't achieve. Three is taking it as tank waste, so it is not selled as qualified goods, of low economic efficiency.

Operating Principle

The separation principle of demulsifier and three phases horizontal scrow centrifuge is based on the demulsifier making oil-water interfacial film damage, when aging oil go into the centrifuge, centrifugal field makes the desity differences of oil, water and solid particles extend a few thousand times, solid phase is settled under the centrifugal force, two kinds of liquid are separated to form two liquid layers to achieve the solid / liquid / liquid three-phase separation and are discharged separately. The feeding and separation process is continuous, closed and automatic.

Results and Discussions

Test oil is the aging oil returned from Liaohe Oilfield Leng Yi flow station sewage treatment system, it is heavy oil, of high viscosity, oil-water density difference is small, emulsion breaking and the centrifugal separation is difficult. The physical property of Leng Yi flow station aging oil is shown in Table 1.

TABLE 1 THE PHYSICAL PROPERTIES OF LENG YI FLOW STATION AGING OIL

Source	Aging oil viscosity （mPa•s，80℃ ）	Crude density （g/ml，80℃ ）	Water content （%）	Solid particles （%）
Leng Yi flow station	428.9	0.9254	50.02	4.37

Considering the peculiarity of aging oil, after research and laborary test, demulsifiers are developed for Liaohe oil field aging oil dehydration. And a series of demulsifier are synthesized for screening. To Leng Yi flow station aging oil, demulsifier A2 is the best from Table 2.Experimental temperature: 90 ℃.

TABLE 2 DEMULSIFIER EVALUATION EXPERIMENT

No.	Drug name	Dosage （ppm）	Dehydration volume（ml,min）

Since 2009, demulsifier and three phases horizontal scrow centrifuge technology, the accumulate treatment amount in Leng Yi flow station, Shu Si flow station, Shu Wu flow station, Huan Er flow station of Liaohe oilfield is 100 thousand ton, the average water content of processed aging oil dropped from around 50% to below 3%.

Taking Leng Yi flow station aging oil as an example, the processing temperature is 90 ℃, dosing of dehydration demulsifier concentration is 600 ppm. Thermochemical settling time is 2 hours. The water content of aging oil before and after processing is shown in Figure 1.

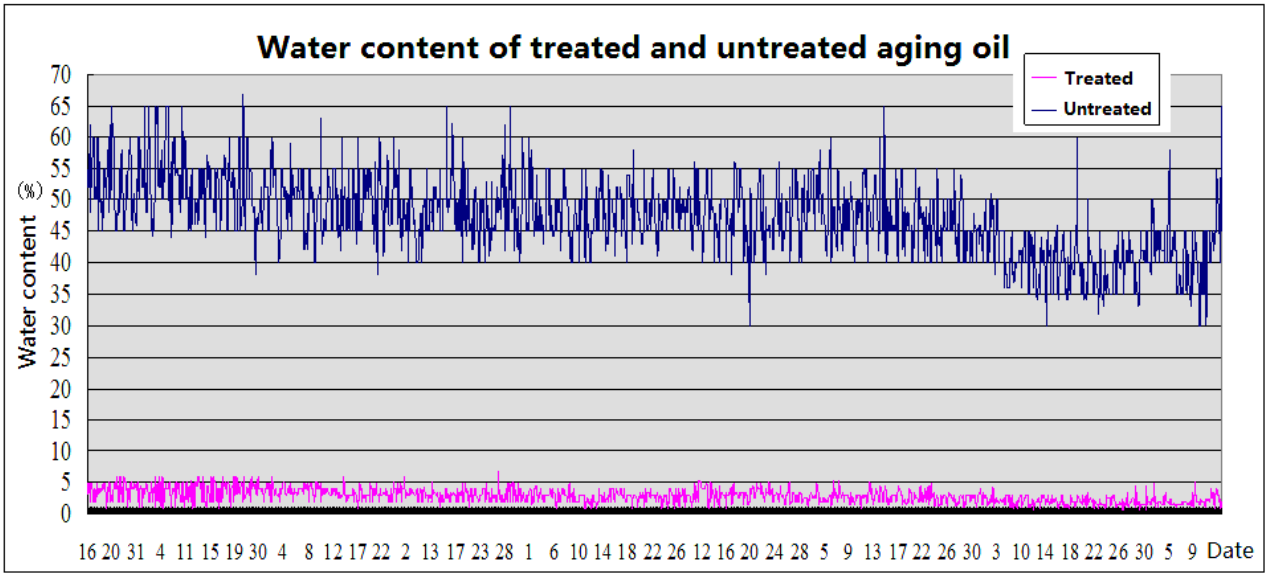

Figure 1 The Water Content Of Treated And Untreated Aging Oil

From the Figure 1, we can see the average water content of processed aging oil dropped from around 50% to below 5%.the aging oil processed by thermochemical settling and centrifuge dewatering, oil and water had been completely separated, achieving the aging oil dehydration, to meet the normal production of Leng Yi flow station requirements.

Conclusions

Demulsifier combined with centrifugal formed processing heavy aging oil technology, which solved the problem of aging oil demulsification and dehydration of heavy oil in Liaohe Oilfield, satisfy the need of production.

The water content of the processed aging oil dropped to 5% below to meet export quality requirements. Previsely unsellable heavy aging oil has reached the required standard , thus improving the rate of oil products and its cost effectiveness.

The technology improved the effective storage capacity of flow station, is of great significance to the safe and steady operation of flow station.

Keywords: Polyacrylamide, Chemical Degradation, Mechanism, Iron ion

Abstract. This paper is closely related to chemical degradation of PAM. The degradation refers to any process that breaks down the molecular structure of macromolecules. The most important degradation pathways in oil recovery applications are oxidation reduction, ironic ions and divalents. The influences of each factor is discussed, and preventive measures are also put forward. It is beneficial to provide the degradation of the polymer, and it can largely improve the utilization rate of PAM.

Introduction

Excessive water production is a serious issue in all oilfield worldwide. It leads to additional costs in terms of constructing larger gas/oil separation plants. Various water control techniques exist. Among the available chemical techniques, polymer flooding has been used for lowering water relative permeability and improving sweep efficiency. The polyacrylamide is widely used, polymer degradation problems could not be ignored. Polymer degradation refers to any process that breaks down the molecular structure of macromolecules. The main degradation pathways in oil recovery applications are chemical, mechanical, and biological[1]. The research is mainly worked on chemical degradation. Chemical degradation refers to the breakdown of polymer molecules, either through short-term attacking by oxygen and iron, or through longer-term attacking to the molecular backbone by processes such as hydrolysis. In other words, polymer chemical stability is mainly controlled by oxidation reduction reactions and hydrolysis.

Oxidation Reduction

For polyacrylamide polymer, the presence of oxygen always leads to oxidative degradation. However, at a low temperature, the effect of dissolved oxygen on HPAM solution viscosity is not significant, and the polymer solution could be stable for a long time. As the temperature increases, even if a small amount of oxygen exists, HPAM solution viscosity quickly decreases with time. For example, the half-lives for a polymer at 50°C, 70°C, and 90°C are respectively 115, 21, and 3 hours.

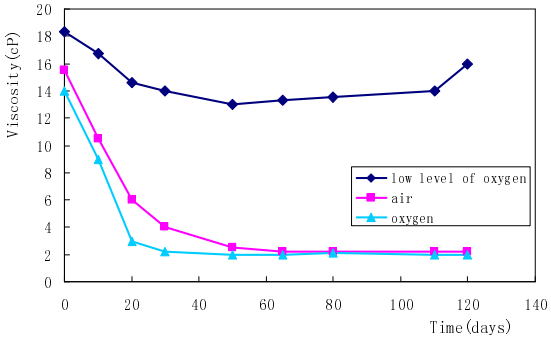

Fig.1 Oxygen's effect on HPAM stability at 90°C

As the oxygen concentration increases, the viscosity decreases faster[2]. Through researching on the chemical stability of PAM solution under simulated field conditions, the rate and extent of polymer degradation were governed mainly by the oxygen content of the solution and temperature. At low oxygen levels (1ppb), the polyacrylamides were stable over 100 days up to 90°C.

The degradation is serious as shown in Figure 1 when air or oxygen presents. When the oxygen was completely consumed, the degradation reaction stopped. This behavior is opposite to the general suspect that after the reaction is initiated by oxygen, it will proceed without further oxygen supply. Therefore, the amount of oxygen in the solution should be minimized by using oxygen scavengers. We can put some methanol or thiourea to protect the polymer from any further oxygen into the solution. The most effective way contained thiourea as the radical transfer agent, isopropyl alcohol as the sacrificial oxidizable alcohol, sodium sulfite as the oxygen scavenger, either tri- or pentachloro-phenol, and a sufficient brine concentration.

Effects of Ironic Ions

In the process of preparing PAM solution, the water usually contains much iron ion. And water conveying pipelines have been used for many years, which coatings have been aging, iron ion soluting in water when it flows through. They are the main source of iron ions. The influence of iron ions are making the PAM degradation, destroying the structure of PAM, lowing the viscosity of PAM[3]. Iron ions mainly exist in the form of Fe^{3+} and Fe^{2+}. Research on the influence of iron ions was carried on.

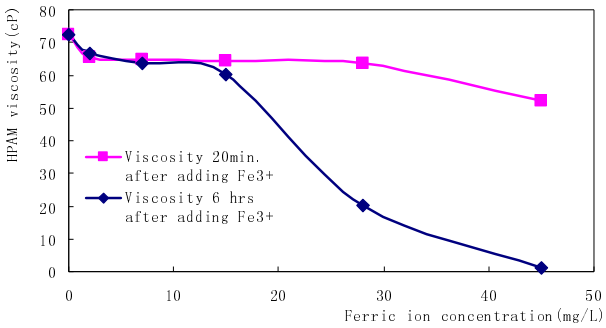

Fig.2 Effect of Fe3+ concentration on HPAM viscosity

Figure 2 shows the ferric ion (Fe^{3+}) effect on an HPAM viscosity at room temperature. The primary viscosity was 72.2 mPa·s. We can see that when the Fe^{3+} concentration was low, the viscosity loss was not significant. The viscosity loss was caused by the salinity effect. When the Fe^{3+} concentration was increasing (>15 mg/L), a brown precipitate was observed. Because the amount of precipitate was little, the viscosity loss was not significant. When the Fe^{3+} concentration was high enough, Fe^{3+} crosslinked with HPAM, and formed a type of gel. The viscosity loss was significant.

In order to give a comparison, we use Fe^{2+} to do the same experiment.

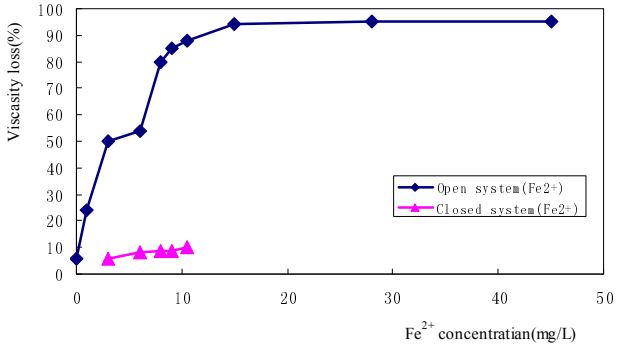

Fig. 3 Effect of Fe2+ concentration on HPAM viscosity

Figure 3 shows the 1200 mg/L HPAM viscosity in a closed system without oxygen at 35°C and 3 hours after adding Fe^{2+}. When Fe^{2+} concentration was lower than 10 mg/L, the viscosity loss was less than 10% owing to the salinity effect. However, when the HPAM solution was put in an open system,

the viscosity was significantly lost, as shown in Figure 3. In the open system, Fe^{2+} was oxidized to Fe^{3+}. We can see that the viscosity loss caused by oxidized Fe^{3+}. The reason is that when Fe^{2+} is oxidized to Fe^{3+}, the free radical O^{2-} is produced. O^{2-} reacts with HPAM to produce peroxide and break the backbones of HPAM. The free radical produced from the reaction further reacts with Fe^{3+} to generate Fe^{2+}, which is further oxidized to produce Fe^{3+} and O^{2-}. A chain reaction occurs, and the polymer viscosity is significantly reduced. In this chain reaction, Fe^{2+} virtually works as a catalyst. Fe^{2+} concentration should be controlled below 0.5 mg/L.

Effect of Temperature

The backbone chain of polymers is quite thermally stable to temperatures as high as 120°C, If there is no oxidative degradation. Indeed, PAM was stable at 90°C for at least 20 months under controlled conditions. At high temperatures, the PAM tend to hydrolyze, therefore increasing the total carboxylate content of the polymer. Thermal stability tests performed showed that the dissolved salts had just a little effect on the hydrolysis rate, and the temperature was the main determining factor. The higher the temperature, the faster the rate of hydrolysis. Hydrolysis was significantly affected by temperature.

In alkaline conditions, initially hydrolysis is fast. As the hydrolysis reaches a certain level, the electrostatic repulsion between carboxyl group and OH- limits further hydrolysis at pH > 13. Finally, hydrolysis is stopped. Therefore, pH has been found to have a minimum effect. At a high temperature, acrylamide is progressively hydrolyzed into acrylic acid; thus, hydrolysis is increased.

In the beginning, hydrolysis increased almost linearly with aging time. After hydrolysis of 44%, the rate of increase slowed down. One of the HPAM characteristics is that hydrolysis quickly increases at high temperatures. Consequently, hydrolysis directly affects HPAM stability. The effect of initial hydrolysis is that the rate of hydrolysis was higher at a higher initial hydrolysis[4]. Therefore, a higher initial hydrolysis is needed in a low-temperature (e.g, 55°C) reservoir so that high viscosity can be quickly reached. In a high-temperature reservoir, the HPAM viscosity near the wellbore will be lower if a polymer with a lower initial hydrolysis is used[5]~[6]. The polymer would be more stable if it is under thermal degradation when the temperature is gradually increased so that the oxygen is consumed at low temperatures.

Divalent Effect

In the low salinities solution, the viscosity of PAM solution increases as hydrolysis increases. In the presence of divalents, the viscosity behavior will be determined largely by the divalent metal ion concentrations. When hydrolysis increases, more acrylic acid produces in the solution. Hydrolyzed polyacrylamides interact with divalent metal cations such as Ca^{2+} and Mg^{2+}. This phenomenon is commonly associated with reduction solution viscosity, which may be formed gels or precipitates.

Through tests we observed the HPAM solution viscosity remained stable until the PAM was hydrolyzed to about 60 mol%, when the Ca^{2+} concentration was below 200 ppm. When the hydrolysis is up to 60~80 mol%, polymer solutions lost almost one half of viscosity. When hydrolysis is limited to less than about 60 mol%, excellent long-term stability can be achieved. Increasing the Ca^{2+} concentration to 500 ppm had a largely effect on viscosity retention.

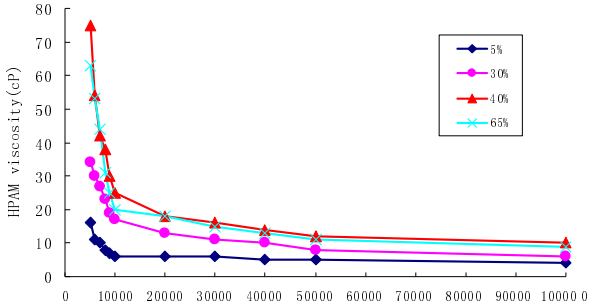

Fig. 4 Effect of CaCl2 concentration on HPAM viscosity with different hydrolysis.

Figures 4 shows an HPAM solution viscosity versus an $CaCl_2$ concentration. In a $CaCl_2$ solution, as the concentration of $CaCl_2$ was increased, the HPAM viscosity decreased rapidly at different levels of hydrolysis. At high $CaCl_2$ concentrations, the viscosity at a lower hydrolysis was higher. The reason is that the divalent Ca^{2+} crosslinks with the acrylic group in HPAM, resulting in coagulation of the molecules. Mg^{2+} is similar but less effect than Ca^{2+}. Davison and Mentzer (1980) found that the precipitation time for the HPAM in seawater at 90°C depended on the primary degree of the polymer's hydrolysis; the higher the initial hydrolysis, the shorter the time before precipitation was observed[7]. Thus, the central role of divalent ions (Ca^{2+} and Mg^{2+}) and the primary degree of hydrolysis of the PAM are known to affect and limit the stability of HPAM in solution at elevated temperatures, even under anaerobic conditions.

Conclusions

From the present research, polymer degradation is serious issue. It refers to any process in oil recovery applications. Chemical degradation refers to the breakdown of polymer molecules. In other words, polymer chemical stability is mainly controlled by oxidation reduction, ironic ions and divalents. They can easily destroy the structure of PAM, or interact with the acrylic group in HPAM. The solution viscosity is largely reducted. Both of them affect HPAM stability.

Keywords: case-based reasoning; drilling speed; drilling parameter; optimization

Abstract: In the view of the complex influence factor, simplified research method and structural or partial structural application model a drilling parameter selection optimization method based on case-based reasoning is provided in this paper. The goal of the research is to build up a drilling parameter selection optimization method which has great applicability. Based on the field drilling data and parameters a case base is built up. Afterward data discovery is used to deal with the case selection problem and select case from case base. Combining with field situation, drilling parameters selection is optimized and drilling speed could be predicted.

Introduction

Drilling parameter optimization called optimized drilling. Optimized drilling is a drilling technology in jet drilling and balance drilling developed. Is the combination of the optimization mathematical theory and the drilling of scientific experiments. Is the study of drilling pressure, rotating speed, hydraulic parameters, drilling combination drilling parameters and mechanical drilling rate, and so on. The increase rate of penetration is learned for reducing the cost and increasing economic benefits[1]. However, In the drilling operation, affect the rate of penetration is very complex, factors affecting is very various. Although the drilling rate equation was established, but practicality is not strong, General equation is not necessarily on a different block, it is difficult to use the exact model to simulate and forecast. Because Case-based Reasoning in processing semi-structured and unstructured problems have excellent ability, thus the drilling parameter optimization model based on Case-based Reasoning for drilling rate prediction is established having realistic and important meaning.

In this paper, drilling parameter optimization is researched using the theory of Case-based Reasoning. Case-based Reasoning will achieve two functions in the drilling parameter optimization by two aspects of research work. The first function is that according to drilling parameters of the case base for Haita oilfield data analysis, using the theory of Case-based Reasoning for drilling parameter optimization. It play a direction role for drilling parameter optimization and drilling rate forecasting in the area. The second function, according to drilling parameters data case base of Haita oilfield being used by the drilling parameters, the seismic data and logging data of, using the

theory of Case-based Reasoning, according to the geological characteristics of block and regional similarities were simulated and matched, for different strata in different areas of the drilling parameter optimization and forecasting of rate of penetration, the new blocks has a applicability.

Based on Case-based Reasoning Drilling Parameter Optimization Model

The Basic Principle of Drilling Parameter Optimization Based on CBR

Drilling parameter optimization based on Case-based Reasoning is a kind of use in the past a lot of actual drilling parameters to establish the parameters of case base, dig out many useful information and knowledge, based on previous actual drilling parameters to analysis and forecast the trend of the drilling rate of penetration under the new situation and the new conditions, so as to improve the rate of penetration and save drilling cost, increase the economic benefits. The basic idea is: in the solution of the problem, first of all, retrieve the most similar cases with the issue in the case base for drilling parameters, if we can find an exact match, as solving the output, if can't find, a similar case be seek and be revised according to the requirements of the problem, and the correction results be saved in the case base. Fig.1 is drilling parameter optimization system structure diagram base on the example of reasoning[2,3].

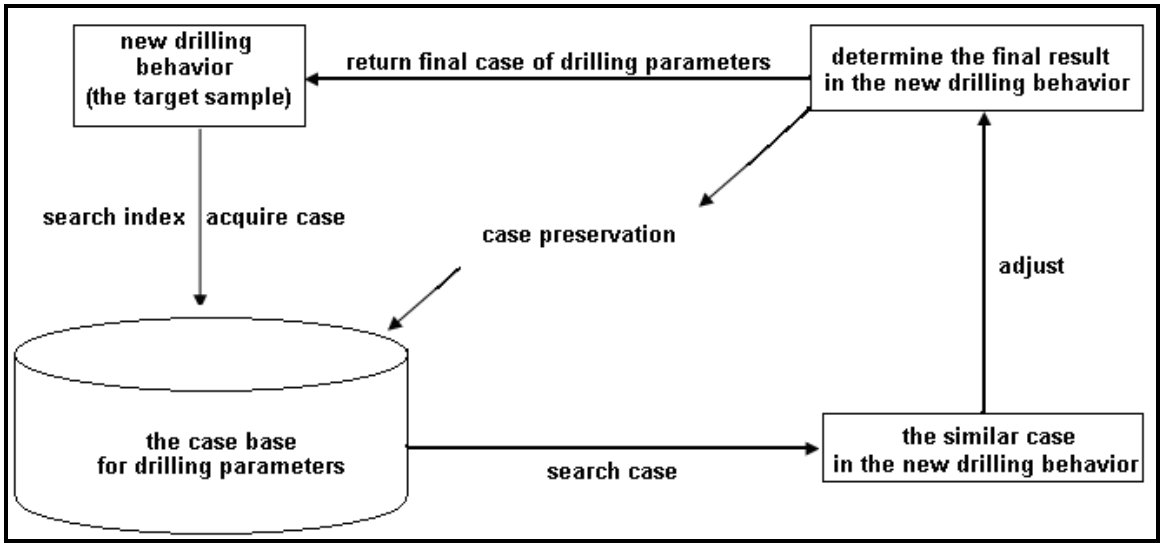

Fig.1 Drilling Parameter Optimization System Structure Diagram Base On Case-Based Reasoning

The Pretreatment of the Drilling Data

In Case-based Reasoning, the establishment of drilling parameters of the case base is the primary work. In the process of the construction of case base, a reasonable and consistent case representation method is indispensable. an appropriate expression way of he scenario, the answer, the result is a question of fundamental importance of construct a sample based on Case-based Reasoning. In drilling parameter optimization system based on Case-based Reasoning, using object-oriented technology show affect the penetration rate of drilling parameters, the object of each instance and background database record is one-to-one correspondence and them will be Dynamic Structured by the system in running[4].

Because of the complexity and accuracy of the actual drilling parameters, the actual drilling data will be calculated by Case-based Reasoning model. Firstly, make the data into use the data of the model can make. Drilling parameters of the original data include stratigraphic composition description, the drilling strata, segment, bit type and bit size, footage, rate of penetration, penetration time, actual drilling time, round trip time, drilling pressure, rotating speed ,

displacement, the stand pipe pressure, the pressure drop of the bit, annular pressure loss, impact, injection speed, bit specific hydraulic horsepower, upward velocity, tooth wear, diameter wear and bearing wear, etc. The formation components described are based on textual descriptions, so for example reasoning model application has the certain difficulty. This paper prepared to take lithological types description into a comparative value of digital type description or letters type description. The other drilling parameters are a digital type data, So as long as the actual drilling data is dealt for unification and tidy.

The Establishment of the Drilling Parameters Case Base

Case base on Case-based Reasoning plays a decisive role, the realization of the case base sample directly affect the success of reasoning. Drilling parameter optimization method based on Case-based Reasoning, therefore, is to establish the priorities for drilling parameters of case base[5,6]. Processing method according to the actual drilling parameters and requirements, turn drilling parameters, establish drilling parameters case base suitable for Case-based Reasoning.

The drilling parameters case base is established by SQL server in this study. The case base have some function is more significant which in addition to the drilling parameters input, find and keep the basic functions, such as network sharing, it can directly share the enterprise database and remote calls. Using the Delphi form software platform, for case base calls, implemented with platform operation ability and visual oriented practical examples based on case-based reasoning of drilling parameter optimization software.

Similarity Measure and Retrieval Technology of Drilling Parameter Optimization System

Assumptions, n set of drilling parameter data, constitute n dimension data, one group of drilling parameter data is X, X characteristic parameters——drilling parameters of the stratigraphic composition description written by X_1, drill for drilling period by X_2, interval remember to X_3, type of bit for X_4. and so on, Mathematical expressions has the following form, $X=\{X_1,X_2,\cdots,X_n\}, X_i(1\le i\le n)$ is characteristic value, W_i is weight. X is a point of n dimension characteristic space $D=(D_1,D_2,\cdots,D_n)$, $X_i\in D_i$.

$$Dist(X,Y)=\left(\sum_{i=1}^{n}D(X_i,Y_i)^r\right)^{1/r} \tag{1}$$

$$D(X_i,Y_i)=\begin{cases}|X_i-Y_i| & \text{If } D_i \text{ is continuous}\\ 0 & \text{If } D_i \text{ is discrete, and } X_i=Y_i\\ 1 & \text{If } D_i \text{ is discrete, and } X_i\neq Y_i\end{cases} \tag{2}$$

When r is equal to 2,and $Dis(X,Y)$ is Euler distance.The similarity measure function between the goal case of this model and the source case using euler distance.

$$Sim(X,Y)=1-Dist(X,Y)=1-\sqrt{\sum_{i=1}^{n}D(X_i,Y_i)^2}\ (Dist(X,Y)\in[0,1]) \tag{3}$$

$$Sim(X,Y)=\frac{1}{1+Dist(X,Y)}=\frac{1}{1+\sqrt{\sum_{i=1}^{n}D(X_i,Y_i)^2}}\left(Dist(X,Y)\in[0,\infty)\right) \quad (4)$$

Although examples based on the reasoning of drilling parameter optimization algorithm of comparability measurement function has been established, but the sample reasoning retrieval strategy is also very important. An example of how to retrieve the as less as possible, an example of retrieved as far as possible with the target sample related or similar is the key retrieval examples. This system adopts the nearest neighbor retrieval method and retrieval method based on knowledge, the core of the nearest neighbor retrieval method is to calculate the similarity between example, identify one or more examples of the maximum similarity retrieval results for its. And deep retrieval method based on knowledge is according to the characteristics of attribute importance in question given properties of different weights, usually combined with the nearest neighbor method is used.

The Drilling Parameter Optimization System Based on Case-based Reasoning Correction Technology

The old paradigm which is similar to the drilling parameter optimization problem is found and then the sample drilling parameters is corrected if there is no old paradigm matched the new sample completely in drilling parameter optimization system based on model reasoning[9]. Correction technique is the key technology of drilling parameter optimization system, it affects directly ,the success of drilling parameter optimization system based on model reasoning, but it is difficult to access, correct knowledge compared with capture, because its lack of methodology ,which is accessed and used rules in the correction techniques.

This system takes advantage of a repeat method based on the example, this method records the process of solving and preserves, drilling parameters as the instance then reasoning new problems based on the corrected instance, and complete correction of the new problems of drilling parameter correction phase.

Application

122 Wells Field data is collected for the establishment of case base. The Field application is carried out according to the drilling parameter optimization model based on Case-based Reasoning. The haita oilfield drilling parameter optimization results are obtained. The table 1 is the drilling parameter optimization results.

TABLE1 DRILLING PARAMETER OPTIMIZATION RESULTS

block	Formation	rotate speed of the optimization	WOB of the optimization	delivery capacity
19 block	U.Zuun bayan	135~170	150~170	29~32
	L.Zuun bayan	130~155	155~180	28~32
21 block	U.Zuun bayan	135~172	150~175	29~32
	L.Zuun bayan	130~154	155~178	29~32
Wudong block	U.Zuun bayan	140~185	150~182	28~32
	L.Zuun bayan	130~162	175~192	28~32
Bei block	U.Zuun bayan	140~181	150~188	29~32
	L.Zuun bayan	130~165	175~200	28~32

Through the field test, the drilling speed after parameter optimization is very good. The average rate of penetration is 15.32 m/h in 2011, the average rate of penetration after optimization is 21.35 m/h in 2012, after optimizing the mechanical drilling rate increased by 39.36% than before optimization.

Conclusions

(1) The drilling parameter optimization based on Case-based Reasoning optimize the drilling parameter from a unique Angle, has the advantages of simulate human reasoning process, has excellent ability in the treatment of the semi-structured and unstructured problems.

(2) The characteristics of case base organization, sample selection and retrieval, similarity measure method and the correction of sample characteristics directly affect the quality and quantity of drilling parameters, and directly affect the credibility and fidelity of drilling parameter optimization.

(3) The drilling parameter optimization method based on Case-based Reasoning is built on the basis of case base. the accuracy of the sample must be improved for the preferences credibility.

Abstract. According to the Evaluation and Expression of Uncertainty in Measurements, the author establishes the mathematical model for measuring the purity of hydrogen in transformer oil by means of Gas Chromatography. Meanwhile the author analyses resources of uncertainty and deduces formulas of uncertainty measurement. By calculating uncertainties of the components, the author obtains the synthesis uncertainty.

Introduction

As one of the important equipments in the power industry, the transformer plays a critical role in economical power transportation and flexible power distribution. As an effective method to maintain and monitor the transformer, Gas chromatography, a way of on-line analyzing Hydrogen content dissolved in transformer oil and deducing potential problems in the transformer has been widely applied and developed.

The Process of Test

Instruments and Materials

The instruments and materials include GC-900AD Gas-Phase chromatographic instrument produced by Zhongfen Instrument, Chromatography column filled with Hayesep-D, Hayesep-S, GDX-502 filling materials, Electric six-way valve Port produced by VICI Corporation SWISS, TGS813 Semiconductor gas transducer produced by Figaro JAPAN, High-purity air, High-purity oxygen and High-purity nitrogen (Nominal value is 99.9%±0.05%).

Chromatographic Conditions

Head pressure: 10MPa; Column Temperature: 40℃initially, 10minites later, raise to 60℃at speed of 5℃/min; Carrier Gas Flow Rate: 10ml/min; Injection Volume: 1ml in quantitative tube.

Procedures

According to GB/T 5274-2008 Gas Analysis - Preparation of Calibration Standard Gas Mixture, H2 is the raw material made of high-purity H2, N2. H2 are prepared at the purity of 21, 66, 142, 203, ppm respectively.

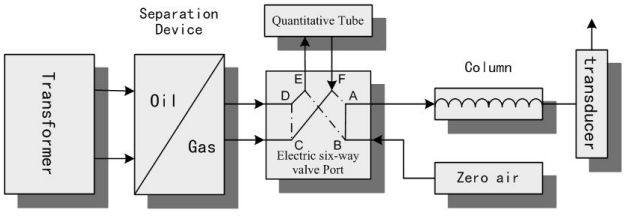

Fig. 1. Flow chart of oil and gas analysis

Evaluation of Uncertainty

According to the experiment methodology, experiment process and Modern Error Theory, The uncertainty of H2 purity is tested by Gas Chromatography and has the following uncertain resources:

(1) Uncertainty caused by quantitative tube capacity error
(2) Uncertainty caused by repetitive operation
(3) Uncertainty caused by standard curve regression
(4) Uncertainty caused by measuring the standard gas

Uncertainty Caused by Quantitative Tube Capacity Error

The author uses SL1KUW stainless quantitative tube made from VICI, Swiss. The standard error is ±0.05ml according to the manufacturer. This uncertainty is classified into B-level uncertainty.

The standard uncertainty is in (1).

$$u(v)=\frac{0.05}{\sqrt{3}}=0.0289 \tag{1}$$

Relative uncertainty is in (2).

$$u(V)=\frac{u(v)}{V}=\frac{0.0289}{1}=0.0289 \tag{2}$$

Standard uncertainty is in (3).

$$u(v)=\frac{0.05}{\sqrt{3}}=0.0289 \tag{3}$$

Relative uncertainty is in (4).

$$u(V)=\frac{u(v)}{V}=\frac{0.0289}{1}=0.0289 \tag{4}$$

Uncertainty Caused by Repetitive Operation

Due to the variety of stuff's familiarity with the operation and instability of the instruments, uncertainty caused by repetitive operation belongs to A-level uncertainty. Table-1 is the H2 purity after repetitive tests.

TABLE I. Repetitive Tests（unit: ppm）

No.	1	2	3	4	5	6	7
Purity of H_2	62.8	62.9	62.9	62.8	62.9	62.8	62.8

Standard error is in (5).

$$s(m)=\sqrt{\frac{\sum_{i=1}^{n}(x_i-\bar{x})^2}{n-1}}=0.000251 \tag{5}$$

Standard uncertainty is in (6).

$$u(m)=\frac{s}{\sqrt{n}}=\frac{0.000251}{2.646}=0.0000945 \tag{6}$$

Relative uncertainty is in (7).

$$u(M)=\frac{u(m)}{\bar{\rho}}=\frac{0.0000945}{0.998957}=0.0000946 \tag{7}$$

Uncertainty Caused by Standard Curve Regression

The H2 with 9 different Purities are tested for four times by Gas chromatography for the maxim of the gas purity, and the results are bellow after 36(n) times of testing.

TABLE II. The result of repetitive testing

H_2 purity in standard gas /ppm	Maxim No.1	Maxim No.2	Maxim No.3	Maxim No.4	AVERAGE Maxim
21	5.2401	5.5960	5.4524	5.1773	5.3664
66	8.5025	8.8574	8.7661	8.6428	8.6922
142	15.9825	16.2332	15.6636	15.2033	15.7706
203	24.0192	24.1774	25.8811	26.1741	25.0629

Suppose the mathematic model of linear fitting standard curve is

Where

H_i ——The maximum of standard gas i

ρ_i ——Purity of H2 in gas i

And the slope of the fitting line is in (8).

$$k=\frac{S_{xy}}{S_{xx}}=\frac{\sum_{i=1}^{36}(\rho_i-\overline{\rho})(H_i-\overline{H})}{\sum_{i=1}^{36}(\rho_i-\overline{\rho})^2}=\frac{1994743}{3557768}=0.0561 \tag{8}$$

Intercept b is in (9).

$$b=\overline{H}-k\cdot\overline{\rho}=30.2665-0.056\times374=9.2973 \tag{9}$$

So the linear fitting regression curve is in (10).

$$H_i=0.0561\rho_i+9.2973 \tag{10}$$

The standard deviation of H2 purity is in (11).

$$s(H)=\sqrt{\frac{\sum_{i=1}^{n}v_i^2}{n-2}}=\sqrt{\frac{\sum_{i=1}^{n}(H_i-k\rho_i-b)}{n-2}}=4.0431 \tag{11}$$

Now certain transformer oil is under test for 3 times and its H2 purity is 68.4 ppm. Its standard uncertainty is in (12).

$$\begin{aligned}u(x)&=\frac{s(H)}{k}\sqrt{\frac{1}{p}+\frac{1}{n}+\frac{(\rho_0-\overline{\rho})^2}{S_{xx}}}\\&=\frac{4.0431}{0.0561}\times\sqrt{\frac{1}{3}+\frac{1}{36}+\frac{(68.4-374)^2}{3557768}}\\&=44.8549\end{aligned} \tag{12}$$

And relative uncertainty is in (13).

$$u(X)=\frac{u(x)}{\rho_0}=\frac{44.8549}{68.4}=0.6558 \tag{13}$$

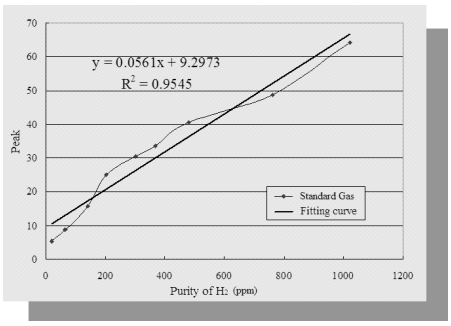

Fig. 2. Linear regression fitting curve.

Uncertainty Caused by Measuring Standard Gas

The gas bottle should be cleaned with N2 and vacuum pressure should reach 0.1kPa before it is filled. Retained N2 quantity can be calculated by (14).

$$m = \frac{x_i \cdot p_f \cdot V_{cyl} \cdot M_i}{R \cdot T \cdot Z_f} \tag{14}$$

Where

mi ——quantity of component i in mixture gas, in grams

xi ——expected concentration of component i in mixture gas, in ppm

T ——environmental temperature, in K

Zf ——compressibility at T and pf

The quantity of retained N2 is in (15).

$$m = \frac{x_i \cdot p_f \cdot V_{cyl} \cdot M_i}{R \cdot T \cdot Z_f} = \frac{0.9 \times 1.04 \times 10^{5} \times 5 \times 10^{-6}}{294 \times 8 \times 1} = 5.3mg \tag{15}$$

Because of even distribution of retained gas quantity, standard uncertainty is in (16).

$$u_r = \frac{5.3}{1.732} = 3.06005 \tag{16}$$

Comparative uncertainty is in (17).

$$u_R = \frac{u_R}{M} = \frac{3.06005}{773.5} = 0.00396 \tag{17}$$

Combined Uncertainty

Relatively combined uncertainty of H2 concentration in transformer oil is in (18).

$$u = \sqrt{u^2(V) + u^2(M) + u^2(X) + u^2{}_M + u^2{}_R} = 0.6564 \tag{18}$$

Conclusion

Relative synthesis uncertainty of H2 purity in oil transformer is 0.6564, tested by Gas chromatography, and H2 purity in a certain type of transformer oil is 62.89 ppm, and Relative synthesis uncertainty is 0.6564.

Keywords: zirconium powder；plasma-atomic emission spectrometer；dissolution；zirconium content

Abstract: Instrument analysis method is used in this experiment, which detecting the zirconium content of zirconium powder by using plasma-atomic emission spectrometer. In this experiment, the instrumental detective conditions were determined, and analyzed several main factors affecting the experimental results, concluded the effects of temperature, hydrofluoric acid and deionized water on dissolving zirconium powder, summarized the method to detect zirconium powder content directly by ICP.

Introduction

Zirconium and zirconium alloys possess outstanding nuclear performance, beside it have excellent corrosion resistance and mechanical performance, have been applied extensively in civilian area of energy, petroleum, chemical industry, pharmacy, medical equipments and light industry and so on, also as an important additional element of high property magnesium alloys [1], the additive of medium temperature nuclear materials [2], armament industry and aerospace new materials [3]. Zirconium and zirconium alloys have been praised as "one of the most promising materials in 21 century". Zirconium powder is the important product of zirconium series products, has great surface free energy and strong liveness. For different areas, the demand of zirconium content is also different. As alloying additive and powder metallurgy, etc, the zirconium content should more than 97%; as fireworks and ordnance industry, etc, the zirconium content should more than 90%; as nuclear industry, the zirconium content should more than 99% [4-6]. As a result of the higher zirconium content in general products, it will have a bigger deviation by chemical analysis method, and detect zirconium content is different, mainly detect impurities content in zirconium powder in all kinds of documents, so in order to detect zirconium content quickly and conveniently, deciding to use ICP-AES to detect zirconium content directly in this paper through continuous experiments.

In this experiment, mainly detect zirconium powder that produced by metal calcium deoxidate zirconium dioxide, the content of zirconium powder is more than 97%.

Experiment

Main reagents

Hydrofluoric acid; nitric acid; standard zirconium reagent. The reagents in this experiment are AR, water is secondary distilled deionized water（ultrapure water）. The standard sample solutions which content 0.1 mg/L，1 mg/L，10 mg/L，100 mg/L were prepared for build work curve.

Experimental process

Taking 0.01g zirconium powder accurately into 100 ml beaker which made by teflon, then add 10 ml nitric acid to ensure the sample fully soaked in acid, heating solution until about 60 ℃ and shake beaker gently to make sure uniformity of temperature, then add 4 ml hydrofluoric acid slowly by using one-time dropper, the reaction is drastic and solution turns yellow with smoke, when the color up-to the most yellow, add 15 ml deionized water to control reacting rate in order to getting more thorough of the reaction, and the standard volume of deionized water is till to the color of solution become limpid[7]. Until the reaction is complete, adjusting temperature of electric furnace to about 100 ℃ for evaporate and concentrate, when the solution volume become 2-3 ml, then stop heat, chill, finally allow the solution into 100 ml volumetric flask through constant volume.

Inductively coupled plasma atomic emission spectrometry (Prodigy XP, Lee man Company, USA) was used to detect.

Work conditions of instrument:

RF 1:1.2 kw，high frequency generator: 40.68 MHz, cooling air: 18 LPM, atomizer: 35 PST, observation way: bidi-rection, optical system: high resolution echelle, wavelength range: 175-900 nm, detector temperature: - 16 ℃, lifting capacity of sample: 1.5 ml/min, integral time: 20 s.

Firstly, according to work conditions of instrument, establishing proper work curve by using standard sample of zirconium which prepared already, spectral line of zirconium generally choose in 339.198 nm, then shake un-test solution until uniform and detect by instrument.

Results and analysis

This experiment is trace experiment, some microelements in acid and some trace elements in deionized water are influential to the experimental results, so every experiment requires blank experiment, try to reduce the effects of dissolving process. Generally, the main impurities in zirconium powder which made by metal calcium thermal reduction is calcium, the emission line of calcium is 317.933 nm, while detecting the elements of different emission signal values has less effects by using plasma atomic emission spectrometer[8]. Detective results and influence factors as shown in the Tab. 1.

Tab. 1. Detective results of zirconium powder under different conditions

Sample weight/g	Temperature/℃	HNO_3: HF/ml	Deionized water/ml	Concentration/ppm	Zirconium content/%
0.0112				71.2383	63.61
0.0108				75.7520	70.15
0.0103	30	6:3	10	62.8229	60.99
0.0100				51.4422	51.44
0.0104				52.3679	50.35
0.0101				82.5064	81.68
0.0110				83.9743	76.34
0.0100	60-70	6:3	10	89.2372	89.24
0.0103				71.4831	72.65
0.0113				84.1253	74.45
0.0100				98.0280	98.02
0.0103				100.8654	97.93
0.0106	60-70	10:4	15	104.1725	98.27
0.0099				97.3071	98.29
0.0113				110.9729	98.21

The average of detective sample content in this study is 98.144%, a same batch of samples will be send to national nonferrous metals and electronic materials analysis inspection center (assay is detect the content of impurities in zirconium powder) , the zirconium content was 97.6573%, and the error of the test results which using this instrument is less than 0.5%, detective error of overall content is between plus or minus 0.4%, basically meet the test requirements.

The influence of solution temperature on the test results

ICP-AES plasma test method belongs to trace test, so pay attention to eliminate all influential factors for the experiment is needed. During the process of sample dissolution, founding that the temperature has much effects on the dissolution process, dissolving in the condition that around 30 ℃,for the rest of the solution, we can obviously see some residues have not been dissolved completely in the bottom of the beaker. Also, the test solution is stable at around 60-70 ℃ for reaction, the clear solution is obtained, which sample completely dissolved. Comparing the results of the samples which reaction in same quality and different temperatures, as shown in Fig. 1.

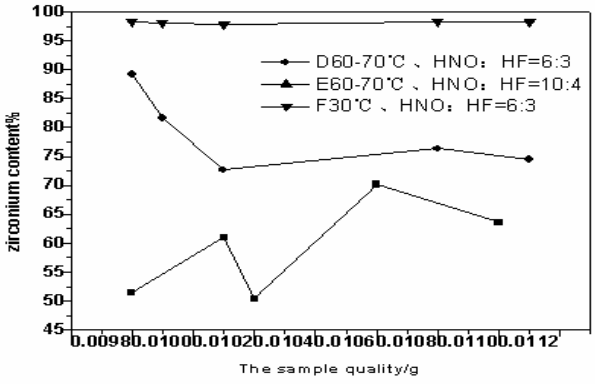

Fig. 1. The contrastive chart of the influence of temperature on the content

From Fig. 1, We can see that the influence of thermal control on dissolution results and product content is very big in the process of dissolution, especially before joining hydrofluoric acid, the influence of thermal control of nitric acid on dissolution process and test results.

The influence of acid on test results

The chemical nature of zirconium is not active and not reacts with hydrochloric acid, while sulfuric acid can heighten the activity of partial active zirconium in zirconium powder, then produce a lot of heat and dissolve active zirconium, but cannot dissolve other substances in zirconium powder completely. Partial active zirconium will dissolve in nitric acid by adding nitric acid, and produce less heat that not enough to dissolve the zirconium powder completely, most of samples are still stable. So choose hydrofluoric acid as the initiator when dissolving samples, on the basis of dissolving use nitric acid, enhancing the activity of zirconium powder and make sure the reaction can proceed smoothly and the samples can be completely dissolved. For different acid ratios, contents of zirconium powders were compared, and the results are shown in Fig. 2.

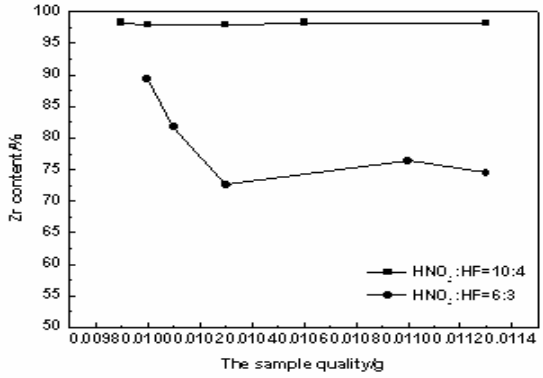

Fig. 2. The contrastive figure of zirconium content in the detective zirconium powder under different acids

From Fig. 2, We can see that the influence of the nitric acid proportion and hydrofluoric acid on the content of zirconium powder is also very big.

The influence of deionized water on test results

The reaction will be intense when add hydrofluoric acid, while in the initial stage of reaction, reactive speed is over fast that can lead to some powders which deposited on the bottom of the beaker are too late to participate in the reaction, the subsequent activity is not enough to make the reaction thoroughly. It can control the reaction rate firstly by adding deionized water, and also can float the samples which have settled at the bottom of the beaker , try to speed up the fluidity of samples inside test solution, let all samples can be dissolved in hydrofluoric acid and react completely.

Conclusions

The method by using ICP-AES is simple and more intuitive, accurate, and the operation is simple, the data is more intuitive, also shortens the time of testing and further ensure the accuracy of analysis results than the traditional method of testing zirconium content through impure content.

Keywords: Barkhausen noise, magnetic domain, residual stress, Root Mean Square, Power Spectrum.

Abstract: Magnetic Barkhausen noise(MBN) is a new technique on non-destructive testing of residual stress. The testing system based on virtual instrument was explored. It can achieve the MBN and deal with it in time. The technique is applied to analyze residual stress in the welding line of iron materials back and forth the heat treatment. Through comparing with the data of blind-hole method, the corresponding change between Barkhausen signals and residual stress is verified.

Introduction

At present, the methods which detect the residual stress of welding components are commonly used x-ray, strain gage method and acoustic emission. Moreover, magnetic Barkhausen noise on measurement of residual stresses in the nondestructive testing is a new technology. In 1919, the German physicist Barkhausen the first time discovered the Barkhausen effect. He observed ferromagnetic hysteresis loop of materials and found: curve is not smooth, see changes which jitter level amplified, known as the Barkhausen transition. This is the magnetization in the ferromagnetic material in the process of rapid changes of the local emergencies when using this detection coil to feel continuous changes. Which use headphones and listening, you can hear a noise form, it's known as the Barkhausen Noise(BN). MBN on the main signal analysis was used to determine the residual stress in ferromagnetic materials. Its advantage is to conduct nondestructive stress analysis, can be fully automated, can be a permanent record.

Labview software platform based on virtual instrument technology in recent years is an emerging discipline, mainly for building a computer analysis of test systems and automatic control system. Its softwares replace the traditional electronic devices, and give full play to a new generation of computer potential of big capacity and high-speed. It is an important signal acquisition and analysis tools. Virtual instrument technology is the use of high-performance modular hardware with highly efficient and flexible software to complete all kinds of test, measurement and automation applications. By MBN Virtual instrument technology for measurement of residual stress, realized the acquisition and real-time processing of the Barkhausen noise, and applied to residual stress analysis after heat treatment in the ferromagnetic material weld. The entire measurement process is a high degree of automation, high speed, high accuracy.

MBN Measurement Mechanism

During magnetization in the ferromagnetic materials, magnetic domain wall will happen mobile magnetic moment and the overall rotation within magnetic domains, which is a re-orientation of magnetic domain changes. A number of factors of the material structure that would impede and restrict magnetic domain wall motion and happen changes in the block, and in the irreversible magnetization of the back line hysteresis due to magnetic domain wall displacement and irreversible direction from a stable mutation to another stable direction, therefore, the magnetization in the region is composed of many irregular discontinuous jump, which will in the specimen surface of the receiving coils produce a series of chaotic electrical pulse signal, that is MBN signal [1], see Fig.1.

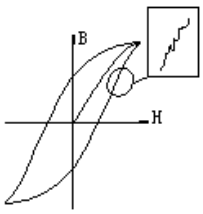

Fig. 1 Barkhausen noise

The size, direction distribution, jump on the instant process and the mutual relations of magnetization upspring, and the mechanical stress state of detected materials are closely linked[2]. Through processing and amplifying for observed MBN noise by the use of electronic methods, which usually displayed as noise pulse of amplitude, width and time interval without the rules. Combined with the virtual instrument technology, MBN noise is changed into residual stress values.

Testing Techniques and Instruments

The instruments required to detect Barkhausen signals are shown in Fig.2. To produce Barkhausen noise, a magnetizing field is generated and applied to a ferromagnetic material through an electromagnet[3,4]. The material reacts to the magnetic field and emits Barkhausen bursts, which are captured by a sensor consisting of a coil of conducting wire. The signal is then amplified and filtered. The amplitude is calculated by an RMS equation and Power Spectrum analysis and the data is digitized for display and output to a computer.

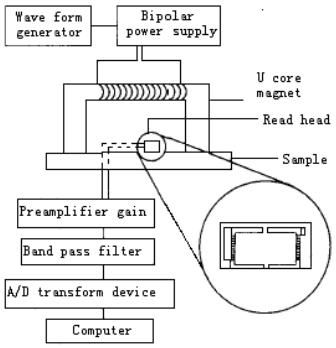

Fig.2 Testing instruments of MBN

The composition of the entire hardware system is divided into four parts: ① Excitation: input sensor excitation source of 20 Hz , 4V after the power amplifier by PCI1712 data acquisition cards. ② Sensors: compose a magnetic circuit with testing board, and then collect MBN signal by the receiver coil. ③ Receivers: integrated operational amplifier CA3140 is composed of preamp, qualcomm, analog low-pass filtering and postmagnification. MBN signals pass through PCI1712 data acquisition card into the PC. ④ PC: signal processing and display [5].

Software development is the core of virtual instrument. Labview provides a powerful data collection, processing and analysis functions. Graphical combination of functional modules achieves various functions required [6,7]. Through channel signal acquisition module, and then a noise signal analysis and processing, mainly through the processing RMS of time domain and Power Spectrum analysis of frequency domain, shows the micro-structural changes of the plate weld before and after heat treatment and MBN's changes caused by the residual stress changes.

Testing material

Testing material is plate, and its type is SM570. Size of the sample is 700mm×299mm ×45mm. Two plates have been used during the testing. Each has two states of heat treatment after welding or no.

Testing data of blind-hole method

Testing data of residual stress of the weld in blind-hole method is shown in tab.1.

Table 1 The most value of principal residual stress (σ_{max})(mpa) in blind-hole method

Testing place	No heat treatment after welding	Heat treatment after welding
1	168	118
2	180	84
3	173	40
4	236	96
5	167	94
Average	185	87

Results indicate the most average value of principal residual stress (σ_{max}) is 185MPa when the plate has not been treated by heating after welding. Whereas the average value is 87MPa when the plate has been treated by heating after welding. The fall ratio of residual stress is 53%. It shows residual stress of the weld has been released in a certain degree. The right effect of principal residual stress before and after heat treatment is show in Fig.3.

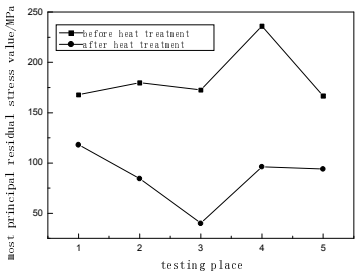

Fig.3 The distribution of principal residual stress

Testing data of magnetic Barkhausen noise method

Magnetic Barkhausen noise (MBN) is rather complicated. It was measured by self-made instrument. Data processing means, such as RMS equation and Power Spectrum analysis, was adopted to process the results of measurement [8].

Data analysis of RMS equation

The statistic analysis was done after sampling signal in a certain period. Eq. (1) of RMS follows:

$$\psi_x = \sqrt{\frac{1}{n}\sum_{i=0}^{n-1} x_i^2} \tag{1}$$

Sampling signal and RMS value of a certain signal is shown in Fig.4.

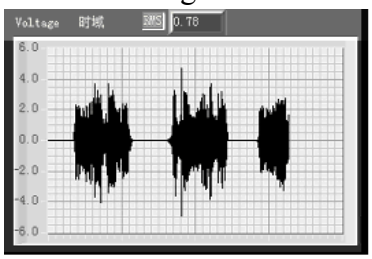

Fig.4 MBN sampling signal and its *RMS* value

Tab.2 shows testing data of RMS equation before and after the heat treatment. It is the average value of four measuring data in every testing place. We can find the signals' intensity before and after the heat treatment in X and Y direction has the dropping trend in whole, though some is increased. The dropping ratio is 26% in X direction and 17% in Y direction. It indicates that the intensity of MBN signal comes to drop with the release of residual stress.

Table 2 Testing data of rms (v)

Testing place	Before the heat treatment		After the heat treatment	
	X	Y	X	Y
1	0.728	1. 064	0. 596	0. 952
2	1.080	1. 190	0. 594	0. 708
3	0.766	0. 948	0. 482	0. 790
4	0.898	0. 746	0. 912	0. 836
Average	0.868	0. 987	0. 646	0. 822

Testing Data of Power Spectrum Analysis

On the basis of programming by Labview software, the MBN signal is transformed from time field to frequency field. Furthermore, it is analyzed by Power Spectrum to explain its change before and after the heat treatment. The distribution and analysis of Power Spectrum of a certain MBN signal is shown in Fig.5. It gives its maximum and corresponding frequency [9].

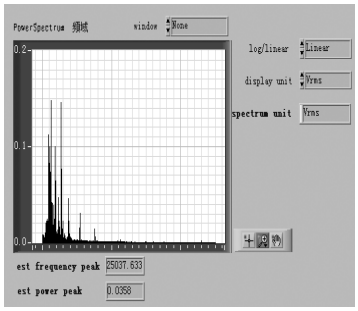

Fig.5 The distribution and analysis of Power Spectrum

Tab.3 is the testing data of Power Spectrum analysis in four testing place. It shows the frequency is about 25 kHz when the maximum of MBN signal and keeps in accordance with the sampling process before and after the heat treatment. But the maximum of Power Spectrum has been changed obviously whether X direction or Y direction. The dropping ratio of the maximum reaches 48% in X direction and 26% in Y direction in whole.

Table 3 Testing data of *power spectrum* analysis

Testing place	X direction before the heat treatment		Y direction before the heat treatment		X direction after the heat treatment		Y direction after the heat treatment	
	Frequency (Hz)	Maximum (V)	Frequency (Hz)	Maximum (V)	Frequency (Hz)	Maximum (V)	Frequency (Hz)	Maximum (V)
1	25032	0．0279	25151	0．0318	25104	0．0199	25035	0．0163
2	25090	0．0403	25034	0．0363	25247	0．0112	25105	0．0324
3	25089	0．0295	25149	0．0243	25175	0．0168	25322	0．0153
4	25205	0．0264	25103	0．0323	25174	0．0166	25177	0．0229
Average	25104	0．0310	25109	0．0310	25175	0．0160	25159	0．0230

Conclusions

Testing system of MBN signal has been constructed，which is made up of self-made MBN sensor and signal process circuit and PCI1712 and Labview software. The system becomes the basis of developing new non-destructive testing technique.

Indicates that the intensity of MBN signal comes to drop with the release of residual stress. We can find the MBN's intensity before and after the heat treatment in X and Y direction has the dropping trend in whole whether RMS or Power Spectrum analysis.

This technique can illuminate qualitatively the effect of the heat treatment on releasing residual stress, but it cannot analyze their relations quantitatively.

Keywords: PVC geomembrane; uniaxial tension test; mechanical response; stress-strain relationship

Abstract: The mechanical property of polyvinyl chloride (PVC) geomembrane was usually expressed using engineering stress-strain response in traditional uniaxial tension test. By failing to account for deformation of specimen during the test, the deviation of true stress and strain maybe caused from the test results. In this paper, the true stress-strain response of PVC geomembrane was investigated using uniaxial tension test. The photographic analysis method was used to measure axial and lateral true strain of specimen. The Poisson's ratio and true stress were also acquired based on measured true strain in the test. Then the true stress-strain relationship was obtained from the test results. By comparing with the engineering stress-strain results expressed by traditional method, it can be found that the engineering stress-strain result is unreasonable. The engineering stress-strain expression easily leads to the underestimation of the true stress.

Introduction

Evaluation of mechanical response of geomembrane by laboratory testing is very important for engineering structures involving geomembrane. Especially the stress-strain relationship is the key theoretical basis and foundation for engineering design and safety assessment[1]. But the traditional method of expressing the strain and stress does not consider the deformation of specimen during tension test[2][3]. That may lead to mistakes of test results. In current paper, the uniaxial tension test was performed to evaluate the stress-strain response of PVC geomembrane. The two method of expressing the stress-strain response of PVC geomembrane were examined and compared. The photographic analysis method was used to measure the axial and lateral true strain of specimen. And then, the true stress-strain relationship was obtained based on measured true strain during in the test. The differences between true stress-strain and engineering stress-strain responses were compared and analyzed in this paper.

Uniaxial Tension Test

Test Apparatus

The uniaxial tension test was conducted using the Multi-functional mechanical test system in geosynthetic laboratory of Research Institute of Hydraulic structures, Hohai University. The apparatus was controlled by electro-servo system. The tension force and displacement were automatically collected by sensors and computer. The test was conducted using strain-controlling mode. A strain rate of 1%/minute was desired and the crosshead speed for the test was 1.25 mm/minutes as required in ASTM D 4885-06[4]. The laboratory air was maintained at relative humidity of 50 to 70 % and a temperature of 25±2℃.

Test Specimens

In this paper, the uniaxial tension mechanical response of a 0.75 mm polyvinyl chloride PVC geomembrane was investigated. According to the results presented by Merry and Bray (1996)[5], there is no systematic variation in the stress-strain response of PVC geomembranes due to specimen width to length aspect ratio variations over a range of 0.1 to 5.5. So the specimens of PVC geomembrane with length of 200mm and width of 100mm were used in the experiments.

Measurement of Tension Force and Strain

The axial tension force of specimen was measured by a tension transducer which connected to the end of clamps. The minimum resolution and maximum capacity of transducer are 0.01kN and 10kN, respectively. The axial displacement of clamp was measured by Linear Variable Differential Transformer (LVDT) with minimum resolution and maximum capacity of 0.01mm and 800mm, respectively. The tension force and displacement were all automatically gathered by the acquiring system. And tension force-displacement curve can be shown on the software interface in time.

In order to acquire the true strain of the specimen, the CCD camera was employed to tracking the deformation of marking points on the surface of specimen. Then the true axial and lateral strains of specimen were all calculated by photographic analysis method[6]. To aid with the photographic analyses, a reference line was placed on the clamps, and a reference grid was drawn on the surface of specimens. The reference grid on the surface of specimen (10mm×10mm)was centered vertically and horizontally. Prior to the load application, both the grid lines on the specimen and the vertical edges of the specimen formed straight lines.

Expression of Stress and Strain

Axial Strain

Axial Engineering Strain

According to ASTM[3][4] and Specification for test and measurement of geosynthetics (SL 235-2012) [2], the axial strain of geomembrane specimen of uniaxial test is typically formulated as an axial engineering strain, ε_{aE}, as follows:

$$\varepsilon_{aE} = \frac{\Delta L}{L_0} = \frac{L_f - L_0}{L_0} \tag{1}$$

where L_0 is the original length of PVC geomembrane specimen between the clamps, ΔL is the specimen elongation, L_f is the separation between the clamps.

Engineering strains are usually used due to its simplicity and for the sake of consistency with normal design practice. The engineering strain definition is most appropriate at small strains. When larger strains are of interest, there maybe significant difference between the engineering strain and the true strain of specimen.

Axial and Lateral True Strain

The axial true stain ε_{aT} and lateral true strain ε_{lT} can be measured using photographic analysis method. Through analyzing the deformation of the marking points in the central of the specimen, axial and lateral true strains were obtained at any time during tests.

Poisson's Ratio

As presented by Giroud (2004) [7], the Poisson's ratio can be theoretically deduced. The relative volume change of PVC specimen throughout the test can be expressed as:

$$\frac{V}{V_0} = (1+\varepsilon_{aT})(1+\varepsilon_{lT})(1+\varepsilon_{tT}) \tag{2}$$

where V is volume of the specimen that corresponds to strain ε_{aT}, V_0 is the original volume of specimen at the beginning of test, ε_{tT} is true stain in thickness direction.

And the true stain in thickness direction can be calculated by:

$$\varepsilon_{tT} = -\nu\varepsilon_{aT} \tag{3}$$

where ν is Poisson's ratio.

For incompressible material, the relative volume change is equivalent to 0. As a result, Eq. (2) and Eq. (3) become:

$$(1+\varepsilon_{aT})(1-\nu\varepsilon_{aT})^2 = 1 \tag{4}$$

So the Poisson's ratio derived from Eq. (4) can be expressed as:

$$\nu = \frac{1}{\varepsilon_{aT}}\left(1-\frac{1}{\sqrt{1+\varepsilon_{aT}}}\right) \tag{5}$$

Cross Section Area

The cross section area on the centre of specimen corresponds to strain ε_{aT} can be expressed as:

$$A_\varepsilon = W_{\varepsilon=0}(1-\nu\varepsilon_{aT})\cdot T_{\varepsilon=0}(1-\nu\varepsilon_{aT})_\varepsilon = W_{\varepsilon=0}T_{\varepsilon=0}(1-\nu\varepsilon_{aT})^2 \tag{6}$$

where $W_{\varepsilon=0}$ is the original width of specimen, $T_{\varepsilon=0}$ is the original thickness of specimen.

Axial Stress

The axial engineering stress is defined on the assumption of constant cross section area of specimen. It can be calculated by dividing the observed tension force at each strain by the original cross sectional area:

$$\sigma_{aE} = \frac{F}{A} = \frac{F}{W_{\varepsilon=0}T_{\varepsilon=0}} \tag{7}$$

where σ_{aE} is the axial engineering stress, F is the measured axial tension force, A is the original cross section area of the specimen.

The axial true stress on the centre cross section of specimen corresponds to strain ε_{aT} can be calculated as:

$$\sigma_{aT} = \frac{F}{A_\varepsilon} = \frac{F}{W_{\varepsilon=0}T_{\varepsilon=0}(1-\nu\varepsilon_{aT})^2} \tag{8}$$

Results and Discussion

Axial True Strain

The comparison between axial true strain and engineering strain is presented in Fig. 1. The axial true strain was measured by photographic analysis method. The axial engineering strain was calculated by Eq. (1). It can be shown that the difference between axial true strain and axial engineering strain is not obvious when axial strain is less than 60%. The results show a good agreement with the data presented by previous studies performed by Wesseloo et al. (2004) [6]. For practical

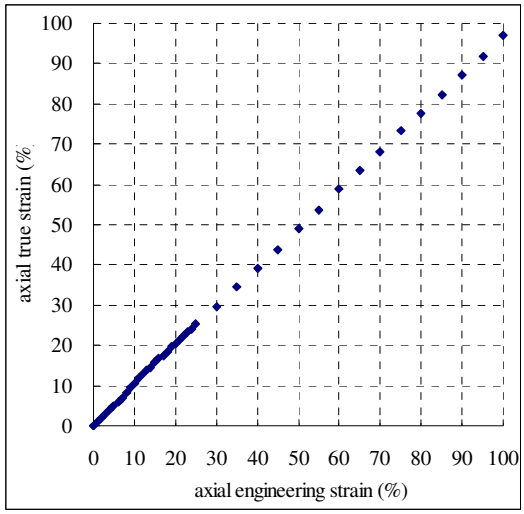

Fig. 1 Axial true strain-engineering strain relationship for PVC geomembrane

engineering application, difference between the two stains calculated by different methods can be ignored. When strain is greater than 60%, the axial true strain in the centre area of PVC geomembrane specimen is a little smaller than engineering axial strain. The test results reported by Merry and Bray (1996) [5]supported this conclusion.

Poisson's Ratio

The relationship between Poisson's ratio and axial engineering strain is presented in Fig. 2. The Poisson's ratio was calculated by Eq. (5) based on the measured axial true strain. The plots show that the Poisson's ratio of PVC geomembrane is not a constant and decrease with the increase of axial strain. So the Poisson's ratio is dependent on the strain state for PVC geomembrane.

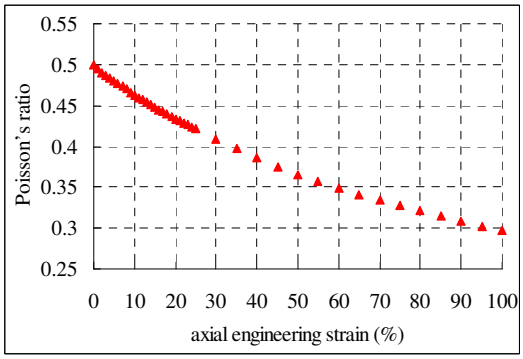

Fig. 2 Poisson's ratio - axial engineering strain relationship for PVC geomembrane

Cross Section Area

Fig. 2 shows the values of cross sectional area calculated by Eq. (6) based on the measured axial true strain, versus the axial engineering strain for the PVC specimen. It can be observed that the cross section area decrease with the increase of axial strain. So the traditional method of calculating engineering stress based on the constant cross section area for PVC geomembrane is not responsible.

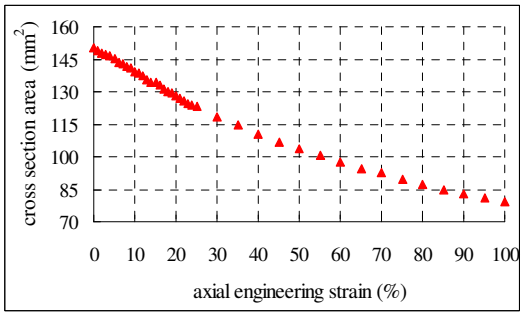

Fig. 3 Cross section area- axial engineering strain relationship for PVC geomembrane

True Stress-strain Relationship

The relationships between axial stresses and strains are shown in Fig.4. The engineering stress-strain and true stress-strain responses are compared in the same figure. The axial engineering strain and stress were calculated by Eq. (1) and Eq. (7), respectively. The axial true strain was directly measured using photographic analysis method. The axial true stress was calculated by Eq. (8) based on the measured axial true strain. As shown in Fig.4, both the engineering stress-strain and true stress-strain responses express approximate linear

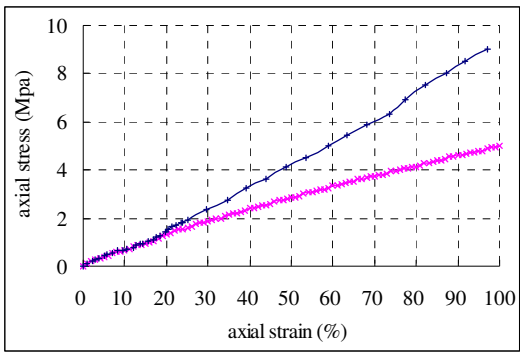

Fig. 4 Relationship of axial tension stress – strain for PVC geomembrane

relationship. An obvious difference can be observed between the engineering stress and true stress. For the same axial strain, the axial engineering stress is less than axial true stress. It is because that the axial engineering stress did not considering the decrease of the cross section area with the increase of axial strain. So the engineering stress-strain expression easily leads to the underestimation of the axial true stress of PVC geomembrane in uniaxial test. That may bring unsafe risk for engineering design.

Conclusions

In this study, the stress-strain response of PVC geomembrane was investigated with uniaxial tension test. The photographic analysis method was used to measure the true strain in axial and lateral direction of specimen during the test. The cross section area and true stress on the center of specimen were calculated based on the measured true strain. The following conclusions can be drawn from the test results:

(1) The difference between axial true strain and engineering strain of PVC geomembrane is not obvious when axial strain is less than 60%. For practical engineering application, the axial engineering strain can be used based on traditional uniaxial tension test method.

(2) Poisson's ratio of PVC geomembrane is not a constant. It is dependent on the strain state and decrease with the increase of axial strain.

(3) The cross section area of the centr of specimen decrease with the increase of axial strain. So the traditional method of calculating engineering stress based on the constant cross section area is not responsible.

(4) The stress-strain response of PVC geomembrane express approximate linear relationship. For the same axial strain, the axial engineering stress is less than axial true stress. So the engineering stress-strain expression easily leads to the underestimation of the axial true stress.

wkx@xznu.edu.cn

Keywords: Electromagnetic flowmeter; Partially-filled pipes flow measurement, Error correction.

Abstract. This paper designs the electromagnetic flowmeter in partially filled pipes (EMF-PF), which sensor alternate duties, sensing both the fluid velocity and fill height signals in order to get the flow in the partially filled pipes. Because the errors caused by two parameters measured, different sensitivities and zero-shifts reduce the accuracy of the EMF-PF, therefore calibration is needed. The repeated tests show that the third-order correction of the errors achieved good results.

Introduction

The flow measurement needs to measure flow velocity and fill cross-section to obtain the flow in partially filled pipes because the fill cross-section of fluid is changing[1]. The fill cross-section of fluid can be calculated by fill height in partially filled pipe. Based on this principle, the flow measurement of EMF-PF needs to measure both flow velocity and fill height. Thus the functional requirements of multi-parameter measurement are put forward for EMF-PF. At present, the fill height is obtained mostly by additional level sensor in EMF-PF, such as capacitive height gauge[2] and micromanometer[3]. However, there are the complex structure to EMF-PF using additional level gauge. This paper designs an EMF-PF sensor for measuring both flow velocity and fill height without additional level sensor. Because the errors caused by two parameters measured, different sensitivities and zero-shifts reduce the accuracy of the EMF-PF, therefore calibration is needed.

Principle

System architecture

The schematic diagram of the designed EMF-PF is shown in figure 1.

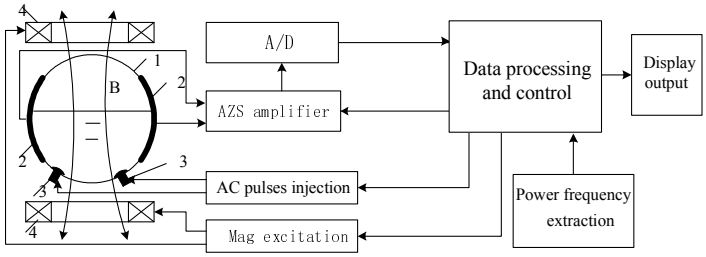

Figure 1 The schematic diagram of the EMF-PF architecture

In figure 1, 1 denotes the insulation pipes, 2 denotes the long-arc multi-electrodes, 3 denotes the signal injection electrodes, 4 denotes the coil.

One pair of long-arc electrodes is set on the pipe wall as the measurement electrodes. On the pipe bottom, one of pair of the electrodes is set as the signal injection electrodes that inject the AC pulses used to determine liquid fill height. Coils are used to produce the magnetic field necessary for flow measurement. The raw signals are transmitted via an interconnection cable to a converter, where the data are used to calculate the desired flow and height. The hardware composing of converter mainly includes the module of power frequency extraction, the magnetic field excitation module, the AC

pulse signal injection module, auto-zero signal amplification module, analog-digital conversion module, data processing module and display output module.

Measurement principle

A narrow pulses for measuring fill height is applied through the signal injection electrodes, and operates between the AC wide pulses to the coils. The measurement electrodes alternate duties, sensing both the flow and fill height signals. Both the flow and fill height raw signals are alternately disposed in different time period by the same signal processing channels in order to avoid the impact of electrical signal between them. System working timing is shown in figure2.

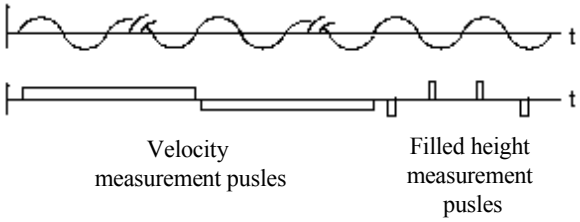

Figure 2 The EMF-PF flow measurement working timing

In the flow velocity measurement cycle, the AC wide pulses inject to the coils, and the AC narrow pulses to determine fill height are turned off. The measurement electrodes sense flow velocity signal.

In the fill height measurement cycle, the AC narrow pulses inject to the electrodes that set at the pipe bottom, and the AC wide pulses to the coils are turned off. The measurement electrodes sense fill height signal.

When the AC pulses inject to the electrodes that set at the pipe bottom, A stable electric field is formed within the liquid in partially filled pipes.Based on Ohm's law, the current density vector $\vec{j}$ is

$$\vec{j} = \sigma \vec{E} \tag{1}$$

where σ is the liquid conductivity, the electric field vector $\vec{E}$ is

$$\vec{E} = -\nabla \psi \tag{2}$$

If the conductivity of the liquid is homogeneous, isotropic, the electric field distribution within the liquid is associated with the distance from the electrodes to which the AC pulses inject[4]. Hence, the fill height signal Vo that is sensed by the measurement electrodes has a single-valued correspondence with the fill height H. The relation between H and Vo may be expressed as follow:

$$H = k f\left(\frac{V_i}{V_O}\right) \tag{3}$$

Where, k is a coefficient that can be calibrated by experiment, and Vi is input voltage value. We can use the equation (3) to calculate the desired fill height.

According to the measurement electrodes sensing flow velocity and fill height data, the volume flow Q in partially filled pipe can be obtained[5]:

$$Q = \frac{D^2}{4}[Arc\cos(1-2\alpha) - (1-2\alpha)\sqrt{1-(1-2\alpha)^2}]v \tag{4}$$

where, v is flow velocity, and α is flow fill degree, and $\alpha = \frac{H}{D}$. D is pipe diameter, and H is fill height.

Error correction

When the EFM-PF is employed to measure the flow in the partially pipes, both of the flow velocity and the fill cross-section needs to be measured. Because the errors caused by two parameters measured, different sensitivities and zero-shifts reduce the accuracy of the EMF-PF, therefore calibration is needed. The repeated tests show that the third-order correction of the errors achieved good results.

Established error correction curve of third-order parameter matrix equation is as follow:

$$E(\lambda)=\begin{bmatrix}\lambda^3 & \lambda^2 & \lambda^1 & 1\end{bmatrix}\begin{bmatrix}a\\b\\c\\d\end{bmatrix} \quad (5)$$

Where, *a, b, c, d* is constant matrix.

$a=\begin{bmatrix}a_x\\a_y\end{bmatrix}$, $b=\begin{bmatrix}b_x\\b_y\end{bmatrix}$, $c=\begin{bmatrix}c_x\\c_y\end{bmatrix}$, $d=\begin{bmatrix}d_x\\d_y\end{bmatrix}$

$E(\lambda)=\begin{bmatrix}x(\lambda)\\y(\lambda)\end{bmatrix}$, λ is intermediate parameter, $0\le\lambda\le 1$

On the equation (2) for first order derivative, we obtain

$$E'(\lambda)=\begin{bmatrix}3\lambda^2 & 2\lambda^1 & 1 & 0\end{bmatrix}\begin{bmatrix}a\\b\\c\\d\end{bmatrix} \quad (6)$$

For collected sample of n point $P_i(i=1,\cdots,n)$, it need to express in n cubic curve segment. The cubic sample curve is shown in figure 3.

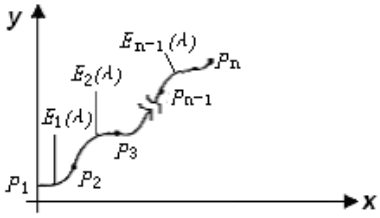

Figure 3 The cubic sample curve

In figure 3, the boundary condition of each cubic curve segment is

$E_i(0)=P_i$, $E_i(1)=P_{i+1}$

$E_i'(0)=P_i'=kP_i$, $E_i'(1)=P_{i+1}'=kP_{i+1}$

Where, *k* is constant matrix. λ =0,1 are respectively substituted in equation (2) and equation (3), we obtain

$$\begin{bmatrix}P_i\\P_{i+1}\\P_i'\\P_{i+1}'\end{bmatrix}=\begin{bmatrix}0&0&0&1\\1&1&1&1\\0&0&1&0\\3&2&1&0\end{bmatrix}\begin{bmatrix}a\\b\\c\\d\end{bmatrix} \quad (7)$$

The inverse matrix of matrix 7 is

$$\begin{bmatrix}a\\b\\c\\d\end{bmatrix}=\begin{bmatrix}2&-2&1&1\\-3&-3&-2&-2\\0&0&1&0\\1&0&0&0\end{bmatrix}\begin{bmatrix}P_i\\P_{i+1}\\P_i'\\P_{i+1}'\end{bmatrix} \quad (8)$$

By equation (8), the value of *a, b, c, d* can be obtained. Hence, error correction equation *E*(λ) can be obtained by sample point $P_i(x_i,y_i)(i=1,\cdots n)$.

According to given error limit, the system continuously implements error correction to *E*(λ). The software algorithm steps is as follow:

I. Collected data of sample point (x_i,y_i) is entered.

II. Compared (x_i,y_i) with $(x_i,E(x_i))$, if $|y_i-E(x_i)|<\varepsilon$, then go to 5, ε is error limit.

III. Point (x_i,y_i) is used to replace next sample point (x_k,y_k)

IV. Determining whether (x_k, y_k) is the first point, if it is then re-fit $E_1(x)$ .if it is not then re-fit $E_{n-1}(x)$

V. If continuing to correct, then go to 1. If not, then over.

The algorithm is embedded into the flow measure -ment program to achieve measurement error dynamic correction and compensation

Experiments

The schematic diagram of the EMF-PF experiment system is shown in figure 6.

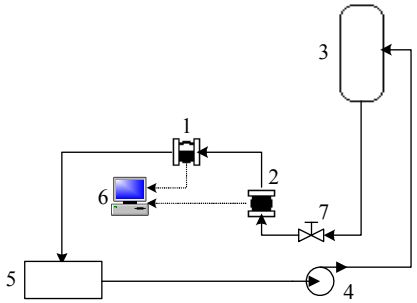

Figure 4 The experiment system of the EMF-PF

In figure 4, 1 denotes the EMF-PF, 2 denotes the standard EMF, 3 denotes stable pressure watertower, 4 denotes the pump, 6 denotes upper PC, and 7 denotes water valve.

The experiment prototype of EMF-PF is installed in horizontal straight pipe. ADMACSE standard flowmeter is installed in vertical pipe. The experiment results of EMF-PF prototype is shown in figure 5.

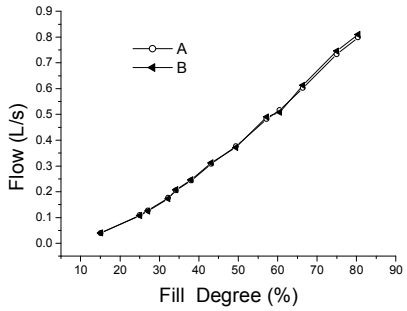

Figure 5 The EMF-PF experimental results

The experiment results show the flow measurement relative error of EMF-PF prototype is less than 2% except flow measurement below 15.1%fill degree.

Summary

This paper designs an EMF-PF for the flow measurement of partially filled pipe without additional level sensor. Experiment result shows that the measurement accuracy of this EMF-PF meets the actual requirements by software correction.

Keywords: Turbiscan, emulsion stabilization ,sedimentation behavior

Abstract: Turbiscan is a new rapid and non-destructive method that has found increasing use in detecting physical destabilisation of concentrated and liquid dispersions. This review introduces the history and development of Tubiscan and focuses on applications of Turbiscan. The applications of Tubican were wildly used in dispersion stability of drug, carbon nanotubes dispersion, alumina suspension, emulsion stabilization and sedimentation behavior studying.

Introduction

Colloids and dispersions are inherently unstable systems which can be considered as kinetically stable if the destabilization rate is enough small compared with the expected lifespan[1]. The analysis of the dispersion instability is prime importance. The currrent techniques used to detect physical destabilisation are either simply the naked eye or optical analytical methods, such as microscopy, particle size and zeta potential. The accuracy and scope of these methods are reduced by sample dilution, due to most colloidal systems and dispersions are quite concentrated and opaque.

In this review, we describe a relatively new non-destructive method (no sample dilution) that was developed for detecting physical destabilisation of concentrated and liquid dispersions (emulsions, suspensions, foams, etc.). The method is based on measurement of particle migration (creaming or sedimentation) and particle-size variation (coalescence)[2]; it was called TURBISCAN.

TURBISCAN History and Development

The history and development of the TURBISCAN technique dates back to the invention of the Le TURBISCAN by G. Meunier in the early 1990's[3]. Then the TURBISCAN MA 1000 and TURBISCAN MA 2000 were developed[14]. A pulsed near infrared (λ = 850 nm) was used as light source and the sample concentrated could reach 50%. The next development of TURBISCAN was TURBISCAN LAB which using the pulsed near infrared (λ=880 nm) as light source. The TURBISCAN LAB could change the temperature of sample and detect high concentrated sample(up to 95%).

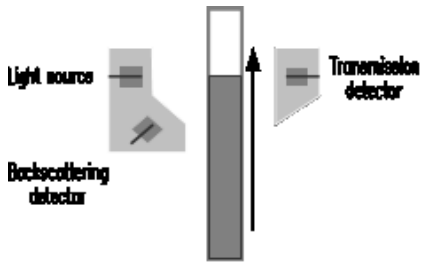

Fig.1

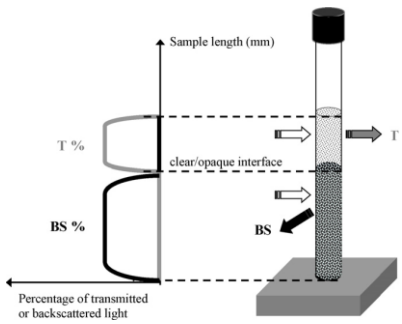

Fig.2

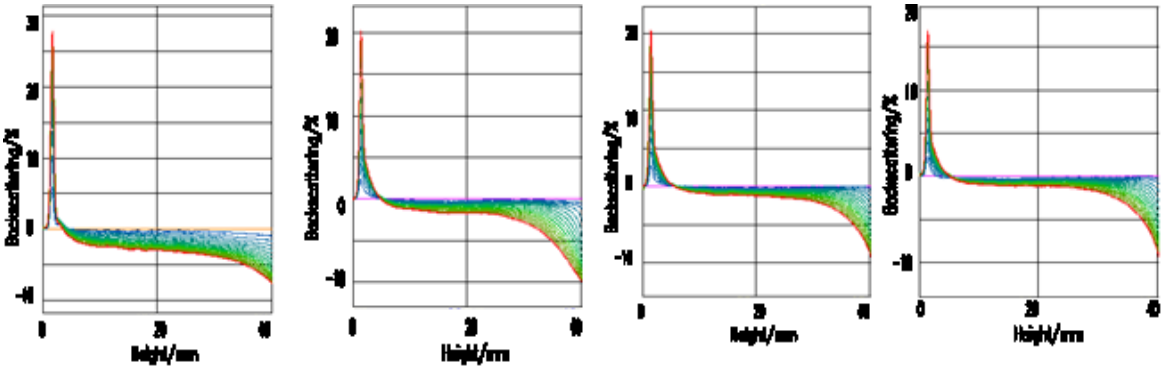
Measurement principle.



The TURBISCAN head is composed of a pulsed near infrared light source (λ = 850/880nm) and two synchronous detectors: a transmission detector which receives the light going across the sample (at 0° from the incident beam) and a back scattering detector which receives the light scattered

backward by the sample (at 135° from the incident beam(Fig.1). The detection head scanned the entire length of the sample acquiring transmission (T) and backscattering (BS) data(Fig.2)[5].

TURBISCAN Applications

The dispersion stability of Drug.

We firstly use TURBISCAN LAB to study the stability of pesticide WDG[6]. The sedimentation thickness of WDG suspension decrease as the contents of polymer dispersant increased(Fig.3). The particle diameter of WDG reach minimum as the Mw=12000. The results show that the stability of WDG suspension related with content and molecular weight of dispersant[3]. The effect of surfactant, polymer and dilution on dispersion stability of aqueous suspensions of drug particles was ivestgated by mesuring the sedimentation rate of drug particles by using Turbiscan MA2000[6,7]. he results suggest that a combination of surfactant and polymer provides more stable aqueous dispersion of drug particles than surfactant alone or polymer alone. The drug particles gradually sediment before dilution, while after the dilution they sediment a slightly faster.

(a) (b) (c) (d)

Fig.3 Backscattering profile of WDG suspension system containing different content of dispersant

Carbon nanotubes(CNTs) dispresion.

The dispresion of CNTs in solvents by either modifying the CNT surface chemistry or by the addition of surfactants has attracted an enormous amount of attention of reachers. Hyoung-Joon Jin et al have studied the stability of the multiwalled carbon nanotubes(MWCNTs) dispersions with various surfactants by using Turbiscan Lab. By comparing the delta transmittances and average transmission rates of the MWCNTs dispersions,they found the aqueous MWCNT dispersions with surfactants were more stable than that without surfactants[8]. In the other hand, the alkylated MWCNTs could disperse in common organic solvents without the use of surfactants[9]. The dispersion stability poly(4-vinylpyridine)-encapsulatedMWNTs is better in alcoholic medium than other solvents due to the chemical affinity of P4VP with alcohol[10].

Alumina suspension.

Małgorzata Wiśniewska et al studied the temperature effect on the stabilization – destabilization propertiesof the alumina (Al2O3) – polyacrylic acid (PAA) systems.The data obtained by the use of Turbiscan LabExpert and the calculated values of Turbiscan Stability Indexes (TSI) indicate that the addition of PAA causes lowering of the alumina suspension stability towards settling at both 15 and 35 °C. On the other hand, at 25 °C the polymer adsorption improves insignificantly the stability of Al2O3 suspension[11].They also investigated the influence of solution pH on the adsorption mechanism of polyacrylamide (PAM) on the alumina surface and stability of its suspension in the presence of polymer. The results indicate that the stability of suspensions depends on the molecular weight of the polymer and the pH of the solution. The suspension of alumina in the absence of polymer at pH 9 has much lower stability compared to the systems at pH 3 and pH 6 (electrostatic stabilization). The addition of polymer to the alumina suspension results in a drastic reduction of its stability at pH6 (close to pHIEP of PAM, bridging flocculation) and slight deterioration in the pH values 3 and 9[12]. The influence of solution pH and polymer molecular weight on the stability of

mixed alumina-silica oxide suspension in the absence and presence of polyacrylic acid (PAA) was shown in Tab.1[13]. The composition of the adsorbent was: Al2O3 (96%) and SiO2 (3%). To obtain changes in the stability of the investigated systems as a function of time the turbidimetry method was applied. It was shown that the suspension without the polymer was characterized by the smallest stability at pH 9, whereas at pH 3 and 6 the systems are successively stable. PAA with the molecular weighs 2000 at pH 3 (large deterioration of system stability conditions) and PAA (all molecular weights) at pH 9 (considerable improvement of suspension stability) have a great effect on the alumina-silica stability. The specific conformation of PAA chains on the solid surface which depends on solution pH and polymer molecular weight is responsible for the stabilization – flocculation properties of polyacrylic acid in the colloidal suspension.

Table 1 The TSI indexes for SA 96 suspension in the absence and presence of polyacrylic acid.

System	TSI		
	pH=3	pH=6	pH=9
SA 96	7.52	7.55	63.20
SA 96–PAA 2000	64.30	6.36	8.82
SA 96–PAA 100000	5.80	4.41	5.35
SA 96–PAA 240000	2.22	5.61	6.45

Suspension mechanism study.

Settling properties of barium sulphate suspensions have been examined by turbiscan measurement. The settling results show a sharp transition between the behaviour of aggregating and well-dispersed suspension. For the two polyelectrolyte dispersants used (PAA and PSS), at the transition the adsorbed amounts correspond to a samevalue of the electrokinetic potential, avalue that agrees well with DLVO theory predictions[14].

A better understanding of sedimentation behaviours of mineral suspensions has been investigated by three complementary optical methods of dispersed systems analysis: laser granulometry, electrophoresis measurements, and concentrated dispersion analyser. Only the study of sediment formation by Turbiscan MA 2000 has shown that before this limit of stabilisation, nascent agglomeration phenomena occurs although the suspension seems globally stabilised. In addition, by this approach, two destabilisation behaviours have been identified: one corresponding to the global migration of particles without sediment formation which corresponds to compression settling[15]. Physico-chemical stability of mineral suspensions , studied by optical dispersion analysis (Turbiscan MA 2000) enables the clarification rate to be measured and to propose a new global parameter, the "phase separation index"[16]. In J. Bongono's work,[17] the multiple light-scattering model through the optical analyzer, Turbiscan MA 2000 is used to determine the mean settling velocities of monodisperse glass beads and two polydisperse samples of powders, kaolin D and alumina, differing by their particle size distribution, their shape and their surface properties.

Emulsion stabilization.

Caroline Lemarchand et al. [18] prepared oil-in-water nanoemulsions by using graft copolymers with dextran(DEX) and poly-ε-caprolactone(PCL) and studied the emulsion stabilizing abilities by using the Turbiscan. They found that PCL-DEX copolymers successfully stabilized ethyl acetate-in-water emulsions, even in the absence of additional surfactants. This stabilizing ability of PCL-DEX related to the localization of their blocks with regard to the oil–water interface .The optical characterization of the stability by means of the Turbiscan gives interesting information about the global stability of the emulsions. I. Roland et al [19]used Turbiscan to characterize oil-in-water emulsions with difference surfactant concentration. All the emulsions exhibit a tendency to creaming. The creaming kinetics calculated from the backscattering differential profiles obtained. L. Day et al [20] found that fish oil emulsions, stabilized using sodium caseinate (25% w/w oil and 0.1–1.0% w/w sodium caseinate giving oil-to-protein ratios of 250–25), were either homogeneous or exhibited depletion or bridging flocculation, depending on the concentration of protein in the formulation.

Summary

In this paper we have presented an overview of the history, theory, and practice of the Turbiscan technique, with emphasis on the fundamentals principles underlying the technique and practical examples. As Turbiscan is a relatively new technique, it is likely to become more widely used in the years to come. We hope that this paper facilitates such further development

Keywords:SEC-MALLS, molecular weight, molecular weight distribution, macromolecular polymer

Abstract: This paper reveals the development and significance of size exclusion chromatograph/multi-angle laser light scattering(SEC-MALLS) for determination of the molecular weight and characterization of the molecular weight distribution. This technique has been applied in many aspects, such as biology, polymer and carboxylate surfactant. It has made a big contribution to study the property of macromolecular substances.

Introduction

There are something, which are very crucial for product properties, such as molecular weight, molecular weight distributions, size and branching of polymer. These directly influence many polymer physical properties, such as, tensile strength, chemical resistance viscosity and solubility [1], especially the molecular weight, which can affect polymer physical properties. Therefore, the accurate determination of polymer molecular weight is essential to reveal the properties and activities of a kind of materials.

A lot of methods have been applied to determine polymer molecular weight, such as Vapor-pressure Osmometry, Gel-permeation Chromatograph and Light-scattering [2], but they have some drawbacks, respectively. Recent years, a new technique, SEC-MALLS has been used for determination of molecular weight and molecular weight distribution of polymers, especially for branched ones [3]. This allows the computation of the weight-average molecular weight (Mw). Various other molecular weight averages [number-average molecular weight (Mn) and z-average molecular weight (Mz)] are then computed from the distribution curve. Mw is the most accurate average that can be obtained by SEC-MALLS [4] .

Device and Principle

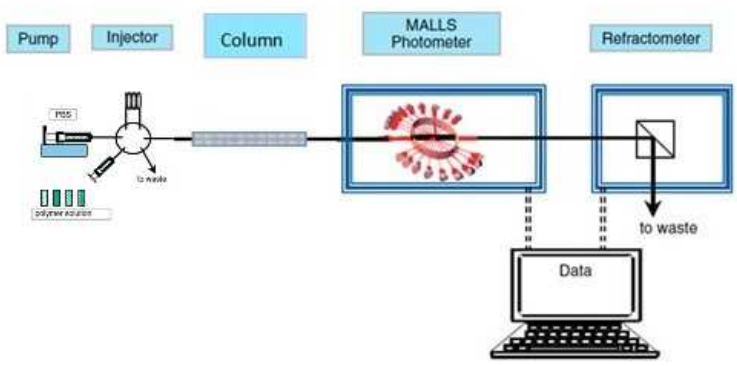

Fig. 1 Schematic of the SEC-MALLS system

The system consists of a syringe pump, an injector with a sample loop, a column, a MALLS photometer and a refractometer, as shown in Fig.1. The polymer samples are prepared at an accurate concentration and keep 24h for dissolution. The solution is filtered by using a 0.22 μm syringe filter. In each experiment, samples continuously flow through the system at a rate of about 0.5 mL • min–

1 by using a syringe pump. The known samples responses of the MALLS photometer and refractometer are used as baselines. An amount of 2 mL of each polymer solution is injected into the sample loop and infuse through the flow cells of MALLS and RI detectors. The MALLS and RI data are collected simultaneously by using a computer ASTRA software [5].

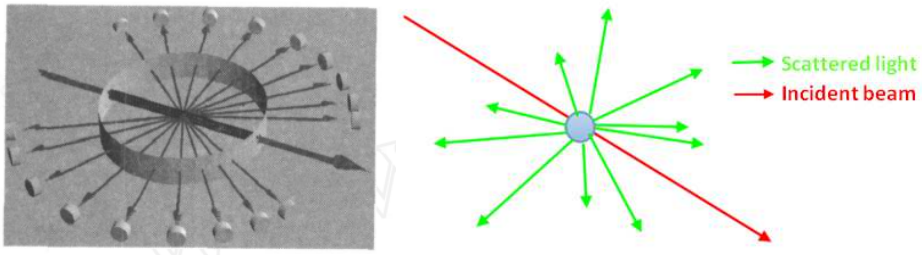

Fig. 2 Light scattering and collecting light

SEC-MALLS online determine the molecular weight and molecular weight distribution of polymers, which apply that light scattering intensity is in proportion to relative molecular mass and concentration, and light scattering intensity in different angles is relative to molecular size [6,7]. When light source shines a laser on to the polymers, incident beam will occur scattering, then scattered light will be collected and detected by 18 multi-angle laser light scattering, Fig. 2 shows that.

So the molecular weight for polymers can be calculated according to the following equations:

$$K^{*}C/R(\theta)=1/[MwP(\theta)]+2A_2C \quad (1)$$

Where: R(θ) is the excess Rayleigh ratio; P(θ) is the particle scattering factor; C is the concentration of the polymer particles (g/mol); Mw is the weight-average molecular weight; A2 is the second virial coefficient (ml • mol/g2); θ is scattering angle and K* is a constant.

For vertically polarized incident light with a wavelength $\lambda 0$ in vacuum, K* is given by:

$$K^{*}=4\pi^{2}n2\ 0/\lambda_0\ 4N_A(dn/dc)^2 \quad (2)$$

Where: n0 is the refractive index of the solvent at wavelength $\lambda 0$; NA is Avogadro's number and dn/dc is the specific refractive index increment of the polymer [3]. Using the obtained data make a plot of K*C/R(θ) vs. Sin2(θ/2), and the slope is the mean square radius, while Mw can be directly determined from the intercept at zero angle [8].

The application of SEC-MALLS

Biological

Light scattering is almost the few method for the determination of the molar mass and the structure of polymer [9]. Because of the limitation of this approach: polydispersity of the sample, nonideal thermodynamic behavior of many polymers, unknown conformation in solution of some molecules and possible interactions between the polymers studied. But these limitations can be overcome by SEC-MALLS.

TAB. 1 THE ACCURACY OF SEC-MALLS

Sample	declared values Mw	Measured value Mw	D	Relative deviation(%)
PS-1	5900	6050	1.005	2.54
PS-2	11800	11460	1.002	-2.88
PS-3	47300	47000	1.004	-0.634
PS-4	112000	112300	1.008	0.268
PS-5	212000	216900	1.006	2.31

In the aspect of biological, SEC-MALLS has been employed to characterize the mass-average molar mass, z-average radius of gyration and second virial coefficient of biological macromolecules [5]. Through the SEC-MALLS technique, the molecular weight or the structure of natural polysaccharide [8,10], hydroxyethyl starch [11], protein aggregates [9,12], hyaluronic acid [13], cationic hydroxyethyl cellulose derivatives [5] and the plasma substitute succinylated gelatin [14] has been obtained. For instance, Determination of Molecular Weight and Its Distribution of Hyaluronic Acid by Combination of Multi-angle Laser Light Scattering Instrument and Size Exclusion Chromatography [13]. It is known by principle of measurement that macromolecular compound Mw is its absolute molecular weight by this method, and its error is caused by the instrument detection. SEC-MALLS detect the Mw of Polysaccharide standards, then they compared measured value with the declared values, the conclusion showed that accuracy of the method was very well representated in Tab. 1.

This method was also used in food additives and drug formulations to determine the molar mass and molecular weight distribution. The retention time of drug in the body is very important and the drug’s structure depends on the molar mass and molecular weight distribution, so the determination the molecular weight and the characteristics of molecular weight distribution are meaningful to the study of biological macromolecules. The results of the usage of SEC-MALLS technique demonstrate that the method is simple, accurate, reproducible and high separation and can be applied to test the molecular weight, molecular weight distribution and structure of biological macromolecules [11,15].

Polymer

Molecular weight is a key, fundamental property of a polymer, thus the use of SEC-MALLS has been established as an effective method for the direct determination of molecular weigh [16]. This technique was used to characterize several fluoroalkyl acrylic, fluoroalkyl methacrylic polymers, perfluoropolyethers and hydrocarbon polymers. To yield accurate results, the concentration detector must be carefully calibrated and it is essential that the refractive index increment (dn/dc) be known for the polymer being analyzed-in the mobile phase employed. It is best if dn/dc is determined at the same wavelength employed by the light scattering detector and that it is relatively constant across the sample being characterized. They have successfully characterized fluoroalkyl acrylic samples with molecular weights (Mn) in excess of 1 000 000 g/mol. An overlay of elution chromatograms for an extended series of primary polystyrene standards ranging from 1100 g/mol to 1 600 000 g/mol is shown in Fig. 3.

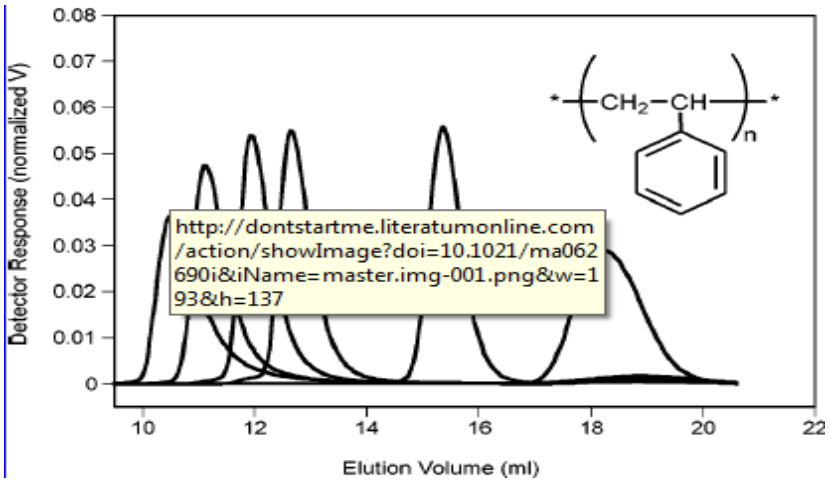

Fig. 3 GPC-MALS data for a representative series of pol

y(1,1,2,2-tetrahydroperfluorodecyl acrylate) macroinitiators made using ATRP

Finally, they concluded, SEC-MALS in α, α, α-trifluorotoluene mobile phase has been employed successfully to determine molecular weight and molecular weight distribution for highly fluorinated (hydrocarbon insoluble) fluoroalkyl acrylic polymers and hydrocarbon polymers. It is the mainstay technique for determination of molecular weight and molecular weight distribution of synthetic polymers [17].

The series of PAM [18] samples was characterized with SEC-MALLS and its data is correlated well with the previously reported literature values. At the same time, information about the radius of gyration and molecular structure was obtained. Furthermore, differences in polymer structure can be observed depending on the polymerization conditions [19].

Carboxylate surfactant

The MALLS method have begun to use since 1980s [20,21], coupled with revolution in computer and with development of SEC, which makes SEC-MALLS a perfect technique for determining polymer absolute molecular weight and molecular weight distribution. Raymond et al. [22] have reported their effort to develop and validate a SEC-MALLS method to directly determine absolute molecular weight and molecular weight distribution of HPMCAS(hypromellose acetate succinate). Due to the properties of HPMCAS, they use a mixed solvent to create a challenging condition for the SEC-MALLS method that uses refractive index detector. Finally, their results and the design of experiments indicate that the method is accurate and robust for determining HPMCAS absolute molecular weight and molecular weight distribution.

Recently, we are studying the SEC-MALLS method to directly determine absolute molecular weight and molecular weight distributions of carboxylate surfactant. The sample solution of carboxylate surfactant at 2 mg/ml were prepared by adding a weighed amount of polymer into a vial and dissolving it with a measured volume of mobile phase. Then the MALLS data were collected and processed by Wyatt ASTRA software. Representative chromatograms of the sample polymer are shown in Fig. 4. We use measured light scattering signals, refractive index signal, sample concentration and injection volume to calculate the dn/dc values in software to gain the molecular weight of Carboxylate surfactant. The statistics of these measurements are listed in Tab. 2.

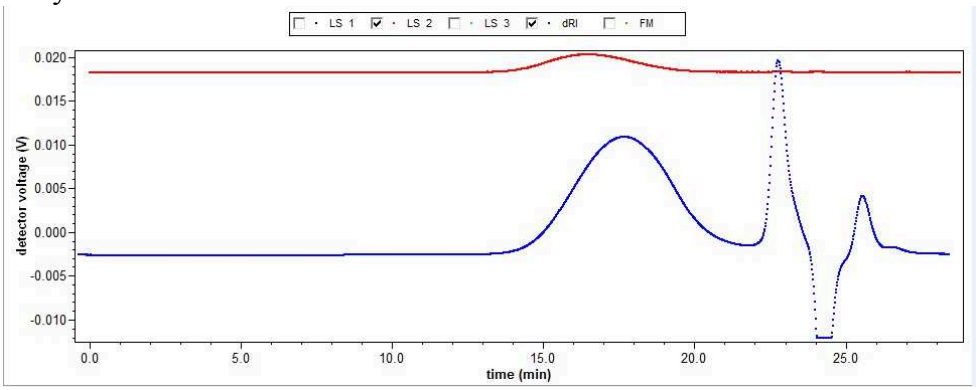

Fig. 4 Elution volume of sample

TAB. 2 STATISTICS OF THESE MEASUREMENTS

Sample	dn/dc	Mn	Mw	Mw/Mn
Sample-1	0.1591	8684	14490	1.622
Sample-2	0.1594	11050	15560	1.408
Sample-3	0.1594	8062	14490	1.797
Sample-4	0.1589	9874	14710	1.49
Sample-5	0.1591	8385	14390	1.716
Sample-6	0.1589	9672	15140	1.565

The above result and experiment prove that the method is accurate and robust for determining carboxylate surfactant absolute molecular weight distribution.

Summary

A simple, rapid, precise method was developed and validated for determination of molecular weight. As is concluded in this review, this approach is very significant to study the property of polymer and has a wide application. However, the reach method for polymer are needed to develop.

Application of Polycarboxylic Acid Anti-Crease Finishing Agent for Silk

Xulei[1,a]

[1]No. 287, Xuefu Road, Suzhou Institute of Trade & Commerce,Shi-hu International Education Park, Suzhou city, Jiangsu Privince, CHINA

[a]1981_xl@163.com

Keywords: polycarboxylic acid; silk; anti-crease finish

Abstract: Polycarboxylic acid anti-crease finishing agent is used to finish silk. The optimal finishing process was selected through orthogonal experiment. The optimal process conditions were as follows. The optimal concentration of both finishing agent Y and magnesium chloride was 100g/L. The optimal baking temperature and baking time were 160 ℃ and 3min, respectively. The results show that the silk fabrics treated by finishing agent Y had high strength retention and washing fastness. In addition, the effect of ant-crease finishing on the whiteness of fabrics was small.

Introduction

Silk fabric is characterized with gentle gloss, soft feeling, moisture absorption, ventilation, lightness and nature. The garment made from silk is not only artistic and comfortable but also possesses a multi-healthcare function.However the poor rebound resilience and easy-wrinkle have restraint the application of the garment. Therefore, it will bring new chance to the silk industry to improve the wrinkle resistance and the level of the silk fabric. 2D resin (DMDHEU, dihydroxy methyl two hydroxy ethylene urea) is one kind of traditional anti-crease finishing agents.Though it has received a confirmed wrinkle-resistance ability applied in natural fabrics and blended fabrics, there exists a problem of the release of formaldehyde on fabrics.[1] Four carboxylic acid (BTCA) is an excellent and special no formaldehyde anti-crease finishing agent for silk which can provide silk fabrics with good wrinkle-resistance ability, protect their original characteristics (such as whiteness, strength and drapability) and improve its dyeing property.[2] But the application of BTCA is limited for its high cost. So it is important to find an easy-using and eco-friendly anti-crease agent with a relative low price and high properties to meet the needs of customers and producers.

Experiment

Materials & Instruments

Material: silk habotai.

1)Drugs: anti crease finishing agent Y (citric acid and maleic acid molar ratio of 1:2 mixture), magnesium chloride (CP), JY08 (industrial grade), peregal O (industrial grade).

2)Instruments: HM-450 type pneumatic electric rolling vehicle, YG541B fabric crease recovery tester, DSBD-1 digital whiteness meter, YG026 fabric strength tester, SW-12A type washing fastness tester ， LA-250 type test for heat setting machine.

Experimental methods

Finishing process[3]

The silk was immersed in the bath ratio 1:30, temperature 30 ℃ finishing solution, two dipping and rolling, pick-up 90%. Then the silk at 90 ℃ drying 4min, baking in a condition, fully washed in hot water of 50 ℃, cold water washing, drying.

Test Method

1) Whiteness:

The samples were folded into four layers, the DSBD-1 tested on both sides of the instrument and taking the average value of whiteness.

2) The wet crease recovery angle (anelastic):

Sample was immersed in 0.2% peregal O solution, removed after soaking 5min, Silk is placed between two layers of filter paper and absorbed the water.According to (GB/T 3819-1997 Textile fabrics Determination of the recovery) in the vertical method.

3) Breaking strength

According to “GB/T 3923.1 - 1997 textile fabric tensile properties of first parts: the breaking strength and elongation at break were determined", Taking the average value in warp and weft fabrics after 3 times test. Silk breaking strength retention rate is calculated as:

Breaking strength retention (%) = (After finishing silk breaking strength/ Before finishing silk breaking strength) ×100％

4) Soaping fastness

According to “GB/T 3921-2008 textile color fastness resistance soaping fastness" Test.

Results and discussion

Finishing conditions selection

Select the finishing agent Y dosage, magnesium chloride dosage, baking time of 3 factors, Because the catalyst and anti-crease agent dosage ratio of 1:1 is better, so the test was used to maintain this ratio.Orthogonal test results as shown in table 1.

Table 1 Results of orthogonal test of anti-crease finishing

Serial number	Anti wrinkle agent dosage of Y (g/L)	Baking temperature （℃）	Baking time （min）	DWRA （°）	WWRA （°）	Breaking strength retention （%）	whiteness
Untreated	—	—	—	203	184	100	84.3
1	80	150	2	233	211	94.1	82.6
2	80	160	3	240	218	91.5	81.5
3	80	170	4	252	235	89.4	81.2
4	100	150	3	268	252	91.2	81.4
5	100	160	4	270	253	89.6	80.8
6	100	170	2	258	244	89.7	79.2
7	120	150	4	270	258	89.4	80.5
8	120	160	2	267	249	91.6	82.1
9	120	170	3	274	257	87.7	77.4

The result of orthogonal test is analyzed, considering the dry, wet recovery angle, whiteness and breaking strength retention can be optimized finishing condition: The optimal concentration of both finishing agent Y and magnesium chloride was 100g/L. The optimal baking temperature and baking time were 160 ℃ and 3min, respectively.

Application performance comparison

The optimum process for silk habotai finishing, Y and JY08 (the main composition is BTCA)) anti-crease finishing agent were compared, The optimal concentration of both finishing agent JY08 and magnesium chloride was 100g/L. The optimal baking temperature and baking time were 160 ℃ and 3min, respectively.

Table 2 Comparison of application performance of finishing agent Y

finishing agent	DWRA（°）	WWRA（°）	Breaking strength retention（%）	whiteness
Untreated	203	184	100	84.3
finishing agent Y	270	253	89.6	80.8
JY08（BTCA）	283	262	82.5	81.7

It is shown in table 2 that anti-crease finishing agent Y dry, wet anti-crease performance is slightly lower than the JY08, but the breaking strength retention rate is better than the JY08.The Y is a kind of polycarboxylic acid anti-crease finishing agent, the silk fabrics treated by finishing agent Y had high strength retention and washing fastness. In addition, the effect of ant-crease finishing on the whiteness of fabrics was small.

Finishing agent Y washing fastness test

After finishing of silk fabric washing fastness test results are shown in table 3.

Table 3 Finishing agent Y washing fastness test

Washing times (time)	DWRA（°）	WWRA（°）	whiteness
0	270	253	80.8
10	272	254	80.6
20	268	249	81.0
30	265	245	80.9
50	261	242	80.5

We can see from table 3, After finishing of silk fabrics, washed 50 times with water, dry and wet recovery angle decreases a little. Silk habotai still has good performance of anti-crease, whiteness has a little change, so it is a durable anti-crease finishing agent.

Conclusion

1) The Y is a kind of polycarboxylic acid anti-crease finishing agent, the optimum process conditions were as follows: The optimal concentration of both finishing agent Y and magnesium chloride was 100g/L. The optimal baking temperature and baking time were 160 ℃ and 3min, respectively.

2) compared with JY08, anti-crease finishing agent Y dry, wet anti-crease performance is slightly lower than the JY08, But the results show that the silk fabrics treated by finishing agent Y had high strength retention and washing fastness. In addition, the effect of ant-crease finishing on the whiteness of fabrics was small.

3) After finishing of silk fabrics, washed 50 times with water, dry, wet recovery angle decreases a little. Silk habotai still has good performance of anti-crease, whiteness has a little change, so it is a durable anti-crease finishing agent.

Keywords: sheet metal forming; strain analysis; thickness reduction rate; forming limited diagram

Abstract. An experimental study is conducted to explore a new method to calculate the strain in axisymmetric workpiece forming. When designing deep drawing die for an axisymmetric workpiece, the principal strain during the forming is needed to estimate formability and to decide whether the forming is finished in one pass. Strain calculation is a difficult task, so an ideal same area method used to calculate the strain for an axisymmetric workpiece along with a correction same area method considered thickness reduction rate is proposed here. The deep drawing test for an axisymmetric workpiece is used to obtain the strain along circumference and generatrix direction. The strain along the two directions calculated by the ideal same area method and correction same area method is compared with experimental results. The results show that ideal same area method can be used to calculate the strain during the forming process for an axisymmetric workpiece and the result from correction same area method is close to the experiment.

Introduction

Sheet metal forming operations having high productivity are generally employed in the production of aircraft parts, automotive workpieces, electric appliances, etc. For sheet metal products with complex geometry, if the deformation in single stage forming is larger than the maximum allowable deformation of the material, the product needs to be manufactured by multi-pass forming process to prevent the occurrence of defects such as necking, wrinkling and cracking [1, 2].

The forming limit diagram (FLD) is used in sheet metal forming to determine how susceptible sheet metal is to tearing when it is formed into a product shape in a stamping process. The concept of the FLD was found by Keeler and Backofen and Goodwin to research the formability of sheet metals [3, 4]. Both the strain-based FLD and the stress-based FLD are forming limit diagrams and the strain-based FLD is often used in sheet metal forming. The path of the forming limit is called the forming limit curve (FLC) and is the key feature of FLD [5, 6]. The distance between the FLC and all of the measured or predicted strain throughout the forming part characterize the degree of safety. The concept of FLD is widely applied to metal forming process [7, 8]. It is important to get the FLC of material and strain throughout the forming part. The principal strain in sheet plane is used to decide its forming state through FLD. The two kinds of principal strain in a position of forming part taken as two coordinates of a point in FLD. For an axisymmetric workpiece, the principal strain is the strain in the circumference direction and the generatrix direction. The relative position between strain point and the FLC determines the formability in this position of the forming part. Strain calculation and analysis is a difficult task. For half a century, considerable efforts have been devoted to explore new methods for determining strain. Among these methods, experimental method and simulation method are the mainstream. Grid method is popularly used in experiment

processes, and the circle grid is widely applied for its simpleness and convenience. With the development of computer technology, finite element simulation becomes an important method to calculate and analyze strain during forming process. For instance, Mohebbi used the finite element simulation method to analyze strain in flow forming of tubes [9]. Additionally, Tszeng investigated ring rolling process by strain finite element method analysis [10]. A modified method to obtain the principal strain for an axisymmetric workpiece is discussed in this paper.

Strain Calculation

Ideal Same Area Method

Before the possibility of multi-pass deep drawing process is assessed, we must determine whether the degree of deformation that parts require is larger than the maximum allowable degree of deformation of the material during the forming process of the axisymmetric workpiece. The situation of deformation degree in sheet metal forming can be expressed by three kinds of principal strain—circumference direction strain, generatrix direction strain, and thickness direction strain, and all of them have to be calculated before making the forming scheme and designing the die.

Fig.1 is an axisymmetric workpiece and Fig.2 is the blank used to form the axisymmetric workpiece. The workpiece has same volume with the blank in sheet metal forming according to the plasticity theory. If the workpiece thickness does not change during forming, it will have the same outside surface area as the blank. The axisymmetric workpiece surface is divided into n portions as shown by Fig.1， and the distance along generatrix direction for every portion is same. The area of every portion can be determined using CAD. Similarly, the blank is divided into the same number of sections. The portions are numbered by 1 to n from center to the outside boundary in axisymmetric workpiece and blank. The same number portions in axisymmetric workpiece and blank have same area.

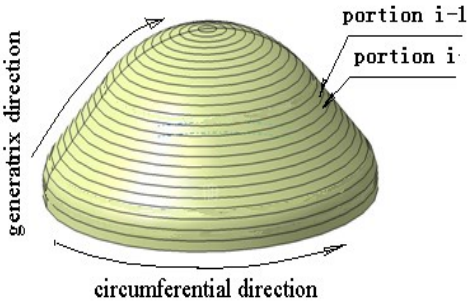

Fig.1 Workpiece

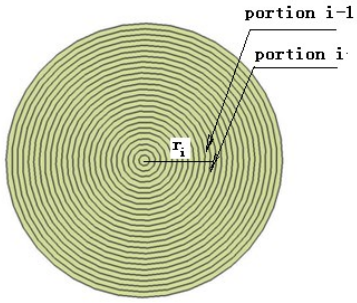

Fig.2 Blank

Here

i is a serial number, A_{w_i} is the area of portion i in workpiece and A_{b_i} is the area of portion i in blank. Then

$$A_{w_i} = A_{b_i}. \quad (1)$$

$$A_{w_1} + A_{w_2} + ... + A_{w_{i-1}} + A_{w_i} = A_{b_1} + A_{b_2} + ... + A_{b_{i-1}} + A_{b_i}. \quad (2)$$

The A_{w_1}, A_{w_2},..., A_{w_i},... can be obtained from the workpiece CAD model, and from that $A_{b_1}, A_{b_2},..., A_{b_i},...$ are known quantities. The radius used to express boundary line in blank can be calculated by the below formula.

$$r_i = \sqrt{(A_{b_1} + A_{b_2} + ... + A_{b_{i-1}} + A_{b_i})/\pi}. \quad (3)$$

To calculate circumferential direction strain and generatrix direction strain, we use the equation below.

$$\varepsilon_{g_i} = (\Delta L - (r_i - r_{i-1}))/(r_i - r_{i-1}). \quad (4)$$

$$\varepsilon_{c_i} = (a_{1_l} - 2\times 3.14159\times r_i)/(2\times 3.14159\times r_i). \quad (5)$$

Here,

ΔL is the distance along generatrix direction for per portion in axisymmetric workpiece. It is given before dividing workpiece.

a_{1_l} is the maximum boundary circumference of portion i in axisymmetric workpiece. It can be obtained from the CAD model of workpiece .

Correction Same Area Method

There is some change in thickness during sheet metal forming. The change in thickness can have an influence on ε_{g_i}, ε_{c_i} calculated in same area method. The volume of sheet metal workpiece keeps constant during forming.

Then

$$A_{w_i} \times t_{w_i} = A_{b_i} \times t_{b_i}. \quad (6)$$

Here,

A_{w_i} is the area of outside surface in portion i for axisymmetric workpiece. A_{b_i} is the area of outside surface in portion i for blank. t_{w_i} is thickness in portion i for axisymmetric workpiece. t_{b_i} is thickness in portion i for blank.

Then,

$$A_0 = At/t_0 = A[1-(t_0 - t)/t_0]. \quad (7)$$

Here,

$(t_0 - t)/t_0$ is thickness reduction rate.

If the average thickness reduction rate η_i in per portion is considered, then the correction radius used to express boundary line in blank can be calculated using the below formula

$$r_{c_i} = \sqrt{A_{b_1}(1-\eta_1) + A_{b_2}(1-\eta_2) + ... + A_{b_{i-1}}(1-\eta_{i-1}) + A_{b_i}(1-\eta_i)/\pi}. \quad (8)$$

When the average thickness reduction rate η_i per portion is taken into account, the circumference direction strain and generatrix direction strain can be calculated using the following equations.

$$\varepsilon_{cg_i} = [\Delta L - (r_{c_i} - r_{c_{i-1}})]/(r_{c_i} - r_{c_{i-1}}). \quad (9)$$

$$\varepsilon_{cc_i} = (a_{1_i} - 2\times 3.14159\times r_{c_i})/(2\times 3.14159\times r_{c_i}). \quad (10)$$

Experiment

The workpieces shown as Fig.3 are formed by deep drawing. Six test pieces are used in each experiment and the average value is obtained. Grid method is used in this experiment to study the distribution. Grid printed on the blank was done using the circle grid analysis technique [11]. Then

the strain level and distribution is obtained by measuring and analyzing the change after the deformation. The grid on the blank is a circular shape having diameter of 3 mm as shown in Fig.4. After the deformation, the grid turns to ellipse shape, and the strain in two principal directions can be calculated by measuring the strain along the major and minor axes of the ellipse.

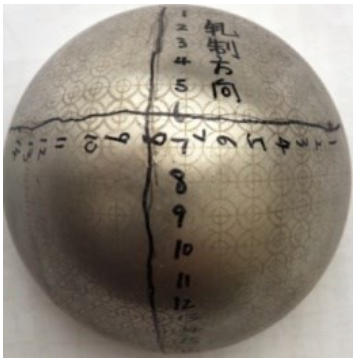

Fig.3The Arc intermediate shape test piece

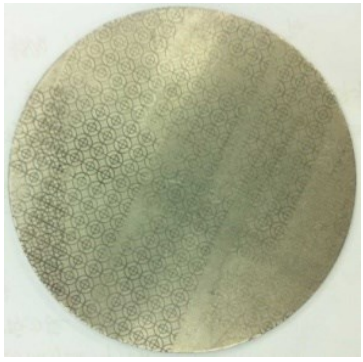

Fig.4 The blank with grid

Results

The generatrix and circumferential direction strain distribution for the workpiece shown as Fig.1 are calculated by ideal same area method and correction same area method respectively. The average thickness reduction rate η_i in each portion is used in correction same area method come from finite element analysis for the workpiece. The calculated and experimental strain results are plotted in Fig.5 and Fig.6. The blue curve is the strain form experiment. The red curve is the strain form ideal same area method. The yellow curve is the strain form correction same area method. The strain curves from ideal same area method, correction same area method, and experiment have the same trend， and the results from correction same area method are close to the experimental results. The results far from the center of the workpiece have larger differences between ideal same area method and experiment.

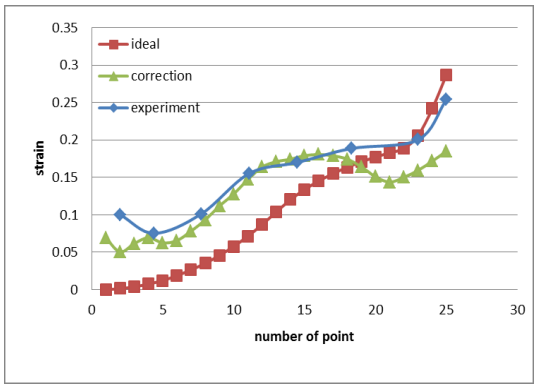

Fig.5 The generatrix direction strain distribution

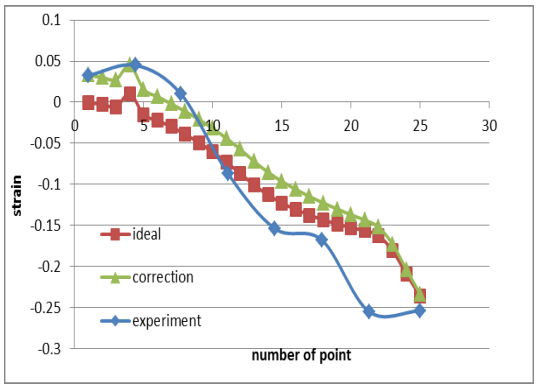

Fig.6 The circumference direction strain distribution

Conclusions

The ideal same area method and correction same area method have been put forward. The results calculated by the ideal same area method and correction same method compared with experiment. The conclusions are as follow:

1) An ideal same area method is proposed for the calculation of the principal strain along circumferential direction and generatrix direction. The strain can be used to forecast formability when we design deep drawing die.

2) A correction same area method is proposed for the calculation of the principal strain along circumferential direction and generatrix direction. The average thickness reduction rate η_i in each portion is taken into account in the strain calculation. We can obtain the average thickness reduction rate η_i in each portion through finite element analysis or experiments.

3) The data on strain obtained from the deep drawing forming experiment show that the strain curve from correction same area method is close to the experimental strain curve.

Keywords: Down Coiler; BP Neural Network; Coiling Torque; Forecast

Abstract: Down coiler is an important equipment of hot rolling mill. The coiling torque is changing constantly in the process of strip steel coiling, and the largest coiling torque depends on several factors, such as the material and specification of coiling strip, the coiling temperature and the process parameters and so on. Only when the largest coiling torque is less than the carrying capacity could the coiler work in security. A topology relationship of the largest coiling torque among the materials, the specification of the strip and the coiling temperature is established. Based on the BP(backward propagation of errors) artificial neural network, a predicted formula model of the largest coiling torque in coiling high strength strip is built, which provides a theoretical basis for the development and utilization of the largest working potential of the down coiler.

Introduction

The down coiler, usually used for coiling strips extracted from a finishing mill, is consists of side guides, a pinch roll, a mandrel, and wrapper rolls, as illustrated in Fig.1.

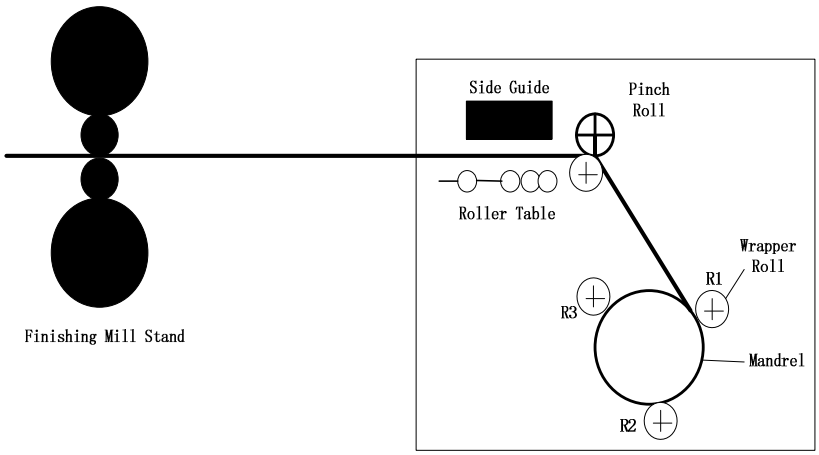

Fig.1 Diagram of a down coiler

The down coiler plays an important role in the hot strip mill lines. And the coiling torque of down coiler will affect the quality of the strip steel directly[1]. But it is affected by many complicated and non-linear factors such as coiling temperature, material and specification of strip steel, which often make the largest coiling torque difficult to forecast. As there is no method for forecasting the largest coiling torque accurately and effectively at the moment, scientists have done a lot of calculation, mostly based on empirical formula[2].

The successful application of artificial neural network in many fields provides a good method for the forecast of the largest coiling torque of down coiler recently. The artificial neural network model, with the good nonlinear fitting ability and efficient method of learning, has been more widely used in the field of data prediction. In this paper, BP neural network is used for forecasting

the largest coiling torque of down coiler. The accuracy of forecasts will be largely improved and it will ensure the safety of the down coiler as well as the quality of strip steel.

The establishment of BP neural network model

An artificial neural network is consisted of an interconnected group of artificial neurons, and it processes information using a connectionist approach. ANN(artificial neural network)is an adaptive system and non-linear statistical data modeling tool, which could exactly reflect characteristics of a system[3].

Determination of influencing factors of coiling torque

In order to derive a dynamic equation for strip coiling, it is important to ensure the required load torques for activating the mandrel. There are three kinds of torque: M_T for the strip tension, Mw for bending the strips, M_d for the rotational deceleration of the mandrel resulting from the increasing outside diameter of the coil[4].

$$M_T = \frac{1}{2} \times U_T \times h \times b \times D(t) \tag{1}$$

Where U_T is the unit tension of strip, h is the thickness of strip, b is the width of strip, D(t) is the coil diameter of strip.

$$M_w = \frac{1}{4} \times \sigma_s \times b \times h^2 + \frac{1}{60 \times D(t)} \times \sigma_s \times b \times h^3 \tag{2}$$

Where σ_s is the hot yield stress.

$$M_d = I \times \frac{C_{RPM}(t)}{T_i} \left\{ C_{RPM} = \frac{d}{dt} \left(\frac{\pi}{60} \times D(t) \right) \right\} \tag{3}$$

Where $C_{RPM}(t)$ is the rotate speed of the mandrel, T_i is the coiling time, I is the total inertia.

The total load torques M for strip coiling is shown as following：

$$M = M_T + M_w + M_d \tag{4}$$

As the above formula shown, coiling torque is mainly influenced by the thickness, the width, and the yield strength of the strip steel. In addition, the performance of strip steel is related to the temperature of coiling steel. Therefore the coiling torque is mainly determined by the four above factors.

BP neural network model

Neural network, as a nonlinear complex system, is composed of a large number of simple processing units (or neurons) which extensively interconnect[5]. BP neural network with three layers and sigmoid activation function is used for the model.[6].

In the system of forecasting coiling torque, there are four input parameters, which are the most affecting factors of the largest coiling torque. The principle of forecast of neural network is described by a 4-4-1 ANN with the hidden layer composed four units. The structure of the artificial neuron model is shown in Fig 2.

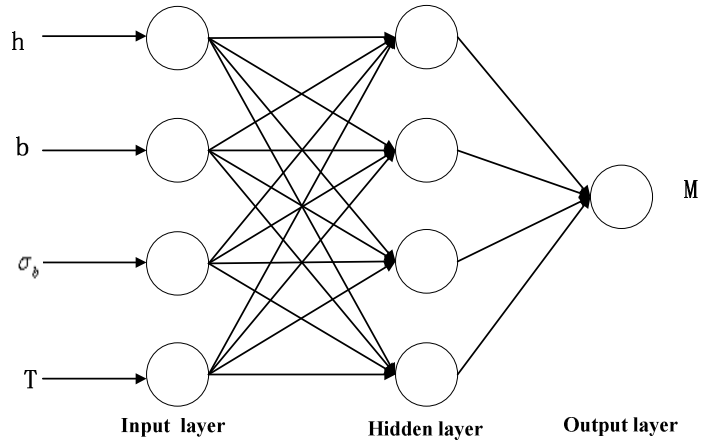

Fig.2. The structure of the artificial neuron model

The input of the input layer:

$$\{x_r\} = \begin{Bmatrix} x_r(1) \\ x_r(2) \\ x_r(3) \\ x_r(4) \end{Bmatrix} = \begin{Bmatrix} h \\ b \\ \sigma_b \\ T \end{Bmatrix} \tag{5}$$

Where X_r is the unit value of the input layer, h is the thickness of the strip, b is the width of the strip, σ_b is the tensile strength of the strip, T is the temperature of the strip.

The output of the output layer:

$$\{ y \} = \{ M \} \tag{6}$$

Where y is the predictive value of output layer, M is the largest coiling torque.

Selection of transition function

BP Network is able to access any curve,which requires the transition functions tobe differentiable all the time.The hidden layer of this paper adopts hyperbolic tangent function of the S type transmission function—Tansig. Meanwhile, the output layer adopts a linear transfer function--Purelin.

Obtainment of the training sample

By collating and analyzing the testing data, the largest coiling torque is recorded in different coiling temperature and different strips in thickness, width and yield stress for BP network testing samples. A total number of 28 groups of testing samples was used. The coiling temperature of which is between 500 and 700 Celsius, and the thickness of strips ranges from 3.5 to 16 mm, the width is 1043 to 2065mm, while the yield stress is from 280 to 920MPa.Generally speaking, various types of strip steel are covered in the 28 groups testing sample.

Realization of the neural network model

Normalization of the training sample

A unipolar Sigmoid function is used for the activation function, which needs to unify dimension of different parameters in each sample. Single node data mapping mode (SNDM) is taken to normalize the input data of the neural network. The normalized conversion formula is shown as follow:

$$x_{ri}=(x_{si}-\min(x_{si}))/(\max(x_{si})-\min(x_{si})) \quad (7)$$

Where x_{ri} is sample value of i-th unit in the input layer, x_{si} is the normalized scaled value

Initialization of the input value

Quantification of conjugate gradient method is adopted for training function; The initial vector of each connection weight in hidden layer as well as output layer should be protocol selected as 0.05;the largest times of training is set to 2000;the accuracy requirement of training is set to 0.009.

Training results of BP neural network model

28 samples of measured value are input into the BP Neural Network model. The comparison of the 28 samples between measured value and the predicted value are showed in Fig 3.The error of training process is showed in Fig 4.Parts of the sample value and predicted value are showed in Table1.As the Fig 4 shows, when the number of training times reaches to 400, the predictive value could reach the expected target. Fig 3 shows that predicted value are nearly the same as the measured value after training, and further calculation shows that the error ranges from 0.01%to 5.60%, only 2 samples are out of the range. This shows that the trained BP neural network model reaches the expect effect and the built model could be used to predict the largest coiling torque of down coilers accurately and effectively.

TABLE 4. THE THRESHOLD VALUE IN THE OUTPUT LAYER

θ_c	j=1
	0.8592177

The relationship between the various units in the hidden layer and the input layer:

$$x_{cj}=\mathrm{tansig}\left(\sum_{i=1}^{4} w_{ij}x_{ri}-q_{ri}\right) \tag{8}$$

$$\mathrm{tansig}(x) = \frac{2}{(1+e^{-2x})}-1 \tag{9}$$

The relationship between the various units in the hidden layer and the output layer:

$$y=\mathrm{purelin}\left(\sum_{j=1}^{4} w_{cj}x_{cj}-\theta_c\right) \tag{10}$$

$$\mathrm{purelin}\ (x) = x \tag{11}$$

The largest coiling torque is obtained from the equation:

$$M = y \times (182.1 - 101.7) + 101.7 \tag{12}$$

A part of the predicted value is shown in Table 6:

TABLE 3. PREDICTED VALUE TABLE OF THE LARGEST COILING TORQUE

No	h(mm)	b(mm)	σ_b (Mpa)	T(℃)	M (kN·m)
1	5.5	1100	280	600	152.4
2	13	1830	920	550	160.2
3	6	1280	280	695	114.4
4	8	1600	510	600	153.9
5	18.4	1550	910	500	204.4

Conclusion

In this paper, a neural network model for forecasting the largest coiling torque of down coilers was established based on back propagation algorithm. Compared with the measured value and predicted value, the relative error is in the 5.60%.The errors satisfy the requirement of practical application. The results demonstrated that the forecast of the largest coiling torque was accurate and effective. The largest coiling torque of different kinds of strip steels could be forecasted. Moreover, the accuracy of forecasts will be largely improved and it will ensure the safety work of the down coiler as well as the quality of strip steel.

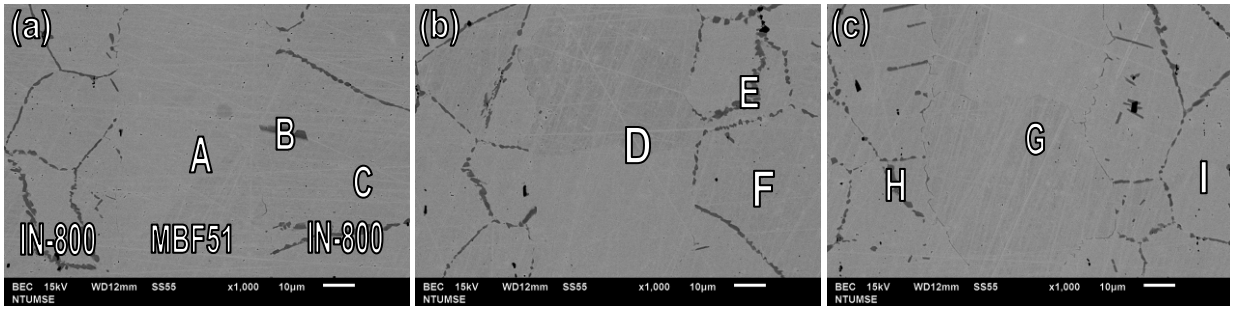
Keywords: Brazing, Incoloy 800, Nickel Base Filler, Microstructure, Shear Strength

Abstract: The purpose of this research is focused on developing a reliable plate heat exchanger made by Incoloy 800 (IN-800) alloy featured with high corrosion resistance in order to replace the current Cu brazed plate heat exchanger made by the 316 stainless steel. A Ni-based filler, MBF-51, was applied to braze the plate heat exchanger made by IN-800. According to the brazing optimizing experiments, the successful brazed joint was made by brazing at 1170 ^{o}C for 1800 s. Better shear strength is achieved from the specimen brazed at 1120 ^{o}C for 1800 s.

Introduction



The technology of manufacturing plate heat exchanger is much more difficult than that of making traditional heat exchanger. The plate heat exchanger is currently made by Cu brazed 304/316 stainless steel(s) for most major heat exchanger manufacturer in the world [1]. Stable brazing process and inexpensive filler alloy are primary advantages of Cu brazing. However, requirements of increased corrosion resistance, avoiding Cu ion contamination, resisting to high temperature and pressure resulting from various users make the Cu brazed stainless steel plate heat exchanger failed to satisfy all demands. Other materials such as Inconel 625 and commercially pure Ti currently applied in manufacturing plate heat exchangers for special purpose are suffered from high cost and/or insufficient pressure resistance [2-4]. Therefore, it is crucial to develop high-performance plate heat exchangers applied in next generation.

Incoloy 800 (IN-800) is a Fe/Ni-based alloy, and its chemical composition in weight percent is 44.5 % Fe, 21 % Cr, 0.4 % Al, 0.4 % Ti, 0.8 % Mn, 0.5 % Si, 0.4 % Cu and Ni balance [5]. It is widely used in furnace and heat exchanger parts due to its high corrosion resistance and moderate creep strength [5]. Additionally, its price is much cheaper than that of Inconel 625 alloy. IN-800 alloy is a good choice to produce the plate heat exchanger. The MBF-51 foil is a modified Ni-based braze alloy, and its chemical composition in weight percent is 15 % Cr, 7.3 % Si, 1.4 % B and Ni balance [2]. Compared to traditional Ni-based braze alloys, the boron content in MBF-51 filler has been greatly decreased in order to diminish the amount of brittle boride precipitates in the brazed joint [2, 6-9]. Therefore, it has been selected as the brazing filler metal in the experiment.

Experimental Procedures

IN-800 alloy is used as the base metal with the dimension of 15 mm in length, 6 mm in width and 3 mm in thickness. All IN-800 plates were ground by SiC papers up to grit 600 and subsequently cleaned in ultrasonic bath using acetone solution prior to brazing. The thickness of MBF-51 filler foil is 40 μm. Because liquidus temperature of MBF-51 foils is 1126 ^{o}C, vacuum furnace brazing under the vacuum of 5×10^{-5} mbar was performed at 1170, 1185, 1200 ^{o}C for 900, 1800, and 3600 s, respectively. The heating rate was set at 0.33 ^{o}C/s, and all specimens were preheated at 1000 ^{o}C for 600 s prior to brazing. Cross-sections of brazed joints were cut by a low-speed diamond saw and examined by using a JEOL JSM 6510 scanning electron microscope (SEM). A JEOL 8600SX electron probe microanalyzer (EPMA) equipped with the wavelength dispersive spectroscopy (WDS) was utilized for quantitative chemical analyses of various phases in the brazed joint. Its operation voltage was 15 kV, and the minimum spot size was set at 1 μm.

Shear tests were performed to evaluate the bonding strength of the brazed joint [2,10]. The specimen was compressed by a Shimadzu AG-10 universal testing machine with a constant speed of 0.0167 mm/s. There are at least three specimens were measured for each brazing condition. Failure analyses of fractured surfaces after shear tests were conducted using the SEM secondary electron images (SEIs). Cross-sections of brazed joints after shear tests were inspected using SEM backscattered electron images (BEIs) in order to locate fracture locations of the joints.

Location / Phase	Al	B	C	Cr	Cu	Fe	Mn	Ni	Si	Ti
A (Cr/Fe/Ni-rich matrix)	0.5	0.4	0.1	19.1	0.1	16.6	0.4	54.3	8.2	0.2
B (boride)	0.1	22.1	0.5	48.1	0.0	21.8	0.6	6.6	0.2	0.1
C (Cr/Fe/Ni-rich matrix)	0.9	1.4	0.3	22.3	0.1	45.5	0.8	27.8	0.6	0.3

Fig. 1 EPMA BEIs and WDS chemical analysis results of IN-800/MBF-51/IN-800 joints brazed at (a) 1170, (b) 1185, and (c) 1200 ^{o}C for 1800 s.

Results and Discussion

Fig. 1 displays EPMA BEI and WDS chemical analysis results in atomic percent of IN-800/MBF-51/IN-800 joints brazed at 1170, 1185, and 1200 ^{o}C for 1800 s. At least two phases are readily observed from the brazed joint, including Cr/Fe/Ni-rich matrix as marked by A, C, D, F, G, I and boride mainly containing B, Cr, Fe as marked by B, E, H. The Cr/Fe/Ni-rich matrix is alloyed with approximately 20 % Cr. It is expected that the brazed joint is corrosion resistant. Based on the Fig. 1, the interfacial reaction between the molten braze and IN-800 substrate is primarily along grain boundaries of IN-800 alloy. It is difficult to quantify interfacial lengths based on SEM images. Because the growth of interfacial thickness is diffusion controlled, especially along grain boundaries, there is no sharp interface between the braze and IN-800 substrate. The fact of borides primarily existing along grain boundaries is consistent with previous studies using Ni-based braze alloys [2,7,11].

Fig. 2 displays microstructural evolution of IN-800/MBF-51/IN-800 joints under various brazing conditions. The width of MBF-51 brazed joint is slightly increased with increasing the brazing temperature. Increasing the brazing temperatures and/or time also enhance the penetration depth of grain boundary borides. However, higher brazing temperature and/or longer brazing time cannot remove grain boundary borides from the joint. On the contrary, grain boundary borides are slightly coarsened with increasing the brazing temperature and/or time.

TABLE 1 AVERAGE SHEAR STRENGTHS OF SELECTED BRAZED JOINTS

Filler Metal	Brazing Temperature (K)	Brazing Time (s)	Average Shear Strength (MPa)
MBF-51	1170 ^{o}C	1800	366
MBF-51	1200 ^{o}C	1800	Yielding of IN-800 Substrate

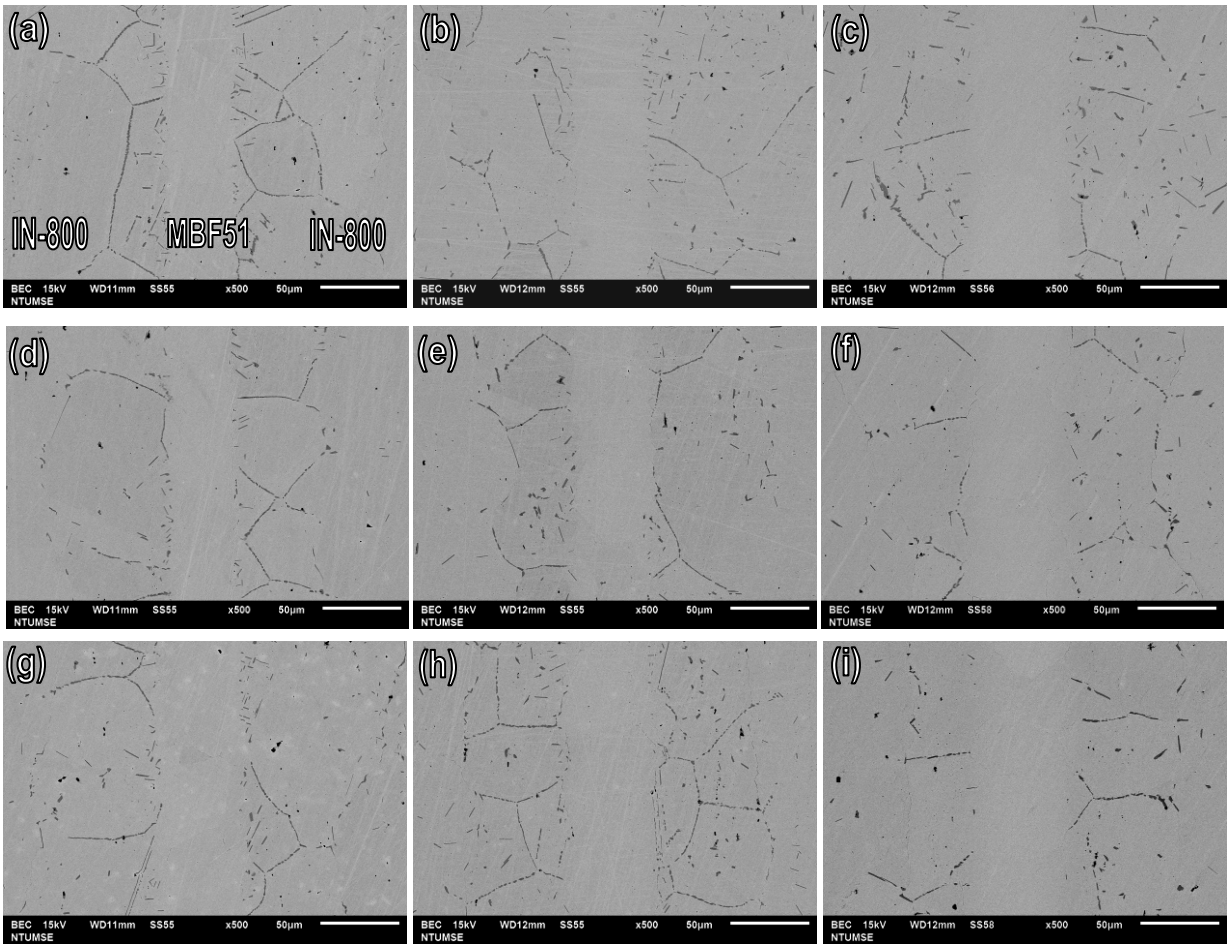

Fig. 2 EPMA BEIs of IN-800/MBF-51/IN-800 joints brazed at (a) 1170 ^{o}C for 600 s, (b) 1170 ^{o}C for 1800 s, (c) 1170 ^{o}C for 3600 s, (d) 1185 ^{o}C for 600 s, (e) 1185 ^{o}C for 1800 s, (f) 1185 ^{o}C for 3600 s, (g) 1200 ^{o}C for 600 s, (h) 1200 ^{o}C for 1800 s, (i) 1200 ^{o}C for 3600 s.

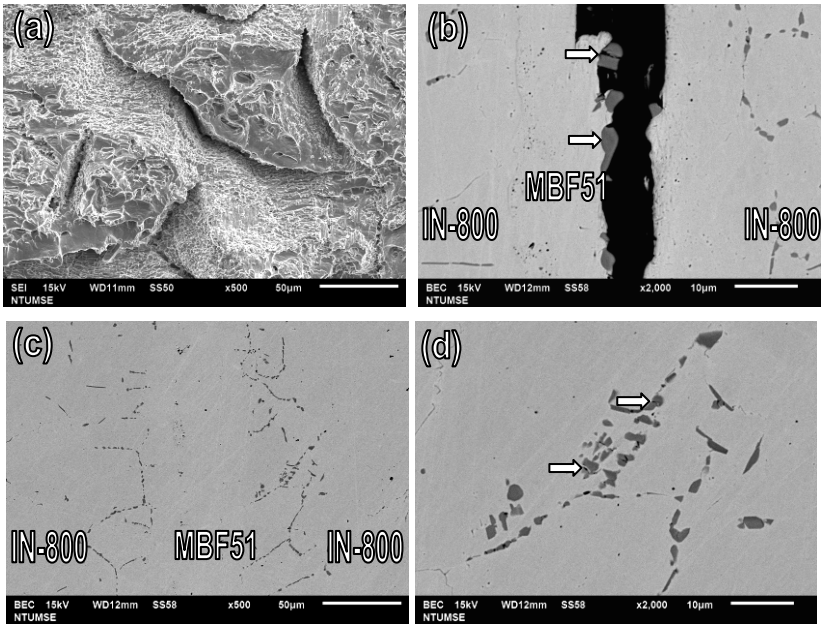

Fig. 3 SEM failure analyses of fractured IN-800/MBF-51/IN-800 joints after shear tests: (a) SEI fractograph, (b) BEI of fracture location brazed at 1170 ^{o}C for 1800 s; (c, d) BEIs of the cross section brazed at 1200 ^{o}C for 1800 s.

Table 1 displays average shear strengths of selected IN800/MBF-51/IN-800 brazed joints. The joint brazed at 1170 ^{o}C for 1800 s has the average shear strength of 336 MPa. In contrast, the brazed joint is not fractured even yielding of the IN-800 substrate for the specimen brazed at 1200 ^{o}C for

1800 s. Fig. 3 shows SEM failure analysis results of fractured IN-800/MBF-51/IN-800 joints after shear tests. For the specimen brazed at 1170 ^{o}C for 1800 s, quasi-cleavage dominated fractograph is observed from Fig. 3(a). The crack is initiated from the grain boundary boride as demonstrated by arrows in Fig. 3(b). The presence of continuous grain boundary boride is detrimental to bonding strength of the brazed joint. For the specimen brazed at 1200 ^{o}C for 1800 s, grains of the brazed joint is distorted (Fig. 3(c)), and a few grain boundary borides are fractured as indicated by arrows in Fig. 3(d).

Summary

Furnace brazing IN-800 alloy using the MBF-51 foil has been investigated in the experiment. The brazed joint mainly comprised of grain boundary borides and Cr/Fe/Ni-rich matrix. The Cr/Fe/Ni-rich matrix is ductile as compared with grain boundary borides. The presence of continuous grain boundary borides deteriorates bonding strength of the joint. The average shear strength of IN-800/MBF-51/IN-800 joint brazed at 1170 ^{o}C for 1800 s is 366 MPa. Increasing the brazing temperature to 1200 ^{o}C is beneficial to its shear strength. Because wide brazing process window is achieved, it shows the potential for industrial application.

Keywords: water-granulated nickel slag; cementitious materials; back-filling method; chemical activation

Abstract. The back-filling method is distinguished from other mining methods by its higher cost. In order to solve this problem and utilize water-granulated nickel slag as much as possible, nickel slag from flash smelting operation was used to prepare cementitious materials for backfilling. Approaches including mechanical activation and chemical activation were adopted to improve the cementitious activity of the slag. By taking the strength of the backfill materials as the evaluation standards, the hydration activity and cementitious performance of the slag were investigated under different activation conditions, and the mechanism of chemical activation was analyzed. The results shows that cementing agent prepared by using mainly the slag (occupying 85% of the total raw materials) can be used to replace cement and meet the production requirements for backfilling materials.

Introduction

The increasingly more attention to the environmental pollution, the greatly improved mining and cementing agent technology, help foster the cemented backfilling mining to become a modernized mining technology characterized with its high efficiency, high strength and high recovery rate[1]. Traditionally, cemented filling generally uses Portland cement as cementitious materials (cementing agent). According to the statistics of the mines using back-filling method in China[1], cemented filling accounts for 25%~40% of the total cost of mining, and cementing agent accounts for 70%~80% of the cemented filling cost. Therefore, taking suitable measures and developing proper cement substitute will have important meaning to reduce the filling cost and extend the application field of the filling mining technology [2, 3].

At present, lots of work has been done on the research of cement substitute, for instance, fly-ash was used to replace cement directly through adding partially based on its volcano ash activity [4-7], and slag was used to partially or completely replace cement after grinding and chemical activating [8-10]. As a kind of granular material with latent hydraulic activity, slag is somewhat similar to Portland cement in the chemical and mineral composition, therefore, it has a great potential to be used as cementitious material. The research on slag cement has a history of thirty years, and slag cement has been widely used in China. However, because of the peculiarity of the mine filling operation, less research on using slag as the main component of cementing agent has been done.

Since the late 90's of the last century, the Jinchuan Group Co. Ltd. (JGCL, Gansu Province, China) began to apply paste filling technology which backfill materials was produced by using cement as cementing agent, which means large amounts of cement has to be bought every year. Practice in JGCL has proved that the cement dosage and slurry concentration of the filling material are the main factors affecting the filling cost and the strength of the filling materials [11]. Therefore, if the slag of JGCL could be used to produce cementitious material, quite amount of money used to buy the cement would be saved. It could not only improve the economic efficiency of the enterprise, but also alleviate the land occupation and environmental pollution caused by slag discharge. This paper mainly focuses on the methods of using the water-granulated nickel slag of JGCL as the main raw material to produce exclusive cementitious material and the cementing mechanism of the slag.

Experiment

Experimental materials.

Water-granulated nickel slag: the slag whose chemical constituents mainly include SiO_2, CaO, MgO, etc. (Table 1) was fromJGCL. It is a second water-granulated slag produced by the technology extracting iron from the flash smelting slag (original slag). In addition to a small amount of pyroxene, $2CaO \cdot SiO_2$ and olivine, 80%~90% of the slag is glass phase, so it has a certain degree of potential activity. However, compared with the ordinary Portland cement, it cannot be directly used as cementitious material because of its low CaO content, high SiO_2 content, and relatively low activity coefficient (Al_2O_3/ SiO_2). It has to be activated by mechanical or chemical activation.

Activating agent: including natural gypsum, calcium carbide slag, anhydrous sodium sulfate, cement clinker. The composition of the activating agents is shown in Table 1.

Rod-milling sand: a kind of sang from the neighbourhood of JGCL, having -3mm granular size, used as filling aggregate.

Table 1 Chemical composition of water-granulated nickel slag and activating agents [wt%]

Raw materials	SiO_2	Al_2O_3	CaO	MgO	Fe_2O_3	FeO	K_2O	Na_2O	SO_3	Other	Loss
Water-quenched nickel slag	36.62	6.97	22.69	28.81	0.27	3.01	0.15	0.16	0.35	0.33	-0.38
Carbide slag	4.09	2.16	67.09		0.04	0.36		0.28	0.14		25.84
Desulfurized gypsum	3.16	1.35	33.38	7.49	0.47	0.09			45.70	0.08	8.28
Cement clinker	22.50	4.86	66.30	0.83	3.43	0.02			0.31	0.79	0.96
Sodium sulfate								43.23	55.77	0.008	0.002

Experimental methods.

The dried water-granulated nickel slag was milled by using Φ500×500 test mill (mechanical activation), then it was mixed with activating agents according to pre-designed mixing ratio. The mixture and rod-milling sand were poured into a mortar stirring pot at a ratio of 1:4, and enough water was added to guarantee that the materials were under standard consistence. The materials were stirred for reasonable time according to the standards of GB/T50080-2002, then poured into a standard cement mortar mold (40mm×40mm×160mm). The mold was placed on cement mortar shaking table and the materials was compacted and molded by tamping vibration, then they were put into curing box and steam-cured under the temperature of 45±1℃ and relative humidity of 97±1%. When the curing time reached 24 hours, the specimen was demoulded. The demoulded specimen was continuously cured for 7 days and 28 days respectively in standard curing box, and then its strength was tested.

Results and discussion

Effect of mechanical activation on backfill materials strength.

Precious research showed that the hydration activity of cementitious material can be improved by increasing the specific surface area through mechanical grinding [10]. After the water-granulated nickel slag was ball-milled 40, 60, 80, 100, 120, 140, 160 and 180 min respectively, the specific surface area was 215, 320, 490, 565, 620, 705, 770 and 800 $m^2 \cdot kg^{-1}$. The milled slag was used as cementing agent and mixed with rod-milling sand at ratio of 1:4, then the mixture was made into backfill materials with slurry concentration of 79%. The backfill material was steam-cured for 24 hours and then cured for 7 days and 28 days in curing box. The strength of the backfill material was tested respectively and the results are shown in the Fig. 1.

Fig. 1 shows that the strength of the backfill material increases with the growth of the specific surface area. When the specific surface area of the slag increases from 490 $m^2 \cdot kg^{-1}$ to 620 $m^2 \cdot kg^{-1}$, the compression strength exhibits fastest growing. When the specific surface area is over 620 $m^2 \cdot kg^{-1}$, the compression strength grows slowly. Considering comprehensively strength of backfill material and grinding cost of the slag, the best grinding time should be 120 min (accordingly, the specific surface area is 620 $m^2 \cdot kg^{-1}$), and at that time the corresponding compression strength of the backfill material cured for 7d and 28d is 2.2 MPa and 3.3 MPa respectively.

Effect of chemical activity on the performance of backfill material.

The above grinding experiment shows that mechanical activity can activate the potential activity of water-granulated nickel slag to a certain extent, but not distinctively, and the strength of the backfill material can't meet the requirement of backfill operation. Therefore, further experiment on chemical activating was carried out. In order to explore the effect of activating agent on nickel slag backfill material, desulfurized gypsum and carbide slag were selected as the main activating agents and sodium sulfate and cement clinker as the supplementary activating agents.

Effect of the main activating agents on the strength of backfill material.

To determine the best ratio of desulfurized gypsum and carbide slag, the mass ratio of mechanical-activated slag, desulfuized gypsum and carbide slag, sodium sulfate, and cement clinker was set as 85:10:3:2 firstly, then classifying the ratio of desulfurized gypsum in main activating agent (desulfurized gypsum+carbide slag) into 0%, 20%, 50%, 80%, 100%. As shown in Fig. 2, when the ratio of the desulfurized gypsum in the main activating agent is 50%, that is, the quantity of the desulfurized gypsum and the carbide slag is the same, the strength of the backfill material reaches the highest point, and the compression strength of 7d and 28d is 2.2 MPa and 3.3 MPa respectively.

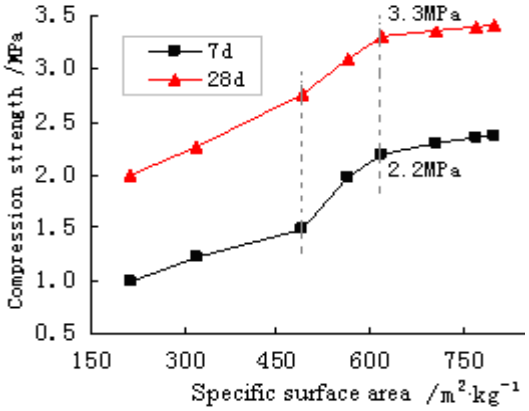

Fig. 1 Effect of specific surface area on compression strength of backfill materials

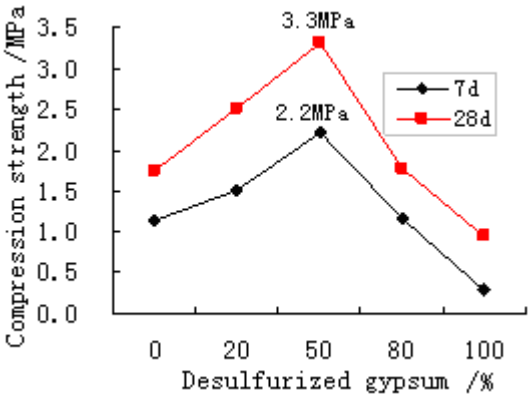

Fig.2 Effect of main activated agents on compression strength of backfill material

Effect of the supplementary activating agent on the strength of backfill material.

Based on abovementioned result that the best ratio of desulfuized gypsum and carbide slag is 1:1, further experiment was carried out to compare the effect of supplementary activating agent. Table 2 shows the proportions of the raw materials in each test scheme and the test result of the strength for each specimen is shown in Fig. 3, which shows that adding of Na_2SO_4 can apparently improve the strength of backfill material, and when the content of the slag is 81~85 wt%, the strength of the backfill materials reaches relatively higher point. From the viewpoint of making full use of water-granulated nickel slag, 85 wt% should be selected as the best proportion.

Table 2 Proportions of raw materials in each scheme [wt%]

Scheme No.	1	2	3	4	5	6	7	8	9
Mechanical-activated slag	85	81	77	73	69	81	77	73	69
Sodium sulfate	3	3	3	3	3				
Cement clinker	2	2	2	2	2	2	2	2	2
Desulfurized gypsum	5	7	9	11	13	7	9	11	13
Carbide slag	5	7	9	11	13	7	9	11	13

To examine the effect of cement clinker on the strength of backfill material, experiments were carried out that the proportions of the cement clinker in cementing raw materials was 2%, 3%, 4%, 5% and 6% respectively. The result shows that the compression and flexural strength of backfill material fluctuate with the increase of the dosage of cement clinker. In the aspect of saving cost by using less cement, the proper proportion of cement clinker in backfill material should be 2%.

Effect of slurry concentration on the strength of backfill material.

Based on the requirement that the flurry concentration of backfill material used in JGCL is 77%~79%, the mass ratio of mechanical-activated nickel slag, Na_2SO_4, cement clinker, desulfurized gypsum and carbide slag in cementing raw materials was set as 85:3:2:5:5, and backfill material with slurry concentration being 88%, 85%, 82%, 79%, 76% and 73% respectively were prepared. The test result of the strength of each backfill specimen is shown in Fig. 4.

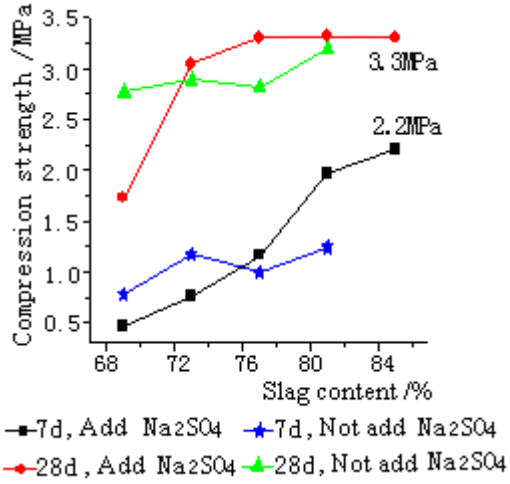

Fig.3 Effect of Na_2SO_4 on the strength of backfill material

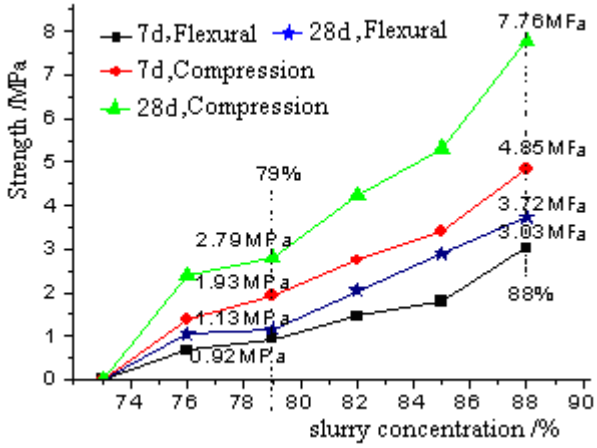

Fig.4 Effect of slurry concentration on strength of backfill material

It is shown in Fig. 4 that the strength of the backfill specimen increases with the growth of the slurry concentration, and when the slurry concentration reaches 79%, the highest point that was required, the flexural strength of the specimen cured for 7d and 28d reaches 0.92 MPa and 1.93 MPa respectively, and the compression strength reaches 1.13 MPa and 2.79 MPa respectively.

Effect of the fluidity of backfill material on its strength.

Backfill materials was prepared from raw materials whose mass ratio of the mechanical-activated nickel slag, Na_2SO_4, cement clinker, desulfurized gypsum and carbide slag was set as 85:3:2:5:5. The fluidity and strength were measured and then compared with the backfill material prepared by using Portland cement as cementitious material. Considering that water-reducing agent has an effect of improving slurry fluidity, a contrast experiment was carried out by adding high efficiency water-reducing agent which accounts for 0.156% of the total cementitious material. The comparison result is shown in Fig. 5.

Fig.5 shows that when the slurry concentration is 79~80%, the fluidity of the backfill material prepared by using mechanical-activated nickel slag is apparently higher than that of the backfill material using cement as cementitious agent. While the addition of high-efficiency water-reducing agent has greatly increased the fluidity of slag-based backfill materials, and the fluidity of slag-based backfill materials with slurry concentration of 82% is similar to that of the cement-based backfill materials. This method not only improves fluidity of the slurry, but also helps to improve the strength of the backfill material. The test results of strength show that among three backfill materials with same fluidity (390mm), the strength of the cement-based backfill material is the highest, the slag-based backfill material

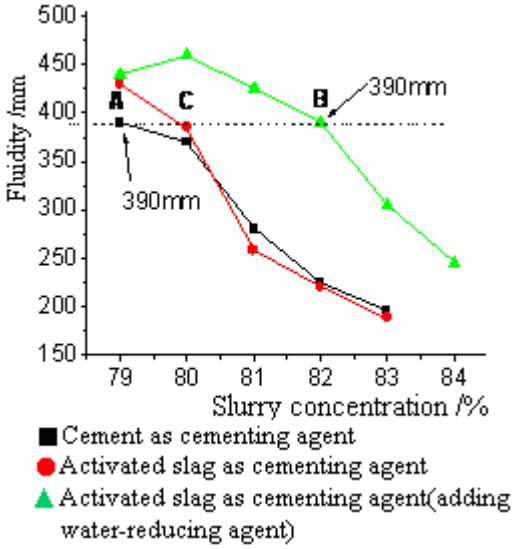

Fig. 5 Relation between slurry concentration and fluidity

with addition of high efficiency water-reducing agent takes the second place, and the strength of slag-based backfill material is the lowest. Although the strength of the slag-based backfill material prepared by adding high efficiency water-reducing agent is lower than that of the cement-based backfill material, its compression strength cured for 7d and 28d has reaches 3.93 MPa and 7.94 MPa respectively, which already meets the requirement of backfill operation [11].

Hydration products and hydration mechanism.

Fig. 6 is the SEM images of the slag-based backfill material that was hydrated for 28d. It can be seen that lots of floccular hydrated products have generated on and around the calcium-magnesium olivine crystals. In the hydration process, these substances lapped and adhered with each other to form irregular cementitious structure. The EDS spectrum of the B section in Fig.6b shows that the cementitious material consists of $CaO{\cdot}MgO{\cdot}SiO_2$ and little amount of Al_2O_3 and Na_2O, etc. These calcium silicates (aluminates) or magnesium silicates (aluminates) are the hydrated product of the water-granulated nickel slag under the action of activators.

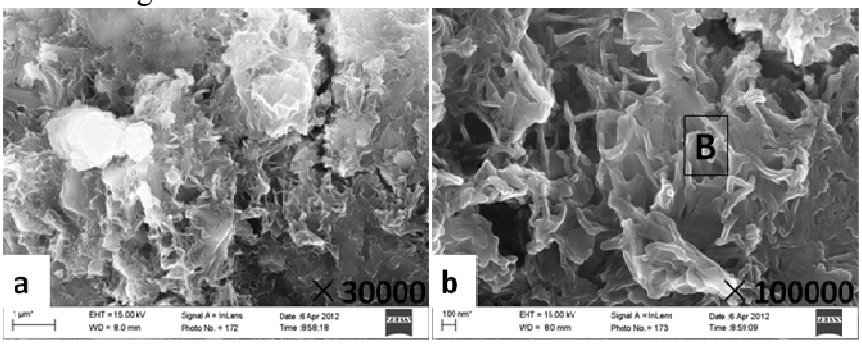

Fig.6 SEM images of water-granulated slag cementitious material hydrated for 28d

At the early stage of hydration, the C_3A and C_4AF from cement clinker reacted with gypsum ($CaSO_4{\cdot}2H_2O$) to form ettringite (AFt) and $Ca(OH)_2$. Due to the small amount of cement clinker, only little amount of AFt was produced in the reaction. Together with activating agents such as carbide slag, Na_2SO_4, and desulfurized gypsum, the $Ca(OH)_2$ produced in the reaction would have further reaction with the water-granulated nickel slag.

Carbide slag provided sufficient $Ca(OH)_2$ at the early stage of the hydrated reaction, which guaranteed the high concentration of OH^- in the system. The addition of sodium sulfate greatly affected dissolution of carbide slag, which was exhibited by the formation of gypsum after the reaction of sodium sulfate with calcium ion from carbide slag. Thus, the carbide slag was dissolved and the OH^- concentration in the system increased quickly, and as a result, silicate or aluminosilicate glass was dissolved steadily under the erosion of OH^-. Firstly, due to the absorption of OH^- by the Ca^{2+} and Mg^{2+} distributing on the surface of the silicate glass, some hydroxides formed and the surface structure of water-granulated nickel slag was destroyed. Secondly, because the chemical bonds such as Ca-O, Mg-O in the glass network were much weaker than that of Si-O, Al-O, the OH^- could have replacement reaction with Ca^{2+} and Mg^{2+}, which would destroy the network structure of the glass dominated by oxygen-silicon tetrahedron and oxygen-aluminum tetrahedron. Finally, with continuous depolymerization of the glass structure, complex reaction between various kinds of ions took place and the hydrated products formed. These products gradually nucleated, grew up, and eventually lapped with each other to form irregular network. In addition, under the erosion of OH^-, the Si-O-Al and Al-O-Al in the glass structure would gradually release Al ions, which would react with Ca^{2+} and SO_4^{2-} ions coming from sulfate activators to form ettringite ($3CaO{\cdot}Al_2O_3{\cdot}3CaSO_4{\cdot}32H_2O$). In the forming process of ettringite, the irons such as Na, Mg, Si would also participate in the reaction and form quasi-ettringite phase. Due to the participation of large amount of Mg in the reaction system, the final structure of hydrated calcium silicate would have large amount of Mg ions. Since the radius of the Mg ion is nearly equal to that of Ca ion, it is believed that the cementing performance of this kind of hydrated product is similar to that of hydrated calcium silicate, which would mainly affect the later strength of the slag-based cementitious material.

Conclusions

Mechanical activation result shows that the best specific surface area of the water-granulated nickel slag should be 620 $m^2 \cdot kg^{-1}$, and the effect of excessive grinding is not so distinctively. Activators such as desulfurized gypsum, carbide slag, sodium sulfate and cement clinker help to activate the activity of the water-granulated nickel slag. Under the condition that the dosage of nickel slag accounts for 85% in the cementitious material, the best mass ratio of these activators is 5%, 5%, 3% and 2% respectively. Adding of PC high efficiency water-reducing agent which accounts for 0.156% of the total cementitious material helps to improve performance of backfill slurry. Backfill material prepared by using activated-slag as cementitious material can meet not only the fluidity requirement under special slurry concentration, but also the strength indexes required by JGCL.

Keywords: polypropylene; melt-blown nonwoven fabric; plasma; hydrophilicity

Abstract: The melt-blown polypropylene nonwoven fabric plasma treated to graft with acrylic acid has been investigated by FTIR, SEM and Contact Angle Determinator respectively. It was found that after grafting with acrylic acid the wettability of the PP nonwoven fabric could be significantly improved from 140.9°to almost 0°in a short period of time by plasma treatment and increased to 110.6° and 133.2° after 20 days and 40 days respectively. However, the wettability of acrylic acid grafted PP nonwoven fabric could be improved to 72.9°with a permanent hydrophilic behavior.

Introduction

Recently, polypropylene fiber has drawn great attention from the scientific research and industry for its light, high strength, good flexibility, corrosion resistance, good filtering performance, low cost, and has become one of the most developing products in the field of non-woven fabric[1,2]. Polypropylene fiber has not only certain characteristics of high crystallization rate, none-hydrophilic group, but also the shape of circular, dense structure, lacking of microporous and crannies, which limit the scope of application of the polypropylene fibers. Since the hydrophilicity of untreated melt-blown PP nonwoven fabric is poor and difficult to be infiltrated by an aqueous solution, the effective area of the filter material is reduced, which results in slowing filtration rate, extending the filtration time and reducing the efficiency[3]. Therefore, the surface modification, for example, the introduction of a hydrophilic group, etc., is a effective way to permanently alter the wetting properties of the fibers[4]. In different surface modification techniques, plasma treatment is considered the most effective method[5-7]. In this article, the surface of PP nonwoven fabric was grafted with acrylic acid using the method of He plasma to change its surface properties. The surface structure, morphology and surface properties of the PP nonwoven fabric before and after grafting were investigated systematically.

Experimental

Materials and Equipments

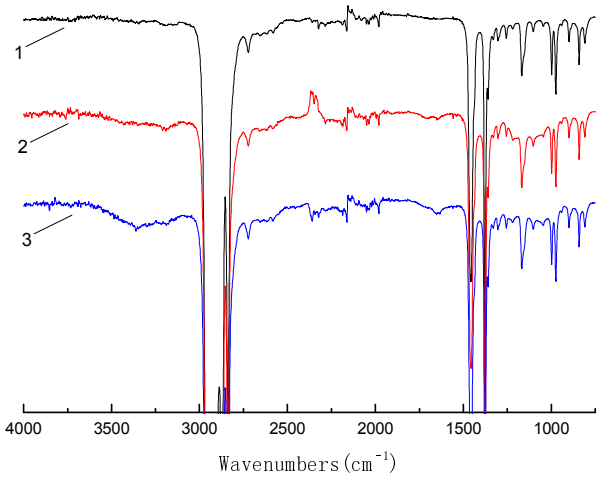
The raw material is melt-blown PP nonwoven fabric with a planar density of 45-55g/m^2 (laboratory preparation). The chemical reagent is acrylic acid (type Q/CYD2848-2007) from Sinopharm Chemical Reagent Co., Ltd. The equipments are the Cold plasma modification treatment Instrument(SY-I type 500W RF power source from ChangZhou ZhongKe ChangTai Plasma Technology Co., Ltd), Contact angle determinator(type OCA40Micro from German Dataphysics Co.), Scanning electron microscopy(type JSM-5600LV from Japan JEOL Co.), Fourier transform infrared-Raman spectrometer(type Nicolet Nexus 670+Raman Module from USA Thermo Fisher Co.).

Plasma Treating

The PP nonwoven fabric was grafted with acrylic acid in a method of atmospheric liquid phase in this article. Before starting the plasma treating, the PP nonwoven fabric was firstly cleaned with distilled water, placed in 70% ethanol for 24 hours, then cleaned with distilled water three times and dried for back up. After that, the PP nonwoven fabric was cut into 4×7(cm) rectangular cloth strips to hang in the cold plasma processing instrument, and then maintained the chamber pressure at about 20Pa with the high frequency power of 100w to supply the plasma treatment for 8min. The treated samples were left to stand in air for 30min, so that the free radical on the PP nonwoven fabric surface was reacted with oxygen, converted to a relatively stable peroxide group.

Graft Polymerization

The activated PP nonwoven fabric was immersed in 40% concentration of the acrylic acid monomer solution, heated to the 50℃ using water bath for 6 hours. Grafted PP nonwoven fabric was ultrasonic cleaned several times with distilled water, and then washed in 60℃ distilled water for 6 hours. The purified samples were natural dried in room temperature and stored for further analysis.



Characterization

The PP nonwoven fabric was cut into 1×5(cm) and fixed on the German Dataphysics company OCA40Micro video contact angle tester. Each sample was measured 15 points derived by software, the average value of them was the contact angle of the samples. The PP nonwoven fabric surface was observed by scanning electron microscopy. The study of the molecular structure and chemical bonding change of the PP nonwoven fabric before and after the plasma treatment can be characted by Fourier transform infrared spectroscopy with the ATR analysis within scanning range of 4000-400cm^{-1} .

Results and Discussions

Ftir Analysis of the PP Nonwoven Fabric

The surface structure of PP nonwoven fabric was observed by infrared spectroscopy before and after plasma treatment, as shown in Fig. 3. The C=O characteristic absorption peak was located at 1750cm^{-1} in curve 2 for plasma treated PP nonwoven fabric. There was also a wide absorption band in 3500~3000 cm^{-1} region corresponding to the -OH stretching vibration peak, because the active groups reacted with the oxygen in the air to form groups such as -OH, C=O. In curve 3, it appeared a characteristic absorption peak of the ester bond at 1800~1600 cm^{-1} and a wide absorption peak in the region of 3500~3000 cm^{-1} corresponding to the -OH stretching vibration. However, the untreated PP non-woven fabric on the infrared spectra did not show any above absorption peak in curve 1. The experimental results show that the PP nonwoven fabric has been successfully grafted with acrylic acid.

Sem Analysis of the PP Nonwoven Fabric

The surface morphology of the PP nonwoven fabric was shown in Fig. 2. Before helium plasma treatment, the original sample of the PP nonwoven fabric was smooth, as presented in Fig. 2 (a) and (b). However, after helium plasma activation etching, the surface of the PP nonwoven fabric fibers was etched and cracked, and as shown in Fig.2 (c) , this is formed because the surface effect by the physical and chemical reactions. The etching of the fiber surface played a positive role in improving the hydrophilicity of the PP nonwoven fabric. The surface morphology of the PP nonwoven fabric grafted acrylic acid was shown in Fig.2 (d). It was no longer smooth and just liked coating with a layer covering. The mutual adhesion between the fibers appearing the "bridging" phenomenon indicated that the PP nonwoven fabric surface was successfully grafted acrylic.

a. The Original Sample (X500) b. The Original Sample (X5000)

c. The Plasma Treated Sample (X5000) d. The Grafted Sample (X2000)

Fig. 2 The Sem Image of The PP Nonwoven Fabric

Changes of the PP Nonwoven Fabric Hydrophilicity

The surface contact angles of PP nonwoven fabric before and after modification were shown in Fig. 1.The surface contact angle of the untreated sample was 140.9° (Fig.1(a)), plasma treated sample was almost 0° (Fig. 1(b)) , and acrylic acid grafted sample was 72.9° (Fig.1(c)). After plasma treatment, PP nonwoven fabric surface was rich in a number of reactive groups, so that the surface contact angle changed to almost 0° . In the grafting process, the activated surface of the PP nonwoven fabric had only a small amount of effective group grafting with acrylic monomer and most of the groups were disappeared. Thereby, the contact angle of the grafting sample was larger than the one only plasma treated sample.

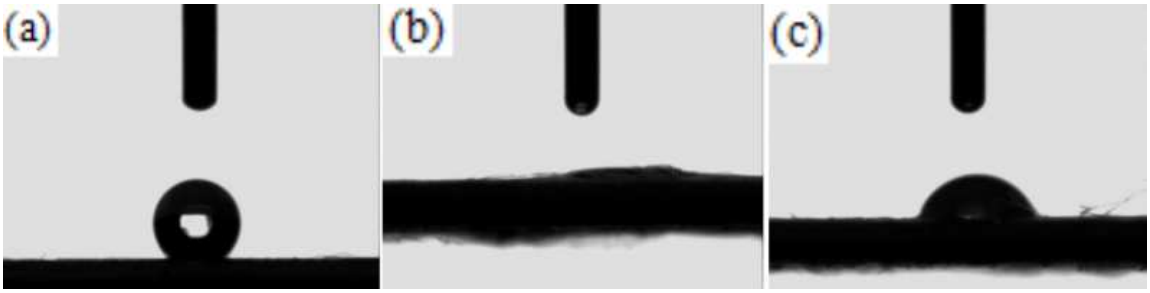

Fig. 3 The Surface Contact Angles of PP Nonwoven Fabric Before And After Modification

(a) Untreated; (b) Plasma Treated; (c) Acrylic Acid Grafted

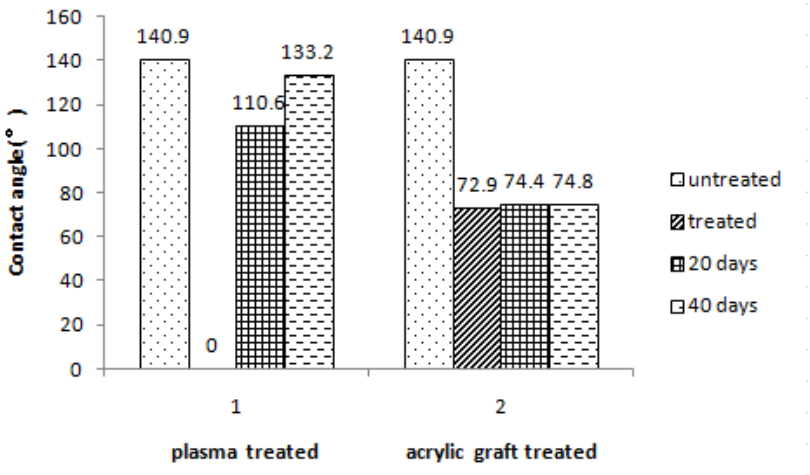

Fig. 4 The Changes Of Contact Angles Before And After Modification

Although the plasma treatment can increase material hydrophilicity, but after a period of time, the hydrophilicity of PP nonwoven fabric will deteriorate, as shown in Fig. 4. After the plasma treatment, PP non-woven fabric reduced the contact angle to 0°, it increased to 110.6° and 133.2° after 20 days and 40 days respectively. But the hydrophilicity of acrylic acid grafted PP nonwoven fabric was stable and non-aging. This is because the volume of the molecular chains of polyacrylic acid is much greater than the one introducing polar groups by the plasma treatment on the surface. They are difficult to flip and migrate in the PP nonwoven fabric but reside on the nonwoven fabric surface stably to achieve a permanent hydrophilic.

Conclusion

(1) After plasma treatment modification, the surface structure of PP nonwoven fabric has been changed and the surface morphology of the PP nonwoven fabric appeared the "bridging" phenomenon. The results indicated that the PP nonwoven fabric surface was successfully grafted with acrylic.

(2) The surface contact angles of PP nonwoven fabric were significantly improved from 140.9°to almost 0°in a short period of time after plasma treatment and the grafting sample was larger than the one only plasma treated sample. However, the hydrophilicity of grafted PP nonwoven fabric was stable and the contact angle of the surface did not change with time.

Keyword: Multiple principal elements, High entropy alloy, Microstructure, Mechanical properties

Abstract: Five common elements Co, Cr, Fe, Ni and Al were selected, and CoCrFeNiAl was prepared by arc-melting. The microstructure and mechanical properties after spot welding were studied. The results show that the cast microstructure of high entropy alloy CoCrFeNiAl is relatively uniform with a dendritic morphology. The heat is inversely proportional with the alloy grain sizes. The greater the heat is, the smaller the grain size is, which leads to the higher hardness and more uniform tissue. But there is a critical value of the heat(H_{crit}) in spot welding. When H_{actu}(actual heat) exceeds H_{crit}, it will adversely affect the performance, resulting in crack, splash and other defects.

Introduction

For thousands of years the development of practical alloy systems has been based mainly on one principal element as the matrix, as in iron-based, copper-based, and aluminum-based alloys, limiting the number of applicable alloy systems, even though a substantial amount of other elements is incorporated for property/processing enhancement [1,2]. Since the 1970s, metal-matrix composites and intermetallic compounds have attracted much attention [3-4]. During this time, new processing technologies such as rapid solidification and mechanical alloying have become popular [5-7]. In 1995, Taiwan scholar Ye Wei, etc. [8] were the first to break the traditional concept of the material design, a new alloy design concept, namely high entropy alloys. Due to the high entropy alloy has many traditional alloys do not have the excellent characteristics, such as through appropriate alloy formulation design, availability of high hardness, high work hardening, softening temperature, high temperature oxidation resistance, corrosion resistance and other characteristics of high portfolio therefore have great potential[9-12].

Spot welding is the method of assembled the welded into the lap joints, pressed between the two electrodes, using the thermal of resistance melt base metal, forming solder joints. With high structural strength, joint good sealing, saving material, reduce the structural weight, production efficiency, therefore, the applications of spot welding in the material increasingly have been important. Previous studies were based on microstructure, mechanical properties of six element or more main element of high entropy alloys, while the research of five element of high entropy alloy welding properties was few, so in this article through the spot welding two identical high-entropy alloys, the spot welding heat was changed to study the microstructure and mechanical properties.

Experimental

Alloys with high purity Al, Co, Cr, Fe, Ni were taken as a raw material in an argon atmosphere. The vacuum arc was employed to melting alloy. The alloy was cut into 9 equal parts, each spot welding 2 equal parts, the remaining parts of a 1 reference, each specification is 30mm × 5mm × 1.5mm, spot welding parameters are shown in table 1. Optional DN-16 type spot welder for spot

welding, spot welds by grinding, polishing, etching, the morphology was observed under the microscope, and then microhardness was measured by the A-200-type hardness meter GALILEO , with applied load of 300N.

TABLE 1 WELDING PARAMETERS

Sample	heat	pressing time(s)	power on time(s)	cooling time(s)	maintenance time(s)	off time(s)

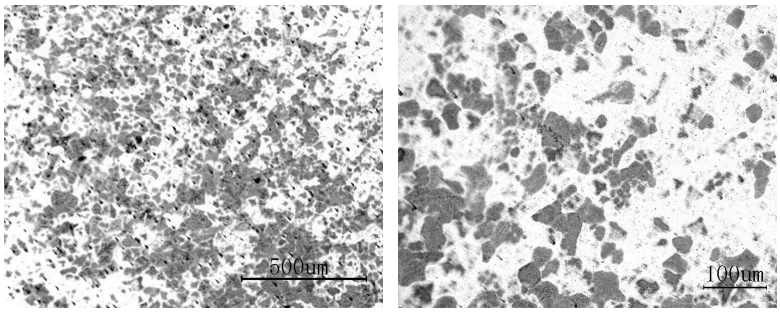
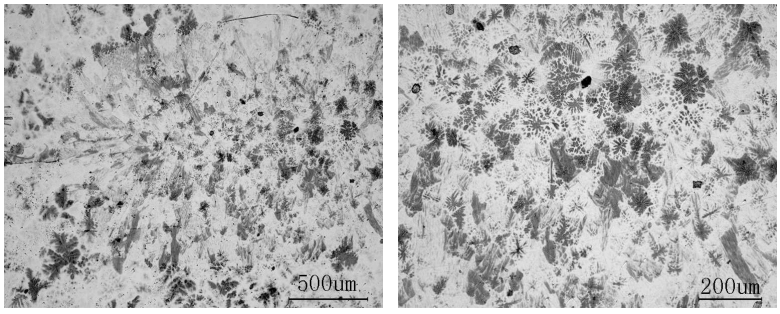
5	0.153Q	1	0.6	0.4	0.4	1

Results

Microstructure

Fig.1 is the microstructure photograph of sample 1 (unwelded). It can be seen that alloys original tissue is uniform, a single structure, and a typical dendritic phase can be observed.





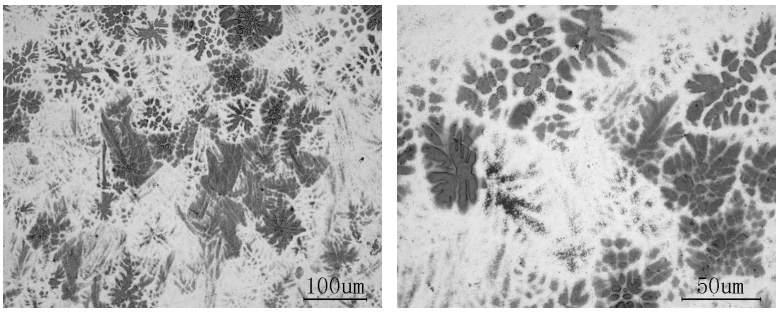


Fig.1 Microstructure of Sample 1

Fig.2, Fig.3 and Fig.4 are the photomicrograph of the sample 2, 3 and 4 after welding, respectively. Fig.2(a) and Fig.3(a) indicate the tissue of weld and fusion zone. (b), (c) and (d) represent the fusion zone tissue. The fusion zone grain size is less than elsewhere, from the Fig.(a), respectively. It can be seen that welding can refine the grains, enabling organizations to be more uniform, and has a certain size circular heat-affected zone, so the heat is the heir round outward diffusion of heat.

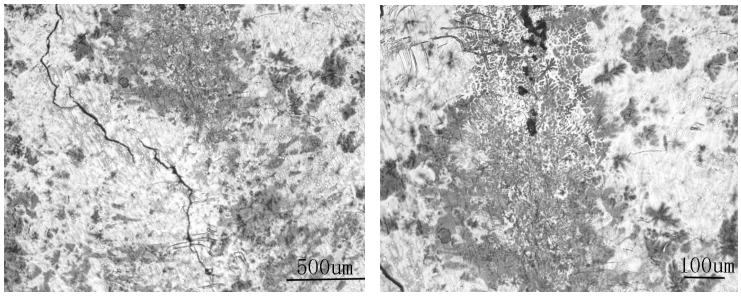
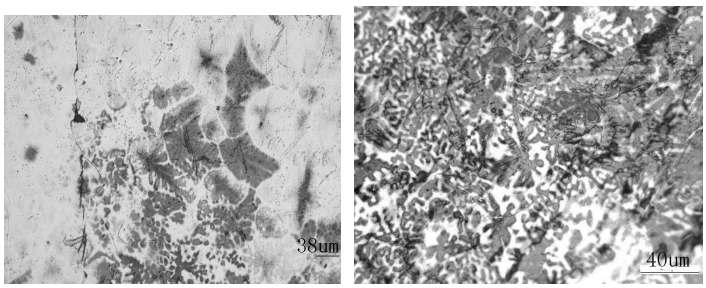
(c) 200X (d) 500X

Fig.2 Photomicrograph of Sample 2 after Welding

The alloy cracks in the nugget from Fig.4 (a). The deformations of welded joints under the action of thermal result in non-uniform stress and strain fields are uneven. In the welding process, the welding heat is too large, resulting in metal melting and excessive expansion. Nugget will be under pressure, in the influence of low temperature base material near the electrode and the molten metal b and d shows an image fusion zone, c shows the grain around the weld. It can be seen dendritic grain in all figures, and grain size of the fusion zone is much smaller than elsewhere, which can be drawn, welded produce a certain size heat-affected zone, the closer the weld, the greater the intensity and the smaller size of grains.



(a) 50X (b) 100X



(c) 200X (d) 500X

Fig.3 Photomicrograph of Sample 3 after welding

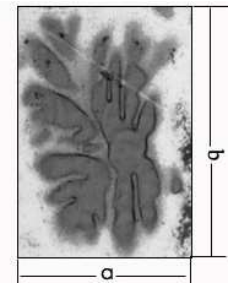
Fig.4 Photomicrograph of Sample 4 after Welding

Fig.5 is the image of sample 5 after welding. The welding heat is too high, causing splashing, which illustrates there is a critical value of the heat(H_{crit}) in spot welding. When H_{actu}(actual heat) exceeds H_{crit}, it will adversely affect the performance.

Fig.5 Sample 5 after Welding

Dendritic grain size is shown in Fig.6. a and b are the grain size of horizontal and vertical, respectively. Four samples grain size were measured and draw the diagram of grain size versus heat, as shown in Fig.7(a) and Fig7(b). That is to say, the grain size reduces with the increase of heat.



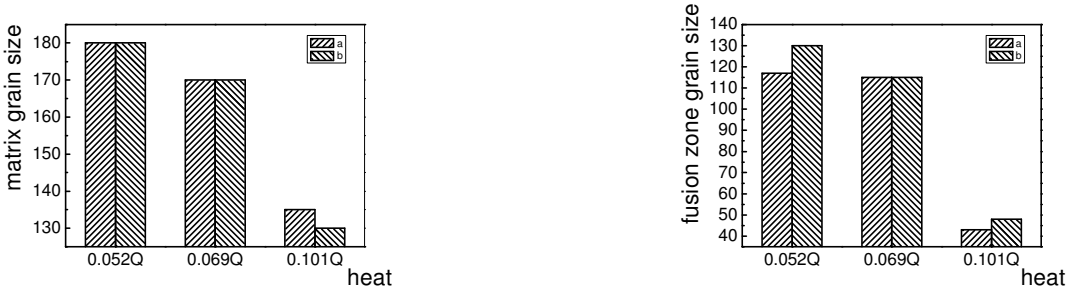


Fig.6 Grain size

(a) matrix grain size versus heat (b) fusion zone grain size versus heat

Fig.7 Grain Size Versus Heat

Mechanical Properties

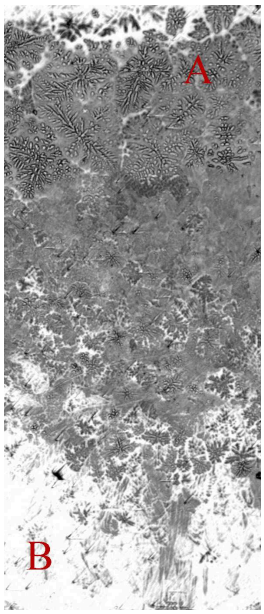

Fig.8 Photomicrograph of Sample after welding

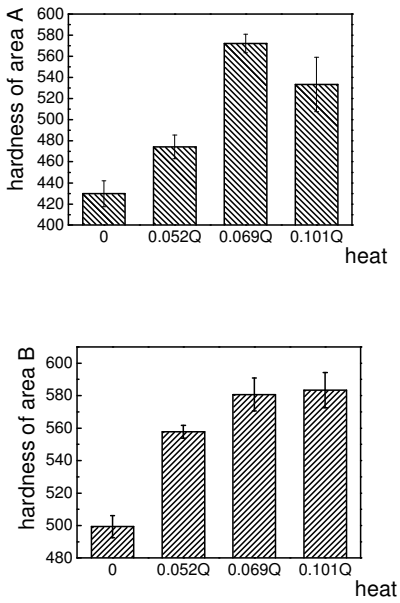

Fig.9 Hardness versus heat

As is show in the Fig.8, A is a branched grain of gray body region, and B is the matrix white region. A and B regions between the hardness of the heat are shown in fig9. Alloy weld zone hardness and heat relationship was shown in Fig.10. The hardness is inversely proportional with the heat.

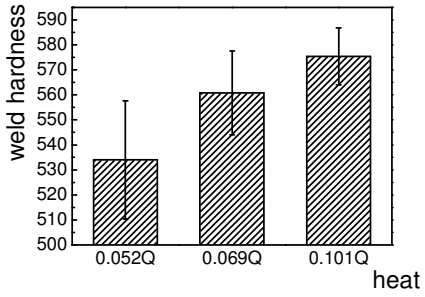

Fig.10 Weld Hardness Versus Heat

Spot welding is a typical transient heat transfer with internal heat source problems, dominated by thermal conduction when weldments obtained thermal. Transient nonlinear heat conduction equation is:

$$cp\frac{\partial T}{\partial t}=\frac{\partial}{\partial x}\left(k_x\frac{\partial T}{\partial x}\right)+\frac{\partial}{\partial y}\left(k_y\frac{\partial T}{\partial y}\right)+\frac{\partial}{\partial z}\left(k_z\frac{\partial T}{\partial z}\right)+Q$$

c --specific heat capacity of the material(J/Kg·K);
p--density;
T --temperature field distribution function;
t--time;
k_x, k_y, k_z--thermal conductivity of x, y, z,in this experiment k_z is 0;
Q--internal heat source

Cooling rate V($\frac{\partial T}{\partial t}$) is as Q increases by the formula, the cooling rate is greater, the smaller the grain size,so the grain size is decreased with the increase of Q.

According to Hall Page formula：

$б_S=б_0+Kd^{-1/2}$

Where $б_s$ represents the yield strength;$б_0$ expressed intragranular resistance to deformation, the equivalent of a great single crystal yield strength; K reflects the impact of grain boundaries on the deformation coefficient is the average grain diameter. Conclusions it can be concluded that the smaller the grain size, the greater the yield strength, corresponding to the higher hardness of the alloy from the formula, and consistent with experimental data.

Conclusions

CoCrFeNiAl was prepared by arc-melting, the microstructure and mechanical properties after spot welding were studied. The results are as follows:

(1) The cast microstructure of high entropy alloy CoCrFeNiAl is relatively uniform，with a dendritic morphology.

(2) The hardness of the alloy is proportional with the welding heat, because the heat is inversely proportional with the alloy grain sizes, the greater the heat, the grain size is smaller, the higher the hardness and more uniform tissue.

(3) There is a critical value of the heat(H_{crit}) in spot welding. When H_{actu}(actual heat) exceeds H_{crit}, it will adversely affect the performance, resulting in crack, splash and other defects.

Microstructure Refinement and Crack Initiation in the Forging Process

Wenlong Zhao[1, a], Qingxian Ma[1, b]

[1]Department of Mechanical Engineering, Tsinghua University, Beijing, 100084, China

[a]zwl2007010475@163.com, [b]maqxdme@mail.tsinghua.edu.cn

Keywords: Heavy forging, Forging, Microstructure refinement, Crack.

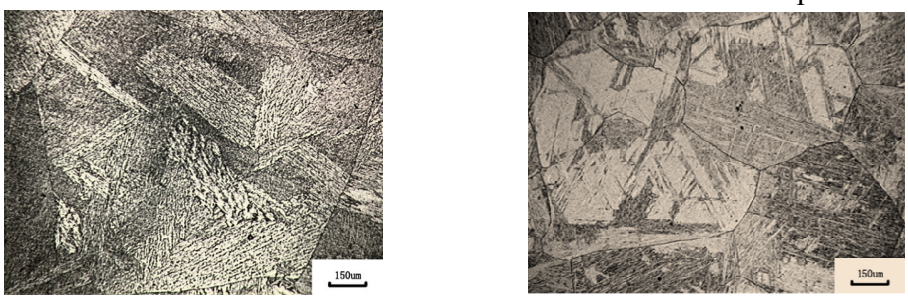
Abstract. In this paper, the type and morphology of defects in heavy ingots were detected mainly on the basis of experimental results, which were obtained by metallographic analysis of the materials dissected from one 380 ton 30Cr2Ni4MoV ingot. Then the evolution of typical defects in the forging process was investigated at temperatures ranging from 900˚C to 1200˚C and reduction ratios ranging from 0% to 50%. It was shown that coarse grains and inclusions were the main types of defects. In the forging process, the refinement of coarse grains and crack initiation at inclusions were summarized respectively with respect to temperature, reduction ratio and multi-pass forging. The microstructure evolution of 30Cr2Ni4MoV steel is accompanied by the formation of fine grains on condition that multi-pass forging or an optimal reduction ratio of 10% is adopted at temperatures lower than 1000˚C, while temperatures higher than 1100˚C can lead up to coarse grains. Besides, cracks originate from CaO and FeS inclusions at 900˚C and 1000˚C related to intense shear stress and melting of the FeS-Fe eutectics distributing along grain boundaries.

Introduction

In spite of the high strength and good ductility, 30Cr2Ni4MoV steel is widely used as the turbine rotor material in China due to its ductile-brittle transition temperature below the room temperature when compared with other structural steel [1,2]. However, as the volume and weight of a steel ingot increase gradually, more and more attention is turned to the elimination of casting defects existing in heavy ingots instead of the improvement of material itself in the technical field of heavy forgings. Although the quantity, distribution and size of casting defects are kept within a certain range by the advanced casting technology, they cannot be removed completely. Therefore, forging becomes the effective material processing method to control casting defects, such as coarse grain, non-metallic inclusion, segregation, shrinkage and loose et al. to meet the required standard, which ensures the service performance of a heavy forging not to be seriously affected [3,4].

In order to prevent casting defects from being the potential hazards affecting the mechanical properties of a heavy forging, details on the types and morphology of casting defects were discussed firstly in this paper by dissecting one 380 ton ingot. Then the evolution in the forging process of the typical defects was investigated by means of thermal experiment and numerical simulation conducted on the platform of Deform-3D. This research aimed at providing a theoretical framework for the microstructure control and property improvement of heavy forgings.

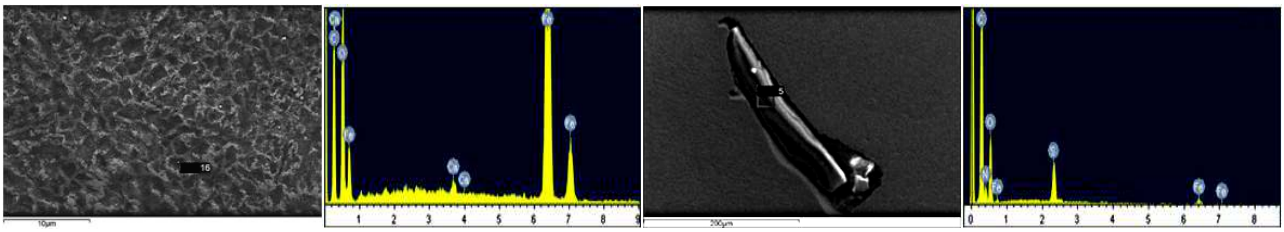
Experimental Material and Procedures



The material used in the experiment was 30Cr2Ni4MoV steel, which was dissected from the nozzle of one heavy ingot for a 1000MW low-pressure turbine rotor. The main chemical compositions and contents are (wt. %) C 0.280, Cr 1.720, Ni 3.630, Mo 0.410, V 0.110, Mn 0.020, Si 0.010, P 0.003, S 0.003 and Fe (balance).

To detect the defects of cast ingots, a large number of specimens along different orientations of the ingot were prepared after grinding and polishing, and then etched with the saturated picric acid solution for recording the optical micrographs. To explore the evolution of casting defects in the forging process, some cylindrical specimens were machined with a diameter of 30mm and a height of 45mm. Then the specimens were heated to 900˚C, 1000˚C, 1100˚C, 1200˚C and compressed at the reduction ratio of 0%, 10%, 20%, 30%, 40%, 50% respectively. After deformation, the specimens were quenched into cold water immediately to keep the austenite structure. Finally, all the specimens were sliced along the axial section and followed by grinding, polishing and etching.

The types and Morphology of Typical Casting Defects



Optical microscopic observations of the dissected specimens show that coarse grains and non-metallic inclusions are the typical defects in the 30Cr2Ni4MoV steel ingot. Coarse grains primarily consist of columnar and equiaxed grains, as shown in Fig. 1. Foreign inclusion CaO and endogenous inclusion FeS are the main types of non-metallic inclusions, as shown in Fig. 2.

The mechanical properties of heavy forgings can be seriously affected by coarse grains. In addition, the dendritic segregation which deteriorates the performance of steel usually appears in the columnar zone of a casting. Cracks originating from inclusions are one of the main causes of forging scrap. In case the forging conditions are not controlled properly, the size of coarse grains may be beyond the normal size and the non-metallic inclusions cannot be dispersed.

Refining Law of Coarse Grains

Effects of Temperature and Deformation on Grain Refinement

The average grain size in the primary deformation zone of the specimen was measured after deformation at different experimental conditions, and the grain size grade was also calculated (see Table 1).

After deformation, fine grains can be formed at 900˚C and 1000˚C, while the grain size increases obviously when the temperature is higher than 1000˚C. Fig. 3 illustrates that the lower the temperature, the finer the grains. The main reason for the tendency can be discovered from the grain

growth curve of 30Cr2Ni4MoV steel in Fig. 4 which demonstrates that grain coarsening occurs at about 950˚C, and after that the grain size rises from 40um to 180um rapidly. Therefore, in the forging process, the recrystallized grains will grow fast to a larger size corresponding to each temperature, especially for the grains formed at temperatures higher than 1000˚C.

The reduction ratio has a complex effect on the grain size due to the occurrence of dynamic recrystallization, grain growth and grain elongated with the deformation proceeding. However, a comprehensive analysis of the grain size at 900˚C, 1000˚C, 1100˚C and 1200˚C has found that there exists an optimal reduction ratio at which microstructure gets refined furthest and the grain size is more uniform than the as-cast. The optimal reduction ratio is 10%, independent of temperature.

Fig.5 Microstructure at 900˚C and the Total Reduction Ratio of 25%

Effect of Multi-pass Forging on Grain Refinement

The multi-pass forging has a significant impact on the microstructure refinement of 30Cr2Ni4MoV steel. Compared with one-pass forging at the reduction ratio of 25%, two-pass forging with each reduction ratio of 12.5% makes more contributions to the refinement of microstructure and uniformity of grain size. What is more, two-pass forging increases the area of the region where dynamic recrystallization occurs and the volume fraction of dynamic recrystallization at the same position of the ingot. After two-pass forging, the average grain size is refined to 6.50um, which ensures heavy forgings to have more excellent mechanical properties. Comparison of the two microstructure formed in one-pass and two-pass forging is shown in Fig. 5. Numerical simulation illustrating two-pass forging raise the volume fraction of dynamic recrystallization is shown in Fig. 6.

Fig.6 Distribution of Dynamic Recrystallization Volume Fraction in the Vertical Section

Crack Initiation in the Forging Process

Cracks Originating from CaO Inclusion

Three cracks originated in the outer wall of the specimen deformed at 900˚C, as shown in Fig. 7. The intermediate crack connects the upper and lower cracks, leading the three cracks to be joined with an axial angle of about 45°. The fracture is smooth, dark black and similar to the surface of the CaO inclusion shown in Fig.1 (a). CaO is brittle inclusion which has low intensity, poor plasticity and is easy to generate a concentration area of large strain and stress in the forging process.

Fig.8 indicates that a reduction ratio of 30% can make the intense shear strain generated in the axial section of the ingot and the angle between the large strain zone and the axis is about 45°. Due to its poor deformation capacity, the CaO inclusion separates from the metal matrix gradually with the deformation proceeding in virtue of shear stress generated in the upsetting process, so that micro cracks originate from the interface between the inclusion and the matrix. Meanwhile, low temperature such as 900˚C is not conducive to the diffusion of metal atoms. Therefore, micro cracks continue to expand and ultimately bigger faults are formed.

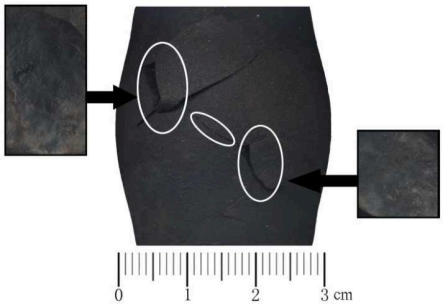

Fig. 7 Cracks after Deformation at 900˚C

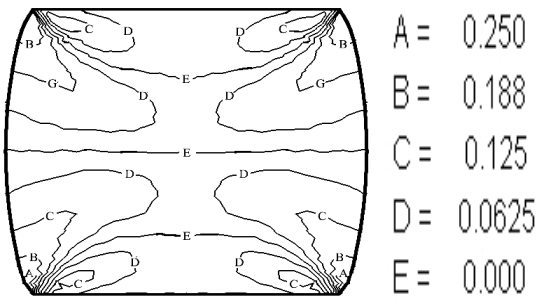

Fig. 8 Distribution of Shear Strain in the Vertical Section

Cracks Originating from FeS Inclusion

Cracks along the grain boundaries originated both in the outer wall of the specimen and inside the specimen deformed at 1000˚C. The fracture is characterized by a rough and torn texture containing many deep furrows, and the tip of the crack inside the specimen disperses into several micro cracks, as shown in Fig. 9.

FeS can initiate the formation of the eutectics distributing in the grain boundaries with Fe, and the melting point of this eutectic is only 985˚C. The eutectics can weaken the strength of grain boundaries due to melting at temperatures higher than 985˚C and cracking along grain boundaries follows. The optical microscopic illustration in Fig. 9 shows that the eutectics are located in many grain boundaries instead of one, so several cracks are formed along the grain boundaries. The role of deformation on the behavior of cracks distributing densely at inclusions can be grouped into two aspects: On the one hand, small deformation has limited influence on the behavior of cracks, e.g. the tips of cracks inside the specimen are just in the rigid region, existing separately. On the other hand, large deformation can make cracks extend into metal matrix and joined with each other, e.g. several cracks in the outer wall of the specimen are just in the concentration area of stress, joined to be a bigger fault. In addition, when the deformation is large enough, the hydrostatic stress along the outer wall of the ingot will turn into tensile stress, as shown in Fig. 10, which further increases the tendency of cracking.

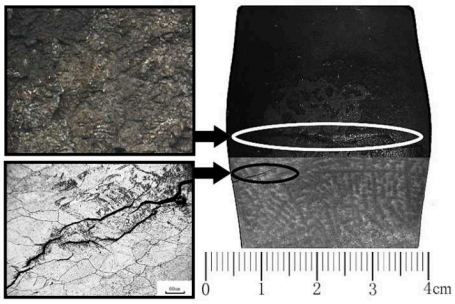

Fig. 9 Cracks after Deformation at 1000˚C

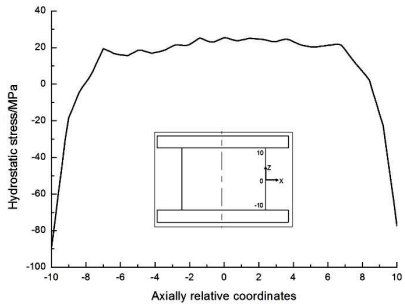

Fig. 10 Distribution of Hydrostatic Stress

Conclusions

Coarse grains and inclusions which are comprised of columnar grains, equiaxed grains, CaO and FeS inclusions are the typical defects of 30Cr2Ni4MoV steel ingot. It is shown that small deformation with temperatures below 1000˚C is conducive for fine grains to be formed. Additionally, multi-pass forging can reduce the grain size significantly at the same reduction ratio. Cracks originating from CaO and FeS inclusions are one of the main faults at low temperatures such as 900˚C and 1000˚C. CaO is brittle inclusion, and intense shear stress further leads up to such cracks. FeS-Fe eutectics enriched at the grain boundaries weaken the strength of grain boundaries due to melting at high temperatures, so FeS cracks originate easily affected by tensile stress.

Keywords：Fine grained 1420 Al-Li alloy, Superplastic forming, aging, strengthening mechanism

Abstract: Superplastic forming (SPF) is an important process for forming fine grained 1420 Al-Li alloy. However, the mechanical properties will be decreased after deforming at high temperature. How to obtain the optimize relationship of strength and ductility after SPF is one of the key problems for the process. In this paper, a set of artificial aging tests including single and two-step aging were carried out, which are the typical strengthening process for Al-Li alloy. Based on experimental results, strength and elongation were studied by means of tensile tests at room temperature, and the effect of aging processes on mechanical properties was analyzed. Finally, the microstructures fore and after aging were examined by OM and TEM, and the strengthening mechanism of 1420 Al-Li alloy was further studied. It is found that artificial aging especially two-step aging can increase mechanical properties of post-SPF material obviously, and δ'（Al_3Li）is the primary strengthening phase.

Introduction

Aluminum-lithium (Al-Li) alloys have been receiving a great deal of attention for application in aerospace industry because of their low density, high specific strength and stiffness, and good weldability. If Al-Li alloys are used in aircraft structures in place of convention aluminum alloys, the component quality can be reduced 10%~15% and the stiffness increased 15%~20%[1~3]. However, Al-Li alloys exhibit lower ductility and higher notch sensitivity at room temperature, which make the fabrication of useful thin-wall components difficult.

Superplastic forming (SPF) is a special processing, which is developed by superplastity of certain material under specific conditions of temperature and strain rate. It can form complex thin-wall components for Al-Li alloy. The advantages of the process include saving in machining and fastening time, and improved damage tolerance in the produced components[4][5]. The SPF also has several limitations; such as the material experiences long time at high temperature and the cavity formation will have a deleterious effect on any post-forming applications. For the aerospace industry, where it is desired to manufacture light weight stiff structures composed of few parts. Parts that are superplastically formed should be structurally stable in order to withstand the operational static and dynamic loading. Thus, post forming heat treatment, of the superplastically formed parts, is essential in enhancing their strength[6]. However, there are far fewer reports in the literature concerning precipitate control through different aging processes, especially by a two-step aging treatment on post forming 1420 Al–Mg–Li alloy.

Taking into account the aging strengthening of 1420 Al-Li alloy, the present work aims to investigate the effect of aging treatment on tensile performance and microstructure after SPF, and gain proper treatment process for increasing performance of formed parts.

Experimental procedure

The chemical composition of 8.5 mm thick 1420 Al-Li alloy hot rolled plate is listed in table 1. Thermomechanical processing(TMP) based on hot rolled plate is used in producing a fine grained structure, and the detail procedures of TMP are as following: solution-treated at 475℃ for 2h, quenched in water and then over-aging at 300℃/48h+400℃/4h. Subsequently preheated at 300~400℃for 1h, and then rolled to the final thickness of about 2mm, the rolling reduction per pass is 10%~20% and a rolling speed is about 0.427m/s. Finally, rapid recrystallization process is conducted at 510℃ for 30 min. The microstructure of the plates is shown in Fig 1 and the average grain size is about 12μm.

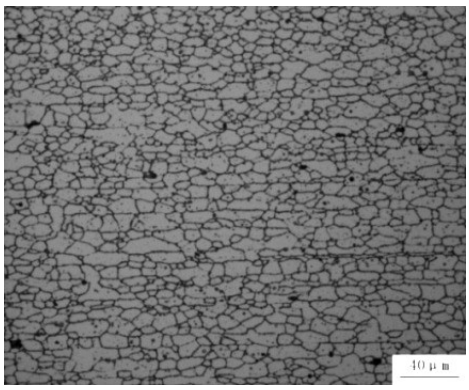

Fig.1 Microstructure of fine grained 1420 Al-Li alloy

Table 1 Chemical composition of 1420 Al-Li alloy (wt %)

Mg	Li	Zr	Ti	Cu	Fe	Si	Al
5.30	2.12	0.11	0.1	0.05	0.07	0.03	Bal

Rectangular pans with a dimension of approximately 250*250*40mm (Fig2) are fabricated on 150t SPF machine. Each is formed at 480 ℃, and the forming pressure is 0.8MPa with the rate of 0.02 MPa per miniute, and then keep pressure for 30 min. Tensile specimens are cut along the rolling direction from the bottom of rectangular pans, and then divided into five groups: (ⅰ) post-SPF without heat treatment; (ⅱ) aged at 170℃/12h; (ⅲ) solution-treated at 510℃ for 30min, quenched in water and then aged at 170℃/12h； (ⅳ) two-step aging at 120℃/4h+150℃/24h; (ⅴ) solution-treated at 510℃ for 30min, quenched in water and then aged at 120℃/4h+150℃/24h. Effects of heat treatment on mechanical properties and microstructure are studied by means of tension experiment and OM, TEM.

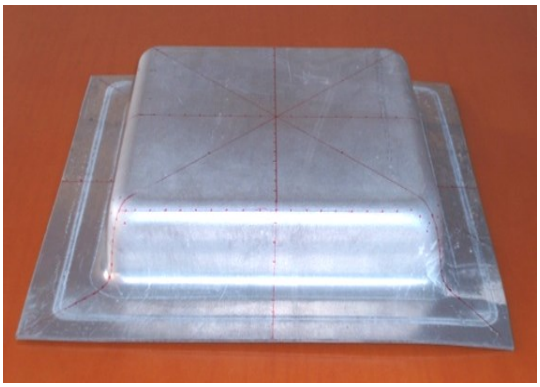

Fig.2 Rectangular pan of SPF

Results and Discussion

Microstructure and mechanical properties of post-SPF

Fig.3 shows the tensile properties of fine grained 1420 Al-Li alloy at room temperature before and after SPF. The results of the tensile tests indicate that there is a significant loss of tensile strength after SPF, ultimate strength is decreased 44.5% ,from 513MPa to 279.5MPa, and the yield strength is decreased 43%, from 323MPa to 184MPa.

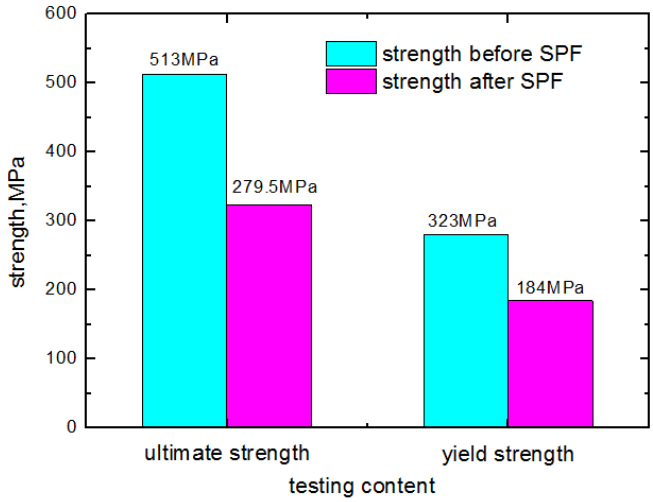

Fig.3 Tensile properties at room temperature of fine grained 1420 Al-Li alloy

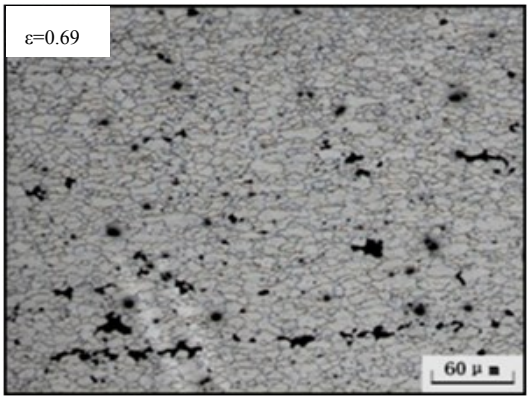
The microstructure of post-SPF which is obtained from the rectangular pan is shown in Fig.4. It is found that a large number of cavities are existed in post-SPF materials. Superplastic deformation is carried out at high temperature, and the evolution of microstructure plays very important role in the tensile properties of SPF materials. Dynamic grain growth and cavitation are the major result in the decreasing of mechanical properties for post-SPF materials [7-9].



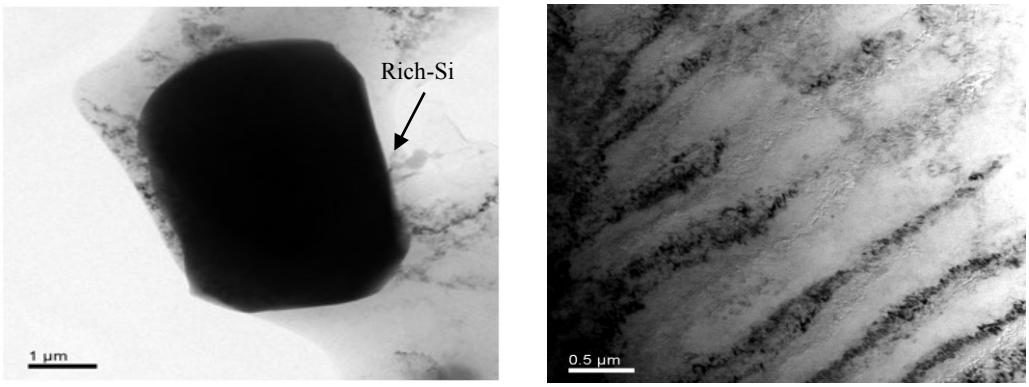


Fig.4 Microstructure of rectangular pan after SPF

Furthermore, the results of TEM are shown in Fig.5. Superplastic deformation temperature is usually higher than 0.5Tm (melting point) which is similar to solution treatment of Al-Li alloy. So most of second-phase particles are melted at that temperature, only rich-Si etal impurity particles (Fig.5(a)) are existed in the materials after SPF. In addition, materials experience to a certainty deformation, dislocation movement is an important deformation mechanism. There are a great deal of dislocations in post-SPF materials, as shown in (Fig.5 (b)).

（a）rich-Si particle (b) dislocation morphological

Fig.5 The results of TEM after SPF

The effect of artificial aging on tensile properties for post-SPF

The effect of several aging treatment systems on post-SPF tensile properties are shown in Fig 6. It is noted that aging treatment can improve the strength of post-SPF 1420 Al-Li alloy. For example, solution treatment at 510℃/ 30min and then aging at 170℃/12h, ultimate strength can be increased from 279.51MPa to 433.85MPa and the yield strength be increased from 184MPa to 238.7MPa. The ultimate and yield strength are individually increased 55% and 30%.

At the same condition, tensile strength with solution treatment are higher than the results without solution for post-SPF specimens. In comparison with single aging, it is discovered that the higher strength can be obtained after two-step aging. Such as the specimens are solution treatment at 510℃/30min, and then aging at 120℃/4h+ 150℃/24h, the ultimate and yield strength are separately reached to 482 MPa and 246MPa, which are similar to the materials before SPF.

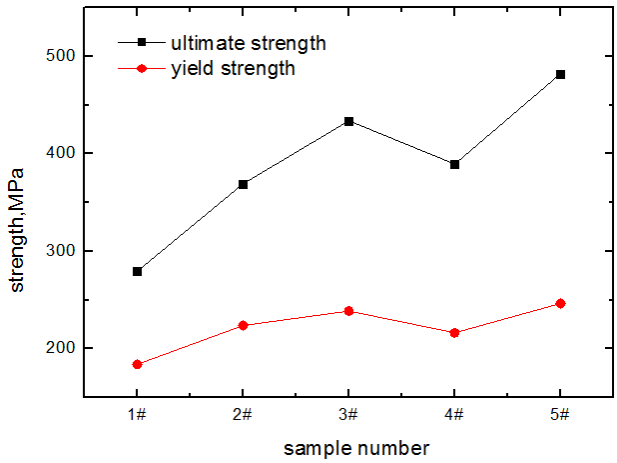

Fig.6 The effect of aging on tensile strength at room temperature after SPF

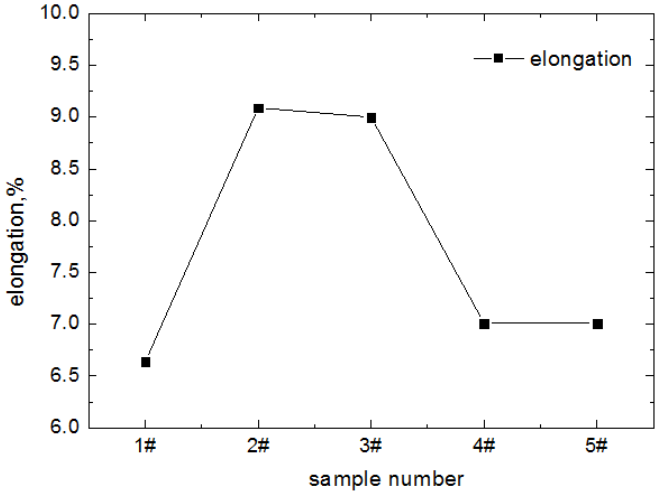
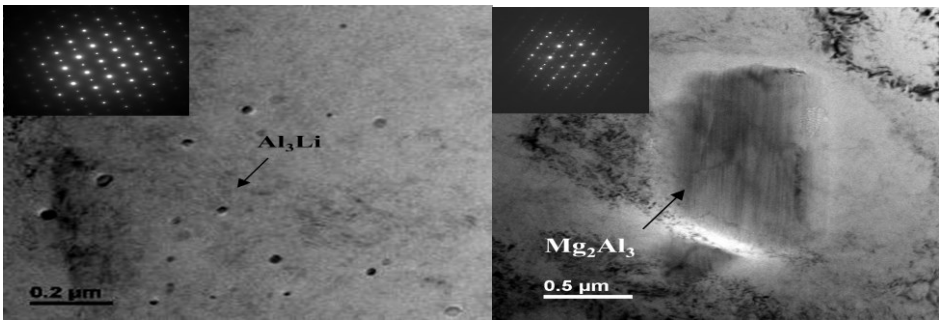
（1#：post-SPF without aging；2#：170℃/12h；3#：510℃/30min +170℃/12h；4#：120℃/4h+150℃/24h；5#：510℃/30min+120℃/4h + 150℃/24h）

Fig.7 shows the elongations at different aging parameters. Compared to post-SPF, all the elongations are increased after aging. For example, the elongation is increased from 6.64% to 9.09% after aging at 170℃/12h. The tensile strength is not only increased but also elongation is improved when artificial aging treatments are conducted after SPF.





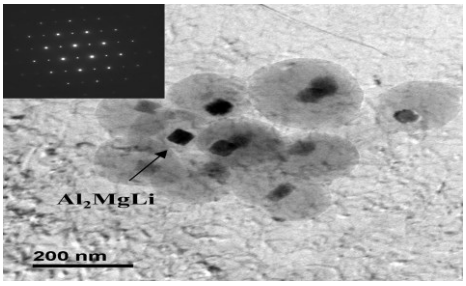


Fig.7 The effect of aging on tensile elongation at room temperature after SPF

The effect of aging on microstructure for post-SPF

Fine grained 1420 Al-Li alloy exhibits aging strengthening characteristic obviously, and which is owe to δ'（Al_3Li）precipitation and growth. To further investigate the strengthening mechanism of 1420 Al-Li alloy, precipitated phases are examined through TEM after aging at 510℃/30min+120℃/4h +150℃/24h, as shown in Fig.8. A large number of δ' phase (Fig.8(a)) which is the major strengthening phase are existed and distributed homogeneously in material after two-step aging. In addition, β（Mg_2Al_3）and S（Al_2MgLi）phases are precipitated, and S phase can improve coplanar slipping which is created by δ'. In consequence, stress concentration occurred in grain boundary will be weakening, and the strength and plasticity are increased after two-step aging for post-SPF products.

(a) δ'(Al_3Li) phase (b) β(Mg_2Al_3) phase

(c) S（Al_2MgLi）phase

Fig. 8 The precipited phases after two-step aging at 510℃/30min+120℃/4h +150℃/24h

Conclusion

According to the experiment on the artificial aging for post-SPF 1420 Al-Li alloy, the following conclusions can be obtained:

a) The mechanical properties of material are decreased obviously after superplastic deformation. Compared to the original plate without deformation, ultimate strength is decreased 44.5% from 513MPa to 279.5MPa, and the yield strength is decreased 43% from 323MPa to 184MPa.

b) Artificial aging can improve the strength of post-SPF. Compared to single aging, the strength is increased higher after two-step aging treatment, such as aging at 510℃/30min +120℃/4h +150℃/24h, the ultimate and yield strength are separately reached to 482 MPa and 246MPa, which are similar to the materials before SPF.

c) δ'(Al_3Li) phase is the major strengthening phase for 1420 Al-Li alloy. A large number of δ' phase are precipitated and distributed homogeneously in material after two-step aging for post-SPF. β（Mg_2Al_3）and S（Al_2MgLi）phases are also exsited, and S phase can improve coplanar slipping which is created by δ'.

Numerical Simulation of One Pulse Power Laser shock Peening

Lei Chen [1, a]

[1]Institute of Mechanical Engineering, Hangzhou Dianzi University, 310018, China

[a] ujs_cl@qq.com

Keywords: Laser shock peening, Shock wave, Residual stress, FEM

Abstract. Laser shock peening (LSP) is a novel technology of surface treatment. LSP utilizes a short laser pulse with high energy density, which induced a high pressure stress wave propagation and residual compressive stress on material surface. The effects of LSP of SAE9310 steel with a laser pulse of 14.2J at 2.9mm square beam have been studied by finite element method. The underlying formulation is based on Lagangian elastoplastic materials model. The propagation of shock wave, residual stress and plastic strain are simulated. The simulations show that the residual stress is mainly in the radial direction of the workpiece, and nearly zero in the longitudinal direction. The plastic strain remains on the processed surface dominantly. Divergences between theoretical and experimental residual stress occur due to the simplification of shock peening conditions.

Introduction

Laser shock peening (LSP), as shown in Fig.1, is a promising surface treatment technique similar to shock peening and has been shown to be effective in improving the fatigue properties of a number of metals and alloys by imparting compressive residual stresses in materials. LSP utilizes a high-energy, pulsed laser to vaporize an opaque overlay (i.e. black paint) applied to the surface of the sample. The ensuing vapor created by the ablation process is trapped between the sample and a transparent overlay (i.e. water), generating an extremely high localized pressure pulse of short time duration (~10 ns) which in turn causes a shock wave to propagate into material. Since the amplitude of this pressure pulse is much greater than the dynamic yield strength of the material, yielding occurs and the material is plastically deformed. The process was originally developed at the Battelle Columbus Laboratory in the 1970s [1]. Since then considerable attention has been paid to potential application of LSP in the aerospace and automotive industries. The beneficial effects of LSP on static, cyclic, fretting fatigue and stress corrosion performance of aluminum alloys, steels and nickel-based alloys have been demonstrated [2-5]. Laser shock waves are much more preferable than other sources (explosion, electron and ion accelerators) since they provide better experimental opportunities, allow more flexible control of their parameters, and have a more significant effect upon materials. Thus far investigation of laser shock waves, taking into consideration their similarity with other types of actions, allows the technological scope of application to be extended.

Much experimental work has been done to analyze LSP [6], but relatively little effort has been spent in studying the shock wave of LSP with analytical methods. Arif [7] used a finite difference algorithm to simulate propagation of stress wave in the material, and a finite element model to predict deformation and stresses. William [8] used a commercial software Abaqus/Explicit to analyze the one-sided and double-sided LSP.

Fig.2 shows the typical optical graph of dented region produced by LSP. The clearance d between two dented regions, as shown in Fig.2, is very important to the efficiency of the LSP. The objective of this work was to examine the effect region of laser shock peening on the workpiece. The residual stress acquired from simulation was compared with experiment.

FE Model

An elastoplastic FEM was used to simulate the one-sided LSP of a semi-infinite solid. The analysis was conducted by using MSC.Marc based on the Updated Lagrangian formulation. The pressure

pulse with duration of 40ns is modeled as a triangular ramp pressure [8], as shown in Fig.3. The pressure rises linearly to the max plasma pressure in a span of 10ns, and then decays linearly during the following 30ns. The max plasma pressure is given by:

$$P(GPa) = 0.01\sqrt{\frac{\alpha}{2\alpha+3}}\sqrt{Z(g\cdot cm^{-2}\cdot s^{-1})\cdot I_0(GW/cm^2)} \quad (1)$$

Where α represents the ionization energy of the plasma. $\alpha=1$ for a perfect gas. Here α was estimated to be 0.2 . Z is a reduced acoustic impedance ($2/Z=1/Z_1+1/Z_2$) of the confining (Z_1) and the target (Z_2) materials. I_0 is the laser intensity.

The material used in this study was SAE9310 alloy with chemical composition as listed in Table 1. Young's modulus and yield strength for SAE9310 were determined to be $2.16\times10^5\,MPa$ and $570MPa$, respectively. Poisson's ratio was assumed to be 0.28. The test sample is a cylinder with a height of 12mm and a diameter of 95mm. The geometries of the specimens are shown in Fig.1. The laser beam spot size was maintained at $2.9mm\times2.9mm$. The Laser power density used was $5GW/cm^2$. The residual stress generated by LSP was measured using the X-ray diffraction technique.

A section is adopted to analyze in agreement with the experiment. The finite element model of the section is shown in Fig. 4. The section is subdivided into 6000 elements.

TABLE 1 COMPOSITION OF SAE9310 (WT.%)

C	Mn	Pmax	Smax	Cr	Ni	Mo	Si
0.08-0.13	0.45-0.65	0.025	0.025	1.00-1.40	3.00-3.50	0.08-0.15	0.15-0.35

Results and Discussion

Fig.5 shows the propagation of shock wave. It can be found that the wave front reach 0.3mm, 0.6mm, 0.9mm at 50ns, 100ns, 150ns, the velocity is about 6000m/s. This is equal to the velocity of sound transmitting in the steel. The residual stress is acquired and becomes larger with the development of the propagation, as shown in Fig.5 (a), (c) and (e), whilst no residual stress is acquired in Y direction, as shown in Fig.5(b), (d) and (f).

Total equivalent plastic strain distribution after one pulse laser shock peening is shown in Fig.6. The region of the largest strain is the surface. The total strain is small, and the depth of the strain is about 0.6mm. The strain region area is equal to the laser spot. And the strain in other region is 0.

Fig.7 shows the comparison of the simulation results and experimental results of residual stress of SAE9310 after one pulse LSP. It can be found that the residual stress is decreasing first, and then increasing to 0 with the augmentation of the depth. From the surface to 0.2mm, the simulation results agree well with the experiment. The simulation residual stress is increasing to 0 abruptly when the depth is larger than 0.2mm. The largest depth is about 0.6mm, whilst the depth of experiment is about 3.5mm. The divergence between the simulation and experiment may be caused by the shock waves. In the simulation, the computation is stopped when the shock wave transmits from the surface to bottom of the specimen, and the effect of the carburized layer on the residual stress is not considered. This is the future work. Otherwise, the laser shock waves may transmit several times in the steel, whilst the one pulse LSP in the experiment is harder to perform. Owing to the limitation of the CPU time, the divergence is large between the simulation and experiment.

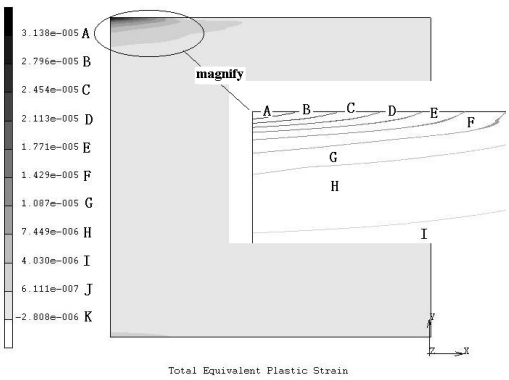

Fig. 6 Total Equivalent Plastic Strain Distribution

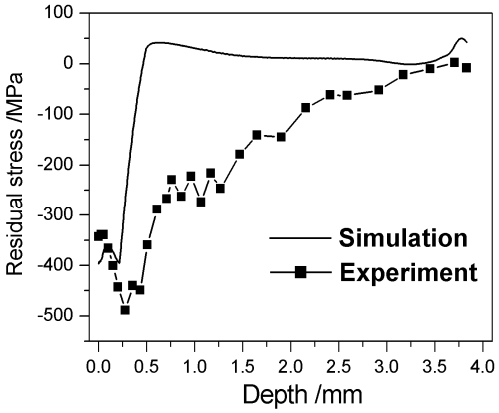

Fig.7 Comparison between Simulation and Experimental Residual Stress

Summary

The FE model of pulse laser shock peening is erected preliminarily. The FE model has been shown to forecast the residual stress and shock wave propagation. From the model it can be found that the residual compressive stress is mainly in X direction, whilst nearly 0 in Y direction. The largest strain is in the surface. With the increase of the depth, the strain becomes weaker. The strain region area is equal to the LSP spot. The residual stress is decreasing first, and then increasing with the increase of the depth from the surface. The divergence between the simulation and the experiment is due to the simplicity of the LSP conditions.

Keywords: hydraulic prop High frequency cladding temperature field

Abstract: The temperature field of mobile column is simulated, with the theory of high frequency induction heating and fourier heat conduction law , to analyze the change law of the temperature field with time, with different cladding parameters. The results show that the induction heating speed is mainly affected by power frequency of high frequency induction heating and cladding current. The higher frequency induction heating power is or the larger the cladding current is, the the faster the surface temperature of hydraulic prop is rising, the lower the inside-wall termperature and the less influenced the matrix is. The effect and the efficiency of cladding is comparatively superior when cladding frequency is 250KHz and current is 1160A.

Introduction

In mines, the environment is wretched, the air humidity is large, and operational equipments are in the corrosive environment for a long time. The mobile column of single hydraulic prop is exposed on the external surface of the upper part of oil cylinder, which can be corroded, crushed and damaged partially very easily in moist and corrosive environments. The traditional method is surface chromium plating [1-4], but electroplating production, with complicated technology and high cost will pollute the environment seriously, which is not accord with sustainable development policy in our country.

High frequency induction cladding has characteristics of averaged thickness of cladding layers, high strength and abrasive resistance and low production costs, becoming the hotspot of domestic and foreign researches gradually [5-8]. The author of this paper builds mobile column high frequency induction cladding tube wall temperature filed heat conduction model in accordance with induction heating principles, analyze the temperature distribution of mobile column matrix and alloy layers in different frequencies and cladding currents with Fluent6.3.

Mathematical Analysis of Mobile Column High Frequency Cladding Temperature Field

Mathematical model of temperature field analysis

The mobile column of hydraulic prop can be hollow cylinder work piece, its effective power in high frequency cladding P is [9-11]:

$$P = \pi\mu f L_2 F H_0^2 A = 4\pi^2 \times 10^{-9} \mu_r f H_0^2 L_0 F A \tag{1}$$

In the equation: μr is the relative magnetic conductivity of work piece, H/cm; f is high frequency induction heating power supply frequency, Hz; L0 is the length of work piece in high frequency cladding work head, cm; F is the cross section area of the outside-wall of work piece（cm2）, F=πR2（R is the outside radius of work piece, cm）; A is the function of hollow cylinder work piece; H0 is the magnetic strength of the surface of work piece, A/cm, which can be given by the following equation:

$$H_0 = \frac{B}{\mu_r \mu_0} \tag{2}$$

In the equation, μ_0 is vacuum magnetic permeability; B is work piece surface magnetic response strength, T, determined by equation (3):

$$B = 0.3nI\mu_0 \tag{3}$$

In the equation: n is the coil number of work heads of high frequency in unit length, r/m; I is the output current sent by high frequency induction heating power supply, A; μ_0 is vacuum magnetic permeability.

Value Calculation

In the process of high frequency cladding of mobile column, high frequency induction eddy layer is distributed on the surface of the matrix of mobile column firstly. With the progress of induction heating, alloy powders on the matrix surface melt, after the eddy layer reaches the surface of the alloy layer as the thermal source, it conducts in the inside-wall direction of mobile column by heat conduction until the surface layer of the matrix of mobile column melts and forms metallurgical combination with alloy so as to complete the entire high frequency cladding process. In the analysis of temperature field, the material of alloy powder is Ni45, the material of mobile column is 27SiMn（ ingredients of 2 materials are shown in Table 1）.

TABLE1 CHEMICAL COMPOSITION OF ALLOY POWDER AND MOBILE COLUMN[12] (MASS FRACTION,%)

	Ni	Cr	B	Si	Fe	C	Mn	S	P
Ni45 alloy layer	Bal.	12.5	1.9	4.1	6.6	0.34	—	—	—
27SiMn	≤0.03	≤0.03	—	1.1~1.4	Bal.	0.2~0.3	1.1~1.4	≤0.04	≤0.04

Considering that the mobile column is a revolution, distributed in the surrounding of eddy layer in high frequency cladding in average, mobile column and alloy layer are heated evenly. Therefore, we pick 1/4 for analysis to divide with simplified gridding and fasten the speed of analysis. At the same time, make following assumptions in the calculation and analysis of the temperature field:(1)Assume that alloy layer and matrix material is averaged, magnetic inductivity and heat inductivity of the material in each layer are the same; (2)ignore the heat lost by radiation between mobile column and alloy layer tube wall or air convection;(3)neglect the heat brought by water.

Value Simulation Calculation Results and Analysis

The temperature field of mobile column in high frequency cladding at different moments

Fig. 1 shows the tube-wall temperature distribution cloud figure of mobile column with high frequency induction heating power supply f is 250 kHz and cladding I is 1160A, diameter is 76mm, tube-wall thickness is 5mm and surface coating thickness is 0.5mm. Fig.1(a) shows the beginning of cladding, the eddy layer moves outside to the alloy layer from the surface of mobile column, large quantities of heat produces at the interface between the surface of mobile column and alloy layer and alloy powders near the eddy layer melt. Fig. 1(b) reveals that the eddy layer just moves to the most outermost layer of the alloy layer, at this time, the alloy powder layer has melted entirely (the outermost layer of alloy powders has reached 1150℃, the temperature at the interface between alloy and matrix has been 1100℃)，the eddy layer moving to the outermost surface of eddy layer continues to produce heat and conduct the heat to the inside matrix, alloy layer surface, tube-inside wall. Until the moment Fig. 1(c) shows, the thin layer of matrix forms the metallurgical combination with Ni45 alloy at this time, the cladding of the tube reaches the stability and the cladding of this segment of mobile column is completed. From the Figure, the outsourcing stage of the eddy layer takes approximately 1.4s, nearly occupying 60% of the total time of cladding.

(a) 0.1s (b)1.4 (c)2.3s

Fig.1 Temperature field at different moments during high frequency induction cladding

By simulation, we know that at the beginning moment, the temperature increases very rapidly, with the constant heating, the temperature rise becomes slow; in the latter period, for the limited thermal volume of mobile column, the heat absorbed by tube-walls starts to accumulate, the partial heating at the interface starts to be used to heat the material at the interface to make the interface temperature increases a little more rapidly. We also see from the Figure that, the temperature of the interface has been always over 1000℃ in 1.4-2.3s and as high as over than 1500 degrees in the heating later period, making the alloy and matrix at the interface have enough time to diffuse, permeate and form metallurgical combination.

(a)t_1=6.4s (b)t_2=8.9s

Fig. 2 Temperature field distribution cloud figure at t_1 and t_2 moment when f=10KHz and I=1160A

(a)t_1'=2.8s (b)t_2'=4.2s

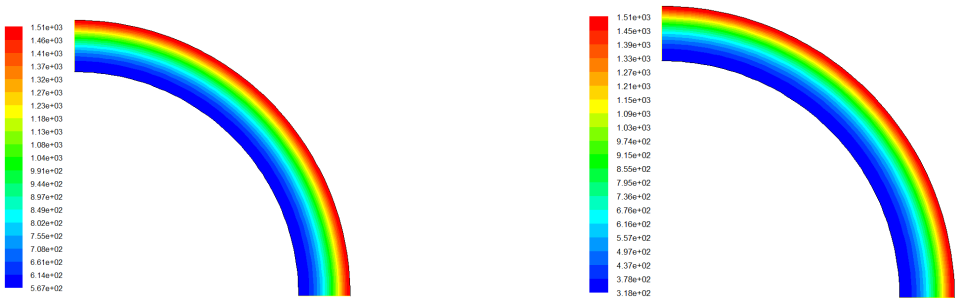

Fig. 3 Temperature field distribution cloud figure at t_1' and t_2' moment when f=50KHz and I=1160A

With the increase of frequency, the surface temperature of mobile column increases more rapidly, the time of high frequency cladding decreases and cladding efficiency becomes higher. The higher the efficiency is, the shorter the induction heating time is, the lower the inside-wall temperature of mobile column is when cladding is over. By contrasts, we can find that: the higher the frequency is, the more rapidly the surface temperature of work piece is rising, the tube inside-wall temperature cannot catch up to reach the high temperature within the short time, metallurgical combination has occurred at the interface between alloy layer and matrix, which are characteristics of high frequency induction heating; when using low frequency, the power density of skin layer is low, the surface temperature of work piece increases slowly, the surface heat gradually conducts to the mobile column wall, the temperature of tube wall gradually increases, the tube temperature has reached over a thousand degree when the cladding is over (or almost the same with the surface temperature), which would cause serious thermal destruction, deformation on the matrix and the flowing of alloy powder of melting status.

Effects of High Frequency Cladding Currents

Select f=250KHz，I=850, 1000, 1160A to calculate and simulate separately and obtain the work piece temperature field distribution cloud chart in different cladding currents when high frequency induction heating is over（as Fig. 4 and Fig. 1（c））. We can know from the Figure that: when cladding

current are chosen 850, 1000 and 1160A separately, induction heating time are 5.5s, 3.5s and 2.3s separately, the inside-wall temperature of mobile column when induction heating is over is 567℃, 318℃ and 177℃ separately.

（a）I_1=850A，T_1=5.5s (b)I_2=1000A，T_2=3.5s

Fig. 4 Work piece temperature field distribution cloud figure in different cladding currents when heating is over

With the increase of cladding current, the surface temperature of work piece raises more rapidly, cladding efficiency improves; when induction heating is done, the inside-wall temperature of mobile column reduces with the increase of cladding current. When using higher cladding current, power density of skin layer is high in unit volume, mobile alloy layer can reach the high temperature within the short time, but the inside-wall temperature inside the mobile column cannot catch up to reach the high temperature, making the structure and mechanical performance of the matrix basically not change at all; when using lower cladding current, the induction current density of skin layer is low in unit volume, the surface temperature of mobile column increases slowly, the quantity of heat in the alloy layer gradually conducts to the matrix layer, making the inside-wall temperature in the mobile column increases to 567 degree when induction heating ends, which seriously damages matrix materials and even causes the flowing of alloy in the coating.

Conclusion

(1) In mobile column high frequency cladding, high frequency heating power efficiency mainly affects cladding efficiency and effect. With the rise of frequency, the surface temperature of mobile column raises more rapidly, the temperature difference between tube surface and inside-wall increases and the thermal effect on the matrix reduces.

(2) In mobile column high frequency cladding, cladding current mainly influences cladding efficiency. In certain ranges, with the increase of the current, the surface temperature of mobile column rises more rapidly, the temperature of inside-wall tube reduces when induction heating ends and the thermal effect of induction heating on the matrix reduces.

(3) When frequency is 250KHz, cladding current is 1160A, cladding efficiency and effect is good.

Cfd Simulation On Hydrodynamics Of Liquid-Liquid Slug Flow In Microchannel

Wang Yi[1,a]

Department of Pharmacy, Tianjin Medical College, Tianjin 300222, China

[a]wangyii_2013@163.com

Keywords: CFD simulation; liquid-liquid; slug flow; microchannel.

Abstract: Hydrodynamics in a liquid-liquid slug flow in a T-junction microchannel of 600μm diameter, operated under a squeezing regime, was simulated with the computational fluid dynamics method. The slug flow generation simulated shows very good agreement with experimental snapshots where the clear slug formation takes place in the vicinity of the T-junction. The internal circulation within each slug was also obtained, which could make us better understand the hydrodynamics of liquid-liquid slug flow in microchannel.

Introduction

Liquid–liquid slug flow is a flow of two immiscible liquids, characterized by a series of liquid slugs of one phase separated by the other. Since both phases move alternatively, each slug serves as an individual processing sub volume which is highly regular and guarantees well defined interfacial area for transfer processes. The liquid–liquid slug flow microreactor has been demonstrated to be a useful instrument for the enhancement of heat and mass transfer limited reactions[1]. The mass transfer arises by two mechanisms: convection through the internal circulations within each slug and diffusion between two adjacent slugs. The internal circulations within both slugs resulted from the shear between the wall surface and the slug axis renew the interface and enhance the diffusive penetration.

Several liquid-liquid slug flow microreactors with different types of two-phase mixing elements such as T-type[2] and Y-type[3] have been used for experimentation in the laboratory. Garstecki et al. (2006)[4] used a T-type mixing element where the dispersed phase was introduced in the continuous flow channel at a right angle and proposed a correlation for slug length as a function of the ratio of dispersed to continuous phase flow, which was found to be independent of flow velocity. Recently, Dessimoz et al. (2008)[5] used both types of mixing elements (T and Y) and reported the effect of mixing element on the two-phase flow patterns. In the case of Y-type element the pressure drop is less when compared with T-type mixing elements as frictional losses are lower in the former case. Thus, to understand the slug flow generation mechanism, more work is needed.

The numerical method can provide information that might not be available directly by experiments, such as pressure fluctuation in a very short time, flow fields in any profile without the influence of tracers, etc. Several CFD studies are available on the behavior of liquid-liquid two-phase slug flow in the microreactor. Kashid et al.[6] performed two-dimensional (2-D) simulations of liquid-liquid slug flow in a microchannel to investigate liquid recirculation in the slugs. In their simulations, the shape of the slug was assumed to be fixed and the slugs were modeled to be stationary with a moving wall boundary condition. Wu et al.[7] performed 2-D

simulations of a liquid-liquid flow in a cross-junction rectangular microchannel using the lattice-Boltzmann method. They investigated the effects of Capillary number (Ca) and Weber number (We) on the slug formation mechanism. Kashid et al.[8] performed 2-D VOF simulations of liquid-liquid slug flow through a T-junction microchannel for Ca < 0.01 and validated the results using the experiments of Tice et al.[9].

In view of the above summary, detailed work on the process occurring in the two-phase contacting zone of microchannels is still inadequate. Therefore, in this paper, we designed a 2D T-junction microchannel with water and oil inlets located head-to-head and investigated the slug formation process. A VOF based CFD methodology is developed to investigate the slug flow generation in a T-type mixing element considering the wall film.

Numerical methods

In immiscible liquids, the movement of interface is important in evaluating the performance of the reactor, and therefore, free-surface modeling is necessary. Different methods are available to model immiscible fluids such as level set, volume of fluid (VOF), Lattice Boltzmann and so on[10]. VOF and level-set approaches belong to the most common implicit free-surface reconstruction methods, while, particularly, VOF is relatively simple to treat topological changes of the interface and is naturally conservative. The finite volume calculus in the commercial computational fluid dynamics (CFD) package of FLUENT 6.3.26 was used for the numerical simulations. The VOF model provided by FLUENT was employed to track the interface of water and oil, and the continuum surface force (CSF) was adopted to include the surface tension in the momentum equation. The governing equations for the present simulations are as follows:

equation of continuity:

$$\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \vec{v}) = 0 \tag{1}$$

equation of motion:

$$\frac{\partial (\rho \vec{v})}{\partial t} + \nabla \cdot (\rho \vec{v} \vec{v}) = -\nabla p + \nabla \cdot [\mu (\nabla \vec{v} + \nabla \vec{v}^{T})] + \rho \vec{g} + \vec{F} \tag{2}$$

volume fraction equation:

$$\frac{\partial \alpha_k}{\partial t} + \vec{v} \cdot \alpha_k = 0 \tag{3}$$

where

$$\rho = \alpha_1 \rho_1 + \alpha_2 \rho_2, \quad \mu = \alpha_1 \mu_1 + \alpha_2 \mu_2$$

The model geometry is illustrated in Fig. 1, where d = 600μm, and the lengths of the water and oil inlets, the contacting zone and the main channel are 2d, 2d, d and 10d, respectively. It was meshed with the preprocessor GAMBIT. A grid independence study was performed by varying the number of grid cells in the model geometry. Based on this study, the number of grid cells was determined to be 15,340. The gravity effect was neglected in the whole process. The boundary conditions were velocity inlet for the water and oil inlets, outflow for the outlet, and no-slip condition for all walls. The PISO scheme was chosen for pressure-velocity coupling. In the simulations, time step and relaxation factors were adjusted to ensure convergence.

Two-phase fluids are n-butyl acetate and 0.4M NaOH aqueous solution, whose densities are 877 and 1015kg/m^3, respectively. The interfacial tension σ between two phases was set to 0.25N/m and the contacting angle was set to 60 degree according to the snapshots acquired by experimental method.

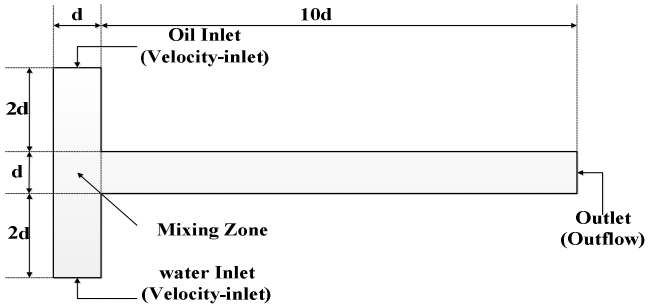

Fig. 1 - Schematic of geometry and boundary conditions used in present work.

Results and discussion

In the simulation method, two immiscible liquids were introduced into the mixing element considering that the microreactor is initially filled with the continuous phase. The interpenetration of two streams in the vicinity of the junction generates the characteristic alternating slug flow structure.

In general, two different mechanisms for slug formation in microchannel are proposed: dripping and squeezing regime. The capillary number Ca is the criterion to distinguish the two phenomena. When the capillary number is larger than 0.01, shear stress plays a leading role and the dripping regime arises. In this case, the dispersed fluid occupies only part of the cross-section when it enters the main channel. If Ca is smaller than 0.01, the interfacial force dominates the shear stress and the squeezing regime appears; then, the dispersed fluid fills almost the entire cross-section and blocks the continuous phase until it breaks off. The squeezing regime is considered to be specific to microdevice and becomes the focus of our present studies.

A typical process of slug formation with squeezing regime we studied can be described in four stages (Fig. 2) as explained as follows:

(a) Initially, The two immiscible fluids form an interface at the junction of the inlet and main channel. The stream of the dispersed phase penetrates into the main channel and a droplet begins to grow.

(b) As the tip of the dispersed phase grows, it blocks almost the entire cross-section of the main channel. The continuous phase then flows through the space between the wall and the dispersed phase droplet with high velocity.

(c) The pressure gradient along the length of the channel and the shear exerted by the continuous fluid distort the droplet in the downstream direction. The drop elongates and grows downstream. When the interface approaches the downstream edge of the inlet for the dispersed phase, the neck connecting the inlet channel with the droplet breaks and a slug is formed in the main channel.

(d) The disconnected slug flows downstream along the main channel, while the tip of the stream of dispersed phase retracts to the end of the inlet and the process repeats.

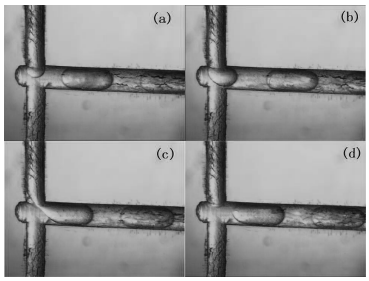

Fig. 2 - Four steps of slug flow generation with laboratory experiment.

The simulated snapshots corresponding to the experimental operating conditions of Fig. 2 are depicted in Fig. 3. The results show very good agreement with experimental snapshots where the clear slug formation takes place in the vicinity of the T-junction.

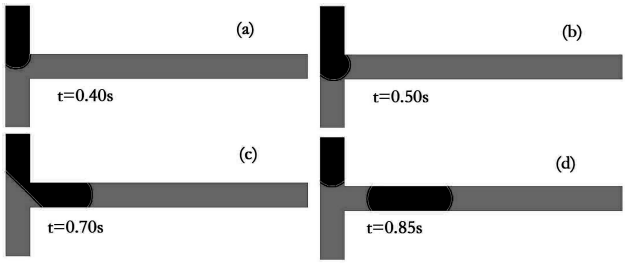

Fig. 3 - CFD simulated snapshots for the operating conditions corresponding to Fig. 2.

Conclusion

Simulations were conducted in a liquid-liquid two-phase microchannel to investigate the hydrodynamics of slug flow with computational fluid dynamics method. The slug flow generation with squeezing regime in the T-junction geometries studied was described in four stages. The simulated results was compared with experimental snapshots and showed good agreement. The internal circulation within slugs was also presented, which can intensify mass transfer.

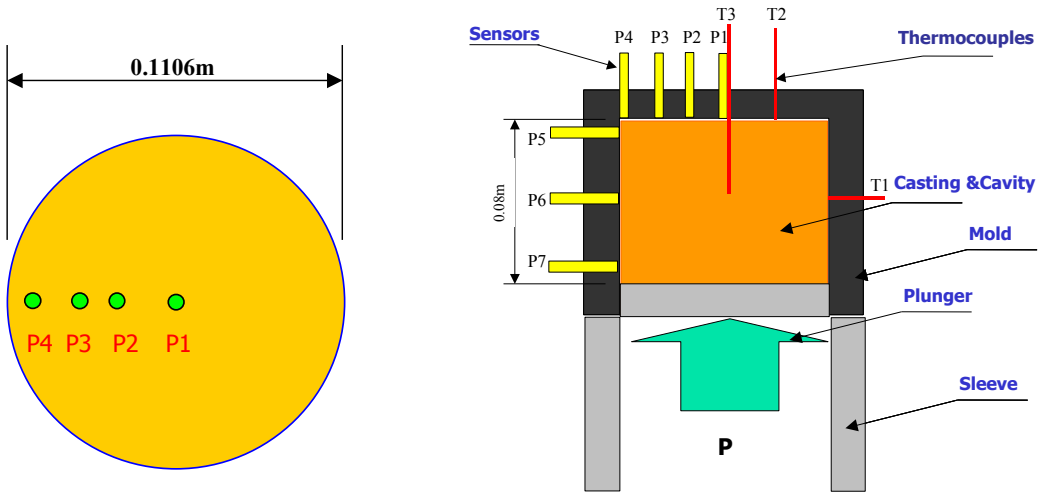
Abstract: In this study, the experimental measurement of the pressure distribution in a cylindrical die cavity for squeeze casting of magnesium alloy AM50A was carried out. Piezo-electric quartz pressure transducers were integrated into a die cavity for real-time pressure measurements. The experimental results revealed that local cavity pressures at various locations changed with time in the duration of squeeze casting solidification and cooling. The pressure transfer rate varied considerably within the casting geometry. The distribution of local cavity pressures was inhomogeneous in the cavity.



Introduction

During squeeze casting, the cavity pressure usually is not considered as the first process parameter. Instead, the hydraulic pressure is measured and used as specific pressure, or the cavity pressure is even eliminated as a quality control variable by simply using large machine which provide as high press load more than that required [1]. The main reason is that the real characteristics of the cavity pressure in squeeze casting had yet to be fully understood.

Due to the extreme hostile environment of squeeze casting cavity (thermal, mechanical and chemical conditions in the die), there are few reliable pressure sensors which can withstand such conditions. Hence, measuring local cavity pressures directly inside the die becomes an extremely challenging task. It is not surprised that, despite of the presence of numerous publications [1-8] on squeeze casting, very few of them are related to the characterization of cavity pressures. Thus, the principal objective of this study is to elucidate a fundamental understanding of pressure distribution in die cavities during squeeze casting of magnesium alloys AM50A due to its potential application in automotive components.

Experimental setup and procedures

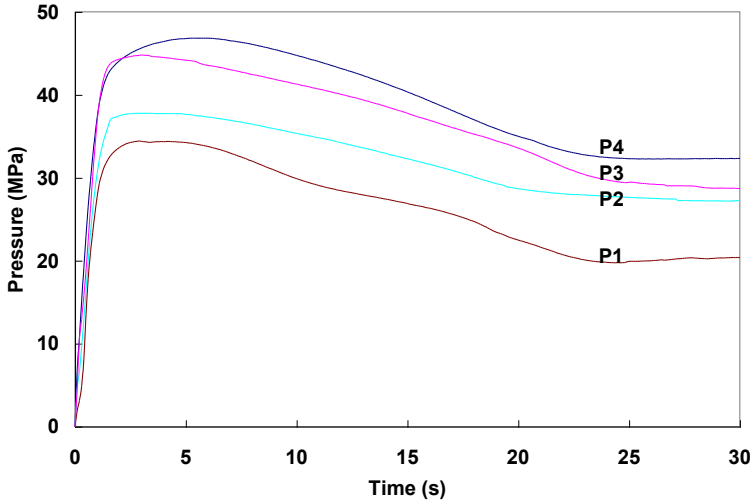
A squeeze casting setup utilized in this study consisting of A 75 tons laboratory hydraulic press, a die, an electric resistance furnace and a data acquisition system, which includes the press and mold assembly consisting of the die, sleeve and plunger. The mold assembly was composed of two parts, i.e., the upper die of casting cavity with a diameter of 0.102 m and a height of 0.097 m; and the bottom sleeve with a diameter of 0.102 m and a height of 0.127 m. This combination enables to make a cylindrical coupon with a diameter of 0.102 m and a height of 0.080 m (Fig. 1). Both the upper die and the bottom sleeve were heated by Acrolab (Acrolab Ltd. in Windsor, Ontario, Canada) ceramic band heaters, of which temperatures were separately controlled by Shinko (Shinko Electric Industries Co., Ltd. in Tokyo, Japan) Temperature Controllers. The detailed description of the setup are given in reference 9.

(a) (b)

Figure 1. Scheme diagram showing the locations in which pressure transducers and thermal couples are embedded in the system, (a) top view, and (b) cross-section view.

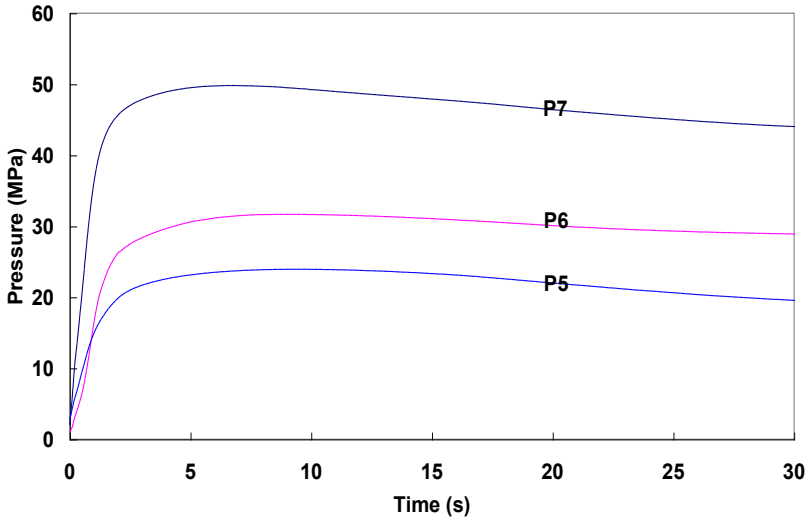
Kistler pressure transducers Type 6175A2 were employed to directly measure in-cavity pressures. As show in Fig. 1, four pressure transducers (P1, P2, P3 and P4) were inserted into the cavity through the top wall of the die. The sensing tips of the transducers were flush to the inner top die surface. Transducer P1 was positioned at the center of the inner top die surface. In the radial direction, transducers P2, P3 and P4 were arranged 0.020, 0.030 and 0.040 m away from the centerline of the casting, respectively. Along the inner side die surface, three transducers (P5, P6 and P7) were placed 0.010, 0.040 and 0.070 m downward from the inner top die surface. Due to the contour shape of the inner side die surface, an extension pin with a diameter of 0.011m and a length of 0.025 m was placed in front of the tip of each transducer for preventing potential damage resulting from melt cavity filling. The front surfaces of the pins were machined to accommodate the contour shape of the inner side die surface for the accuracy of pressure measurements. Real-time pressure data were recorded at regular intervals of 100ms over the entire user-defined period of measurement during the pressurized solidification stage of squeeze casting.

A Lindberg electric resistance furnace was employed to melt magnesium alloy AM50A held in a mild steel crucible with a maximum holding capacity of 4 kilogram. The melt temperature was regularly monitored by a digital thermometer (Omega HH509) during melting. The molten metal was poured directly from the crucible into the sleeve to minimize the loss of melt superheat once it reached a desired temperature. Protection gas (Sulfur Hexafluoride SF_6 0.5% + carbon dioxide CO_2) was used during both melting and casting magnesium alloys to protect the melt from any excessive oxidation or possible burning. A data acquisition system (DAS) containing a National Instruments PCI-6033E processor with eight temperature (K type) channels and eight sensor channels was employed.



The squeeze casting operation procedures are summarized as follows: (a) preheating and the graphite-lubricated die to 275 ^{0}C, and selecting the operating parameters; (b) pouring molten magnesium alloy AM50A into the shot sleeve until it reached 695 ^{0}C; (c) injecting the melt into the die cavity by the plunger with an upward velocity of 0.055m/s once the die was closed by moving up the lower platen with the sleeve; (d) applying a predetermined pressure to the solidifying melt for a preset dwell time upon the completion of; and (e) retracting the plunger and the lower platen to its original position, and ejecting the cast coupon.

Results and discussion



Local Pressure Change with Time

Fig. 2(a) presents the local in-cavity pressure change with time at four locations along the top surface of the casting during the pressurized solidification step of squeeze casting when the external

pressure was applied. P1, P2, P3, and P4 represent the pressure histories at the transducer-embedded locations. It is evident from Fig. 2(b) that the local cavity pressures at all the sampling locations built up very rapidly after the cavity filling completed once the external force was applied. Then, at each location, the local pressure reached its own peak before starting to decrease. It took less than 5 seconds for P1, P2, P3 and P4 increased to their peak values of 47, 43, 38 and 34 MPa from 0 MPa, respectively. Along the top surface, the peak values of the local pressures increased as the distance of the sampling locations away from the centerline of the casting extended. Around 25 seconds after the applied pressure set in, the individual local pressures decreased to its own stable plateau.

(a)

(b)

Figure 2. Typical experimental results of local pressure measurements on the (a) top surface, and (b) the side surface of a cylindrical squeeze casting of magnesium alloy AM50A under applied pressure of 70MPa.

The variation of the local pressure with time along the side surface of the casting is shown in Fig. 2(b). As can be seen from Fig. 2(b), the local pressures at locations P5, P6 and P7 increased quickly to the highest points, 23, 37 and 50 MPa respectively after the external force was applied. This indicates that the individual local pressure along the side surface decreased when the casting height increases. All the local pressures decreased slowly afterward.

Variation of Pressure Transfer Rate and Temperature

Examination of Fig. 2(a) and 2(b) manifests that, at the beginning of the external force application, the local pressures increased up to 95% of its peak value along the top surface in a much faster pace than that at the side surface of the casting despite that the local pressures along the top surface decrease considerably faster than those at the side surface after a certain period of time. For the clarification of discussion, the increasing rate of the local pressures up to 95% of its peak

value is defined as an initial local pressure transfer rate thereafter in the text. Fig.3 compares the initial pressure transfer rates on the top surface to those at the side. The pressure transfer rate on the top surface varies from 19 to 30 MPa/s with an average of 23 MPa/s. But, at the side surface, the average pressure transfer rate is only around 12 MPa/s.This observation suggests that the pressure transfer in a direction perpendicular to the external force is faster than that in a parallel direction.

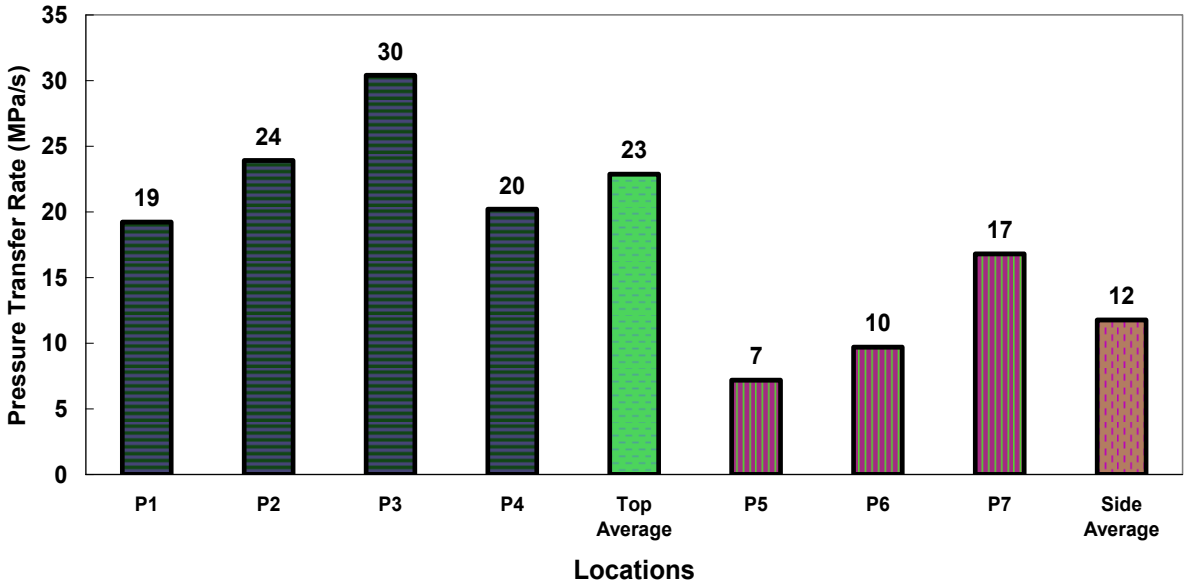


Figure 3. Initial local pressure transfer rates on the top and side surfaces of a cylindrical squeeze casting of magnesium alloy AM50A.

Pressure Distribution on Casting Surfaces

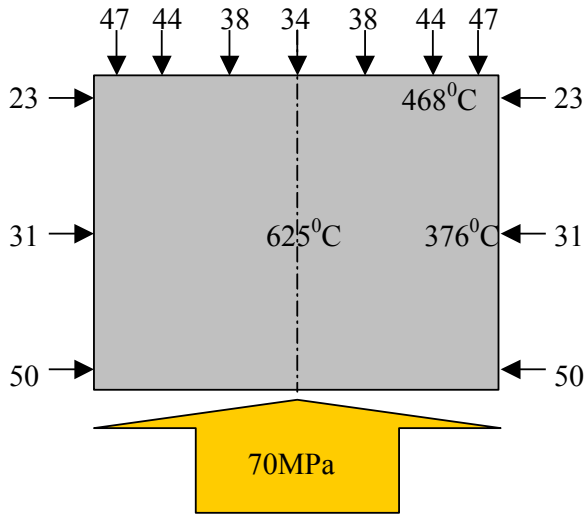

Figure 4. Initial pressure distributions 5 seconds after an external pressure of 70 MPa being applied.

A pressure distribution along the top and side surfaces of the cylindrical casting 5 seconds after the completion of the cavity filling under the applied pressures of 70 MPa with three instantaneous temperature measurements at the top, side and center of the casting is shown in Fig. 4. There was an increase in the pressure from 34 to 47 MPa as the distance from the center increases on the top surface. All the measured pressures were much lower than the original applied pressure of 70 MPa. Along the casting side, the pressure decreased considerably to 23 from the original applied pressure of 70 MPa with increasing the height from the bottom to the top of the casting. It is evident that the pressure distribution was inhomogeneous on either the side or top surfaces of the casting. This finding contradicts the existing viewpoint about squeeze casting, i.e., “molten metal is solidified under applied hydrostatic pressure” [10, 11].

Summary

The experimental investigation has been undertaken to obtain an understanding of transient pressure behavior in squeeze casting of magnesium alloy AM50A. The in-cavity pressures were directly measured. The results showed that that local cavity pressures at various locations changed with time in the duration of casting solidification and cooling. The pressure transfer rate varies considerably within the cylindrical geometry of the casting. The pressure transfer in a direction perpendicular to the external force is faster than that in a parallel direction.

Keywords: AgCu28, AuCu20, oxygen-free copper, microstructure, mechanical properties

Abstract：The microstructure and mechanical properties of brazed joints of oxygen-free copper and oxygen-free copper, nickel-plated kovar, monel, nickel-plated stainless steel were respectively studied by using AgCu28 and AuCu20 filler metal. Effects of different filler metal on microstructure of the brazed joints were analyzed through metallurgical microscope, SEM, EPMA. The brazed joints tensile strengths were analyzed through tensile test. The results indicate that the brazing process of oxygen-free copper and nickel content alloy used AgCu28 filler metal, nickel element is easy to diffused into AgCu28, AgCu28 filler metal with nickel element wetting spreadability along grain boundary of the oxygen - free copper, resulting in the penetration of the grain boundary of the oxygen-free copper. The joints brazed by AuCu20 filler metal have the better performance than the joints brazed by AgCu28 filler metal.

Introduction

Electronic devices, such as multi-beam klystron, space traveling wave tube, high power klystron, are widely used in the field of basic research in physics, chemistry, information and the field of technical in communications, radar, medical diagnosis and treatment. There are nearly one hundred processes in the production of electronic devices, including metal brazing, welding, electronic spot welding.

Materials currently used in electronic devices are copper and copper alloys, nickel and nickel alloy, iron and steel, tungsten and molybdenum, tantalum and niobium, zirconium titanium and beryllium expansion alloy. These materials usually bonding by brazing. So far, there are few data on the microstructure and mechanical properties of brazed joints of oxygen-free copper, nickel-plated kovar, monel, nickel-plated stainless steel used in electronic devices.

The microstructure and mechanical properties of brazed joints of oxygen-free copper and oxygen-free copper, nickel-plated kovar, monel, nickel-plated stainless steel were respectively studied by using AgCu28 and AuCu20 filler metal. Through the analysis of the brazed joints performance, provide data support and technical guidance for production of electronic devices.

Experimental Procedures

The base metal used in the experiments were oxygen-free copper, nickel-plated kovar, monel and nickel-plated stainless steel. The base metals were brazed by butt. AgCu28 and AuCu20 were used

as filler metal.OlympusBX51M metallurgical microscope and JSM-5800 scanning electron microscope was used to observe and detect the microstructure and major element content distribution of the brazed joints. Joints tensile strength of each sample is the average of the five joints tensile strength. Table1 gives the major chemical composition of oxygen-free copper, nickel-plated kovar, monel and nickel-plated stainless steel.

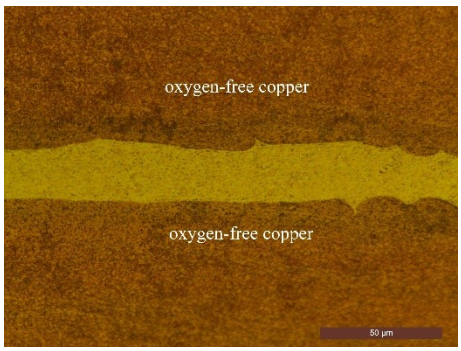

TABLE1 MAJOR CHEMICAL COMPOSITION OF BASE METALS (WT%)

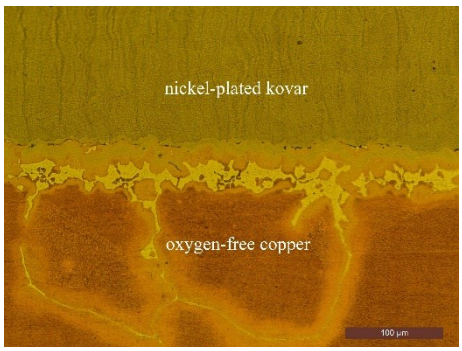
base metal	Cu	Fe	Ni	Mn	C	Co	Si	Cr
oxygen-free copper	≥99.97	0.005	0.002	-	-	-		-
kovar	-	rest	32.1～33.6	0.05	-	14.0～15.2	0.30	-
monel	38.0～42.0	≤1.0	rest	1.25～2.25	0.3	rest	0.75	-
stainless steel	-	-	8.25～10.50	≤2.00	≤0.08		≤1.00	18.00～20.00



Results and Discussion

Microstructure of joints brazed by AgCu28 filler metal

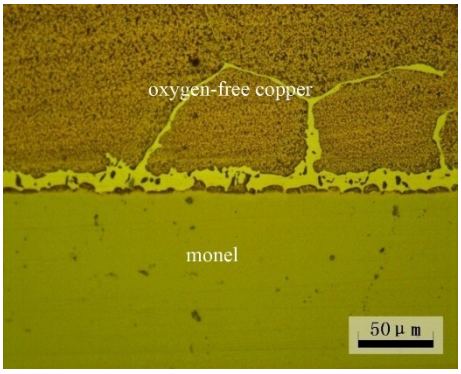


Figure 1 shows the microstructure of joints brazed by AgCu28 filler metal. As shown in Fig.1(a), the brazing seam is completely filled with AgCu28 filler metal. AgCu28 filler metal melts uniformity, having good wetting effect with oxygen-free copper. No defects existed in the brazing seam. Fig.1(b)-(d) show the microstructure of brazed joints of oxygen-free copper and nickel-plated kovar, oxygen-free copper and monel, oxygen-free copper and nickel stainless steel. In joints of oxygen-free copper and nickel content alloy brazed by AgCu28 filler metal, grain boundary penetration was occurred in oxygen-free copper after brazing. The depth of AgCu28 eutectic liquid penetrating into oxygen-free copper grain boundaries is about 100μm.

Fig.1 Microstructure of joints brazed by AgCu28 filler metal

As shown in Fig.2(a),the brazing seam of oxygen-free copper and oxygen-free copper distributed Ag (Cu) solid solution. Fig.2(b) shows the result of major element content distribution of the brazed joints of oxygen-free copper and nickel-plated kovar. Nickel element in the base metal was observed to be diffused into AgCu28 filler metal. Nickel element distribution in other joints brazed by AgCu28 filler metal are similar with that of the brazed joint of oxygen-free copper and nickel-plated stainless steel.

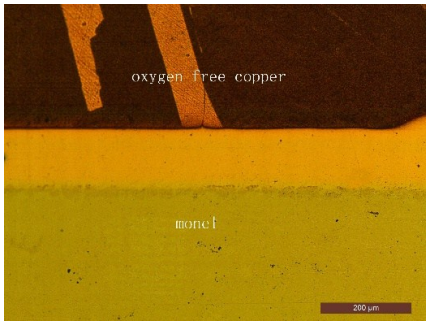
Fig.2 Major Element Content Distribution of Joints Brazed by AgCu28 Filler Metal

Microstructure of joints brazed by AuCu20 filler metal



As shown in Fig.3，the microstructure of the joints brazed by AuCu20 filler metal are significantly different from that of the joints brazed by AgCu28 filler metal. The brazed joints of oxygen-free copper and oxygen-free copper, oxygen-free copper and nickel-plated kovar, oxygen-free copper and monel, oxygen-free copper and nickel-plated stainless steel obtained nearly best microstructure . AuCu20 filler metal melts uniformity, having obvious boundary with base metal and good wetting to surface of the base metal, no defects existed in the brazing seam.

Fig.3 Microstructure of Joints Brazed by AuCu20 Filler Metal

As shown in Fig.4(a), the boundary oxygen-free copper slightly dissolved and copper element was observed to be dissolved into AuCu20 filler metal. The more close to the oxygen-free copper base metal, the mass fraction of copper element is higher. This kind of phenomenon exists in all joints brazed by AuCu20 filler metal.

Strength of brazed joints

Fig.5 shows the tensile strength test result of the brazed joints. Tensile testing specimens using AgCu28 as filler metal fractured at the base metal with the joint strength over 220MPa, expect for the testing specimens of oxygen-free copper and nickel-plated stainless steel. Tensile testing specimens using AuCu20 as filler metal fractured at the base metal with the joint strength over 215MPa.

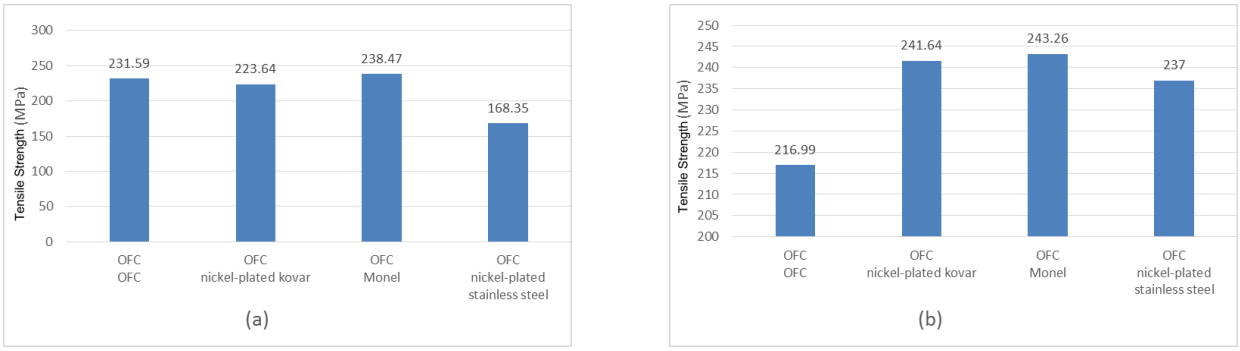

Fig.5 Tensile Test Results of Specimens Brazed by AgCu28 Filler Metal（a），AuCu20 Filler Metal（b）

Discussion

The experimental results show that the microstructure of joints brazed by AgCu28 filler metal vary along with the base metal. The joint of oxygen-free copper and oxygen-free copper brazed by AgCu28 filler metal has good performance, however, the other joints brazed by AgCu28 filler metal are found that filler metal penetrates along the grain boundaries of oxygen-free copper. The joints brazed by AuCu20 filler metal obtained nearly best microstructure.

The joint of oxygen-free copper and nickel-plated stainless steel brazed by AgCu28 filler metal fractured at the brazing seam, and the other brazed joints fractured at oxygen-free copper in tension test.

Comprehensively, the joints brazed by AuCu20 filler metal have the better performance than the joints brazed by AgCu28 filler metal.

Summary

(1) The microstructure of joints brazed by AgCu28 filler metal vary along with the base metal. The brazed joint of oxygen-free copper and oxygen-free copper has good performance, however, the other brazed joints brazed by AgCu28 filler metal are found that filler metal penetrates along the grain boundaries of oxygen-free copper.

(2) Nickel elements which base metal contains diffuse into AgCu28 filler metal, however, no obvious diffuse occurred at the joints brazed by AuCu20 filler metal in tension test.

(3) The joint of oxygen-free copper and nickel-plated stainless steel brazed by AgCu28 filler metal fractured at the brazing seam, and the other brazed joints fractured at oxygen-free copper.

Keywords: Diamond; Hydrothermal method; Chemical duplex plating; Electorless plating; Surface metallization; Heat treatment

Abstract: As a surface of diamond has a higher interfacial energy and worse binding force, the diamond shed from matrix easily. For solving this, the microstructures and properties of the metallic coating on diamond surface were studied. The different temperatures, such as 110, 120, and 130 ℃ for 6 h, were used for coating diamond in the high-pressure reactor respectively. The structure and performance of the metallic coating on diamond surface were tested by Scanning Electron Microscopy (SEM), X-ray Diffraction (XRD) and diamond compressive strength instrument. The results showed that a continuous and compact coating of Ni, W and Ti on the diamond surface is obtained by the hydrothermal coating technology (chemical duplex plating) at 120 ℃. After heat treatment at 850 ℃ for 1 h, the better layer coatings form for protecting diamonds and reducing the trend of oxidize. Because the carbides of W and Ti present at the boundries between the coating and diamond surface, the combination of chemistry and metallurgy is gotten. The compress strength of diamonds after hydrothermal and heat treatment is higher than that of uncoated particles (those are 54.40% and 85.48%, respectively).

Introduction

A reaction environment which can make of less soluble or insoluble material dissolved and crystallized is created at high-temperature (100-1000 ℃) and at high-pressure (1-100 MPa) by using aqueous solution and heating reaction container [1]. The high purity, good homogeneity and strong combination substrates of a thin film are gained at lower temperatures by hydrothermal method [2, 3]. The method of hydrothermal is low cost, simple equipment and the grain size controlled in the forming thin film [4, 5].

The problem of diamond shedding from diamond tools has not been completely solved by far, it makes the efficiency and life of diamond tools reduce [6]. The metallization can be adopted for the metal layers which contain carbide forming elements coating on the diamond surface. The metallurgical binding between coating and diamond is formed by heat treatment, which metallic carbides are presented by the carbide forming elements reacting with carbon in the diamond. This lessens the shedding tendency of diamond [7, 8]. The coating layers of Ni-W-P are formed on the diamond surface by electroless plating [9], but the contents of strong carbide forming elements W is fewer, and the effects of metallurgical binding is limited. The layers contain Ti powders are deposited on the layer of Ni-W-P by chemical duplex plating (hydrothermal). When Ti and W react with carbon on diamond surface, the chance of forming carbide increase, the binding strength and wear resistance of diamond improves, and their cutting performance and the life of the product enhance [10-12].

Experiment

Experimental Methods

In this experiment, MBD50/60 diamond particles were used for electroless plating Ni-W-P. Then we put them into the reactor with reaction medium, and hydrothermal reaction carried out in IOIB-2 thermostats. Heat treatment performed in the experimental box-type resistance furnace. The surface morphology and composition distribution of diamonds were tested by JSM-6380LA scanning electron microscope and JXA-8800R electron probe. The produced phases studied by XRD (Rigaku D/MAX-Ra, CuK_{α}, 40kV×50mA, λ=1.54184 Å). The compressive strength of diamonds was tested by ZMC-Ⅱ diamond using hydrostatic strength meter.

Experimental Process

The technologic process of chemical duplex plating showed in Fig.1.

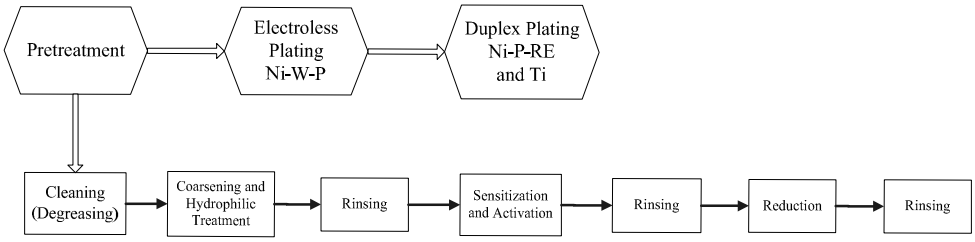

Fig.1 The technologic process of chemical duplex plating.

Pretreatment

Because the diamond belongs to nonmetallic crystals, its chemical properties are so stable. Therefore, it does not have the role of the surface catalytic activity. The catalytic center of palladium on diamond surface can be form by pretreatment including sensitization and activation (Fig.1), and the center can make Ni and W plasma deposite on diamond surface. For this, we adopted the salt-based colloid palladium.

Electroless Plating

Ni is elected as inducing metal to reduce the dissolving erosion of the diamond coating layer [13]. In diamond tools, W, which has good chemical binding affinity with the carbon atoms in diamond and does not damage diamond, considered the best binding metal of diamond. The solution made of $NiSO_4 \cdot 6H_2O$ 6～10g/L, $Na_2WO_4 \cdot 7H_2O$ 32～38g/L, $NaH_2PO_2 \cdot H_2O$ 8～12g/L, $Na_3(C_6H_5O_7) \cdot 2H_2O$ 4～10g/L, $C_3H_6O_3$15～20mL/L, trace stabilizer and pH 8.0~8.4. The temperature of electroless plating Ni-W-P is 90~95℃, and the plating time is 1h. The speed of stirring is moderate.

Chemical Duplex Plating (Hydrothermal)

If chemical duplex plating brought into effect after sensitization and activation, the catalytic activity on diamond surface would be destroyed because of metal Ti powders adsorbed on the layer of sensitization and activation [13]. Therefore, the technology of hydrothermal duplex plating Ti must be used after electroless plating. The solution made of $NiSO_4 \cdot 6H_2O$ 27g/L, $NaH_2PO_2 \cdot H_2O$ 30g/L, $Na_3C_6H_5O_7 \cdot 2H_2O$ 8~12g/L, $C_3H_6O_3$ 28~30mL/L, $C_4H_6O_4$ 1~4 g/L, $C_4H_6O_6$ 2~4 g/L, Rare Earth 0.5~1.0 g/L, Titanium 2~5 g/L, trace stabilizer and pH 4.0~5.0. The temperature of hydrothermal duplex plating is 110~130℃, and the plating time is 6h.

Heat Treatment

The heat treatment can make carbides (such as WC, TiC) form. The chemical and metallurgy combination between coating layer and diamond surface was achieved. According to the literature [14], the composition, structure and formation conditions of compounds is Ti/diamond:＞873K(600℃), TiC; W/diamond:＞973K(700℃), WC. The heat temperature must be above 700℃to forming carbide, and it may be below 900℃ for avoiding thermal damage. The heat treatment process was selected for 1h at 850℃.

Results and discussion

Surface Morphology and Composition Analysis

Surface Morphology and Composition Analysis after Electroless Plating Ni-W-P

The surface morphology of diamond particles after electroless plating by SEM shows in Fig.2(a). The coating which is complete, uniform and dense on diamond surface is observed. When the coating is enlarged, the particles (see Fig.2(b)) which are more uniform size, round cellular on the coating are observed. The composites of coating are analyzed by EPMA. It presentes in Fig.2(c) the main element is Ni and then is W, P.

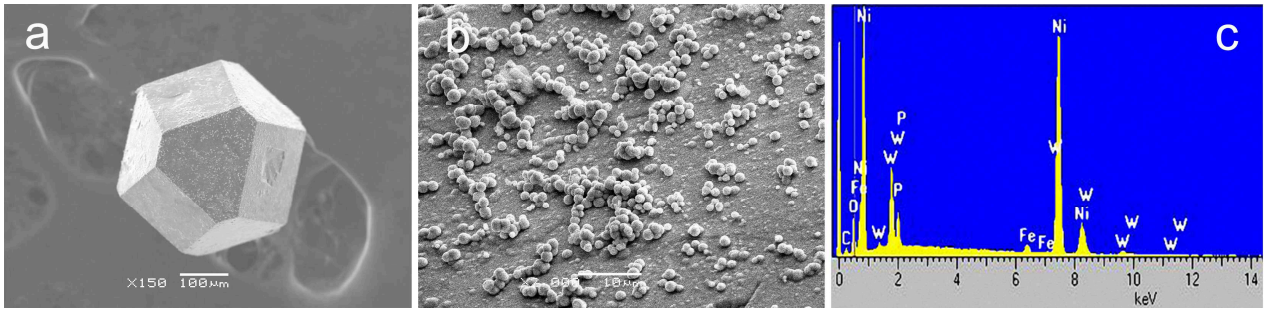

Fig.2 Surface morphologies and EDS of electroless plating Ni-W-P of diamond:
(a) surface morphology, (b) micro-morphology, and (c) EDS.

Hydrothermal Coating Surface Morphology and Composition Analysis

Fig.3 shows particle morphology at different hydrothermal temperatures. The coating on diamond surface at 120℃ is relatively complete and fully coated diamond particles, which surface are formation, uniform, dense and rarely shedding. The diamond surface coating sheds in varying degree at the other temperatures, of which shedding coating is the most serious at about 110℃. Therefore, diamond particles which treated at 120℃ by the hydrothermal method take as the main research object.

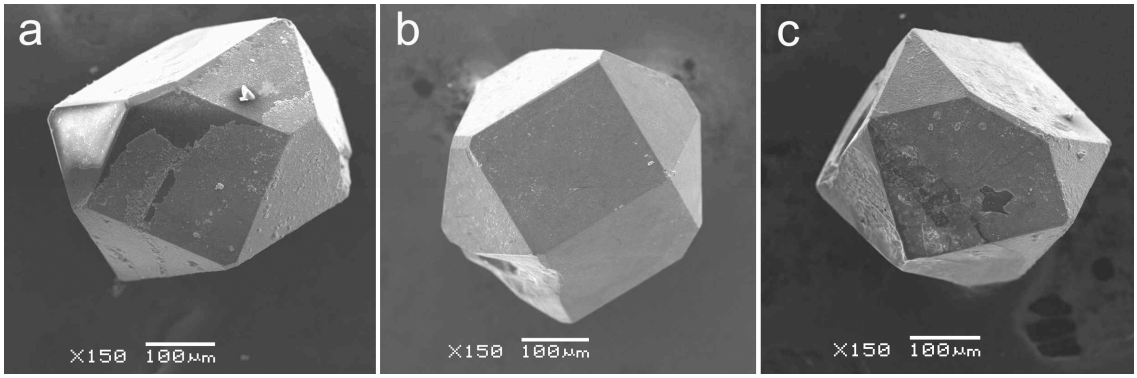

Fig.3 Surface morphology of hydrothermal of diamond at different temperatures.
(a)110℃, (b) 120℃, (c) 130℃

The Coating Surface Morphology after Heat Treatment and XRD Analysis

Fig.4(a) shows the particle morphology and the micromorphology of the coating diagram respectively after surface plating and heat treatment at 850℃. The coatings cauterize to form a large or small cellular layer at a high temperature. The coating surface is rough but more dense comparing with that before heat treatment. Fig.4(b) points out the thickness of coating after electroless plating, hydrothermal duplex plating and heat treatment is about 5-10 μm. The sediment particles formed a dense coating, and the coatings of electroless plating and hydrothermal method have mixed up after heat treatment. However, the internal layer can keep completely in order that the carbide forming elements have enough time to react with the diamond, and this will reduce the oxidation tendency.

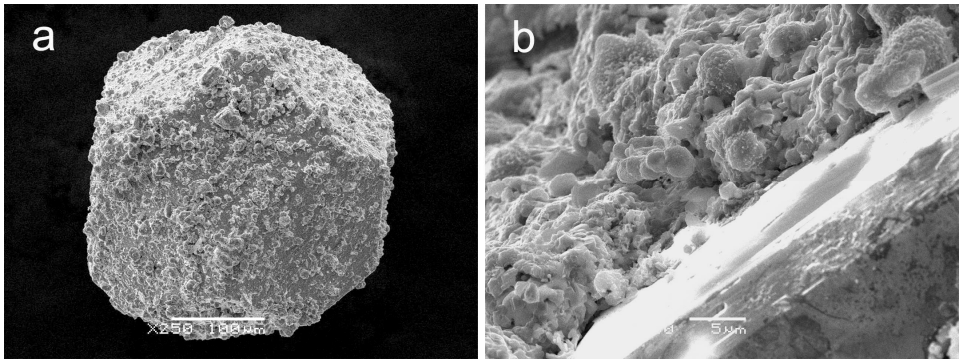

Fig.4 Surface morphology of diamond after plating and heat treatment at 850℃

(a) Diamond particle morphology, and (b) The cross-section morphology of the coating.

XRD analysis can be seen (Fig.5) that the WC and TiC diffraction peaks lines are more sharply after heat treatment. With the temperature raising, the diffusing of W and Ti from high concentration to be low in coating produces. It proves that the carbide WC and TiC created by carbon on the diamond surface and metal W, Ti after heat treatment, and increase binding force between diamond and the coating.

Determination of Compressive Strength

It can be seen from Fig.6 that the compressive strength of diamond improves with temperature increasing. It is because that the boundaries of each solution increased and the rate of coating improves. When the deposition amont of elements increases, the thickness of coating layer will increase. It makes the compressive strength increase similarly. However, when the temperature is 130℃, the Ni compound layer on the reactor's wall would be difficult to clean, and the coating easily shatters. So the compressive strength would decrease. Therefore, the hydrothermal coating temperature should select for 120℃. The carbide forming elements diffuse to the diamond surface under thermal stress between the coating and the diamond after hydrothermal and heat treatment, and the strengthening, hardening and toughening produces at the location area of join parts enhances. That makes the compressive strength increased. The carbide WC and TiC formed with carbon on diamond and carbide forming elements in coating can create greater binding strength and improve the compressive strength of diamond. The compressive strength of hydrothermal treatment at 120℃ is 755MPa, while that after plating and heat treatment is 907MPa. Compared with original uncoated particles, the compressive strength of them can improved to 54.40% and 85.48%, respectively.

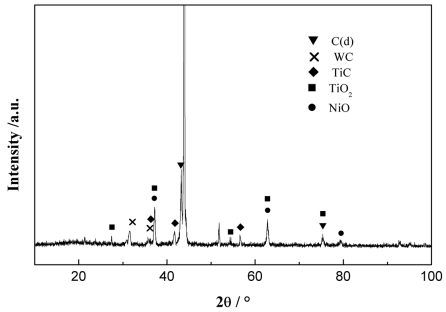

Fig.5 XRD pattern of diamond after plating and heat treatment at 850℃.

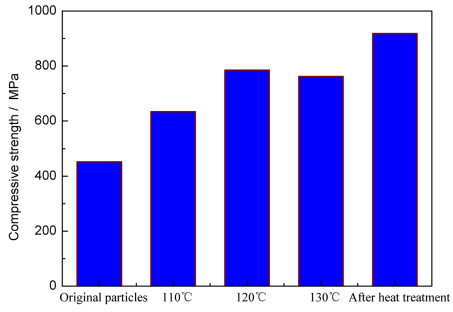

Fig.6 The comparison of compressive strength of diamond.

Conclusion

According to discuss experimental results, the following results are summarized:

(1) The reasonable process of electroless plating and hydrothermal method on diamond surface was studied. The metal coatings on diamond surface which are an uniform, dense and containing Ni, W, Ti after a certain technological, have been gained.

(2) The morphology of coating after hydrothermal at 120℃ for 6h and heat treatment at 850℃ for 1h which is dense and complete was observed by SEM. Such structure is helpful to combing between diamond and coating, and oxidation tendency decreases.

(3) Carbides WC and TiC in coating after hydrothermal and heat treatment were tested by XRD. This can improves the binding force between the diamond and coating, and the chemical combination of diamond has realized.

(4) After hydrothermal and heat treatment, the compressive strength of diamond can be increased. Comparing with the original diamond, the compressive strength of diamond at 120℃ increase to 54.40%, and while that after hydrothermal and heat treatment increases to 85.48 %.

Abstract: The filling and solidification process of casting that is closely related to lots of casting defects and has significant effect on the mechanical properties of castings. In this paper, the research status and development direction of numerical simulation technology of casting, especially of lost foam casting were reviewed and discussed. Also a brief introduction of the basic situations and product characteristics of several outstanding cast filling and solidification simulation softwares were summarized. In addition, the actual domestic application status of numerical simulation technology of lost foam casting in the foundry enterprises was analyzed and some suggestions were given as well.

Introduction

In the LFC process, liquid metal is poured directly onto a refractory-coated, foamed polymer pattern which is buried in loose sand, the polymer pattern undergoes thermal degradation and is gradually replaced by the molten metal, which solidifies and produces the casting. Compared with the traditional way of casting, LFC is more green and efficient, its advantages are as follows [1]: (1) High quality of the castings, particularly for the complicated parts. (2) The flexible design. (3) The clean processing. (4) The low cost of investment. LFC has been very successful in areas such as automobile manufacturing and is widely applied to cast iron and cast steel, but the development of LFC of AI alloy and Mg alloy was relatively slower [2]. The application prospect of LFC will be more extensive as the technology continues to be more mature and innovative.

Due to the gasification of the foam pattern and the gas's interaction with the molten metal, the filling process of LFC is quite complex and very different from the traditional casting in flow field, temperature field, filling capacity, etc. Although it has many advantages, casting defect is more easily generated in the LFC process, thus its further development is cramped. The filling and solidification process can be studied qualitatively and semi quantitatively by computer numerical simulation technology without restriction on the experimental condition, various influencing factors of the casting defect can be found and analyzed, it is significant to both the development of LFC process theory and the guidance of practical production [3, 4, 5].

Numerical simulation technology of casting

A two-dimensional fluid flow software MAC was applied to the filling process of casting for the very first time by R.A.Stoehr et al. in 1983 [6]. Fruitful developments in model description, algorithm optimization, experimental verification and the development of simulation software of

numerical simulation technology of casting which were mainly conducted by American, European, Japanese research workers were witnessed soon afterwards[7, 8, 9]. The tenth International Conference on Modeling of Casting, Welding and Advanced Solidification Processes was held at Destin city of Florida, United States in 2003, the progress in numerical modeling of solidification was briefly reviewed on structure simulation, segregation & microporosity simulation, shaped casting simulation, database and critical experiments[10]. Plenty of studies focused on alloy materials simulation and even some experimental investigations of the flow in continuous-casting mold under the influence of the magnetic field in recent years [11, 12, 13]. Domestic development of numerical simulation of casting is relatively slower, still some important work have been conducted, such as a mathematical model was developed for simulating the fluid flow and heat transfer phenomena during mold filling for die casting using the finite difference method by several scholars at Tsinghua University[14].

Numerical simulation technology of LFC

Numerical simulation technology had been applied to the filling and solidification process of LFC for the prediction of casting defect by Wang et al. in 1993[11]. Abundant research findings of numerical simulation technology of casting have been gradually applied to LFC because of its numerous advantages compared to the traditional way of casting though the craft process is far more complicated. The general flow chart of numerical simulation of LFC is shown in figure 1: (1) The establishment of a reasonable 3-D model of the castings. (2) Generating 2-D and 3-D finite element meshes of the model. (3) Check the grid. (4) Set the corresponding simulation parameters if the meshes are proper, or rezoning the meshes. (5) Simulation calculation. (6) Analyzing the simulation results. The mainly influencing factors of filling and solidification process of LFC are given in figure 2: (1) The gas evolution and chemical reaction of different density of the foam pattern materials are diverse. (2) The air permeability and strength of the coating is vital. (3) The quality of the castings would be affected by different pouring way, sprue-runner-gate area ratio, pouring rate and pouring temperature. (4) Also the vacuum degree, the breathability of the molding sand and the molten metal material are crucial.

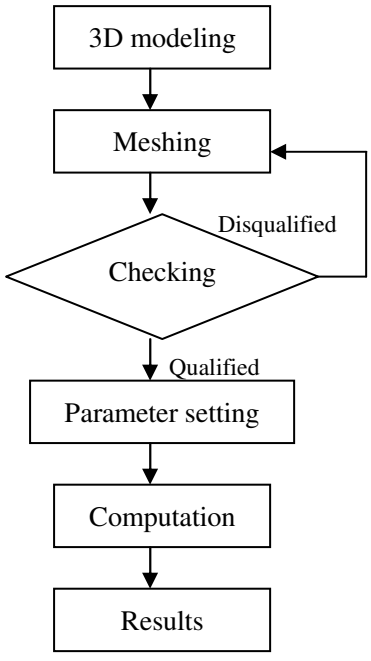

Fig. 1 Simulation flow chart

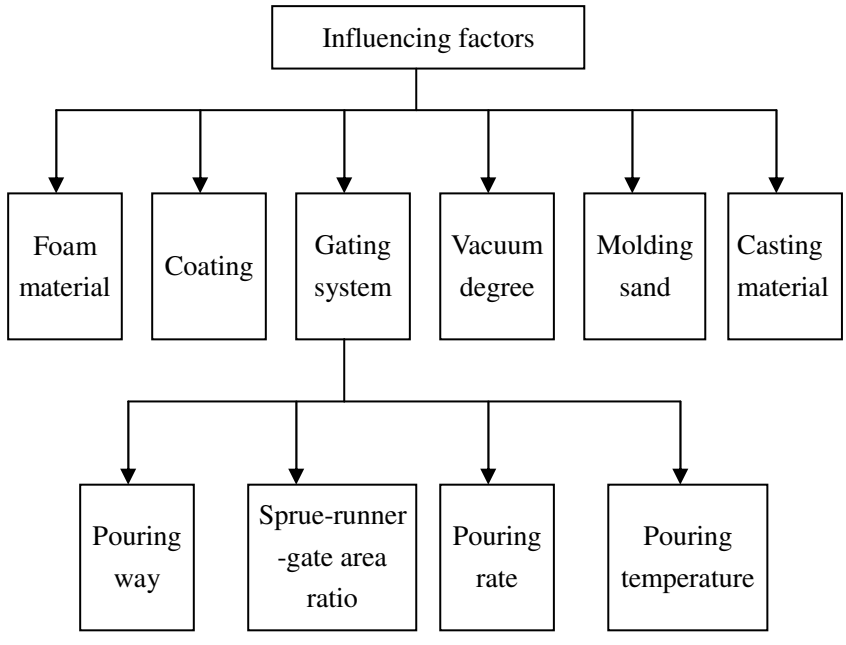

Fig. 2 Influencing factors of LFC simulation

The fundamental key points of an effective numerical simulation of LFC are as follows: (1) The establishment of a reasonable 3-D model, the mesh division and the data transmission problem between them must be solved properly. (2) Lucubrate the mathematical and physical model of the simulation software. (3) Having adequate craft knowledge of LFC. As shown in table 1, these are some major soft wares that have been widely adopted by foundry enterprises of different countries, they have achieved significant economic benefits especially in the western countries. Filling and solidification simulation, residual stress and deformation analyzing can be done by almost all of these softwares though each of them has their own features and focuses. Even some of them can make a predictive analysis of the casting defect and the mechanical performance of the castings and the microstructure analysis is the development direction.

Table 1 Major simulation softwares of different countries

Name	Country	Arithmetic	Main Function	Application
Flow 3D	USA	FVM/FDM	Automatic mesh division; Solidification shrinkage; Binary segregation; Surface defects tracking; Microstructure analysis	Sand mould casting; Die-casting; LFC; Centrifugal casting; Continuous casting
MAGMA Soft	Germany	FDM/FEM	Analysis of flow and heat transfer, stress and microstructure; Strong pre processing and post processing functions	Sand mold casting; Shell mold casting; Pressure casting; Investment casting; Metal mould casting
Procast	France	FEM	Free surface flow, stress and deformation calculation; Simulation of the microstructure formation	Sand mold casting; Shell mold casting; Low pressure permanent casting; LFC; Investment casting; Centrifugal casting
ADSTEFAN	Japan	FEM	Large mesh model; Predict shrinkage, thixomolding, defects, temperature; Stress and structural deformation calculation	Pressure casting; Sand mold casting; Thixomolding casting
InteCAST	China	FDM	Flow mold filling & solidification process; Mold filling heat transfer coupling	Sand mold casting; Shell mold casting; Pressure casting; Investment casting; Metal mould casting

Lots of foreign scholars focused on the establishment of the mathematical model of the LFC process in recent years. A computational fluid dynamics model has been developed by S.H. Bhavnani et al. to simulate the fluid flow of molten aluminum and the heat transfer involved at the interfacial gap between the metal and the foam pattern [15].A 2D model was developed by J. Shayegh et al. for heat transfer, foam degradation and gas diffusion at the interfaces of the liquid metal, foam pattern and gaseous gap in between, for EPS lost foam casting process [16]. Appropriate physical and kinetic models of thermal degradation of EPS foam applicable to LFC were reviewed by Pravin Kannan et al [17].

Domestically, the hydrodynamics characteristic of foam degradation of LFC was studied by Z.L. Zhang et al. and they also predicted the remnants of the foam pattern and its impact to the casting quality [18]. How different alloy materials, pouring system affect the filling and solidification process of LFC and how to choose the optimum casting parameters were given by J.H. Zhao by using Procast [19]. Y.L. Ma proposed to optimize craft from the perspective of defect prediction and

the analyzing of the causes of the formation of the defects [20].On the basis of production experience, the characteristics of LFC and the actual production conditions, X.SH. Li designed a kind of LFC craft of connecting cylinder and the causes of foundry defects were analyzed [21]. J. Peng researched the variations in vacuum degree during the filling process of LFC and analyzed the wall attachment effect and the gas trapping and regurgitating process [22]. Also numerical simulation for filling process of EPS beads in LFC is one of the hotspots [23].

Domestic application Status

Table 2 Domestic application status of numerical simulation technology of LFC

Actuality	Major cause	Suggestions
1. Perfunctory with the customer 2. Popularisation means 3. Good earning performance	1. Technological base is poor 2. Lack of consciousness in application of new techniques 3. Improper use of the technology 4. The limitations of the software itself	1. Change some technicists's backward perception 2. Enhance training specialized talents 3. Having a correct view of the technology and utilize it rationally

Numerical simulation technology of casting is having a widespread use in the western countries, particularly almost all of the car castings manufacturers are equipped with simulation system, but the popularization rate of numerical simulation technology of LFC of our country is very low, of course there are some but rare enterprises which have successfully applied this technology and have a good earning performance. The domestic application status is shown in table 2, since small and medium-sized enterprises dominate the domestic LFC industry, the technological base is poor and even some senior technicists thought that problems could be solved based on their experience.

Conclusions and Outlook

The numerical simulation of filling and solidification process, stress and microstructure analysis of solidification process, the prediction of shrinkage cavity and porosity are the main current research and application fields. Because of the coexistent of liquid and solid metal, the mechanical property of the castings is hard to measure during the simulation process and still the proper mechanical model can't be completely established. The simulation of microstructure is far more complicated than the filling and solidification process, whereas the simulation technological conditions are generally set in a too simplistic and idealized way, besides, the scale of majority domestic foundry enterprises are small, the production equipment is lag behind and the technical strength is weak, it is difficult for them to provide the rigorous actual production process conditions and the technicians are lack of systematic professional training, thus domestically there is still some way to go to apply this technology to the actual production efficiently and broadly.

Keywords: cutting parameters; NSGA-II; optimization

Abstract: In this paper, we take the CNC milling on as the object of the research and establish an optimized model of cutting parameters by using algorithms based on NSGA-II. Taking the machining time and the surface roughness as target function, and the rotational speed and cutting power as constraint condition, the optimization of a CNC milling case is realized, and is verified by simulation of cutting using CAXA ME and Vericut. The outcome confirms the truth that NSGA-II is a useful technique in the optimization of cutting parameters.

Introduction

Choosing cutting parameters is one of the most important steps in a machining process. Using appropriate cutting parameters is the guarantee of machining quality, it also lowers the production cost and increases the productivity in a machining process [1]. However, choosing cutting parameters is constrained by many factors among which there exists interaction and restriction with each other. The core problem to be solved in the optimization of machining process is to make an appropriate choice of cutting parameters and find the optimum combination of them.

Genetic algorithms have been applied in optimization of machining process, but they have their disadvantages respectively. In reference [2] there is only one production target considered, while although in reference [3] and reference [4] multiple goals are taken into consideration, we have to set weight for different production targets, which is subjective and lacks of flexibility when responding to changes in actual production, because we can't decide the weight of one production target when unknown variant involves and production changes.

MOGA (multiple-objective genetic algorithms), which evolves from GA, has been focused on methods based on Pareto-optimal in recent years [5]. Research on MOGA has produced SPEA (strength-Pareto evolutionary algorithm), PAES (Pareto-archived evolutionary strategy), NSGA-II (non-dominated sorting genetic algorithms II), etc. NSGA-II, one of the mature algorithm of MOGA, approaches the Pareto-optimal front by using a fast non-dominated sorting approach [6] and presents a new selection operator. The NSGA-II has also been widely studied because of its good performance in multi-objective optimization.

In this paper, we build an optimized mathematical model, using t_w (machining time of each work piece) and Ra (surface roughness) as the optimization target, v_c (milling speed), f (feed rate), a_p

(milling depth) and a_e (milling width) as design variables, and spindle rotation speed and cutting power as the constraint condition. By using NSGA-II, we make a pilot study of applying this method to optimize machining process and attempt to get an optimal set of values when the condition of multiple production targets are considered and give relative quantitative production targets values, which is for technologists' reference in production practice.

NSGA-II

Introduction to NSGA-II

Non-dominated sorting genetic algorithm, which was first proposed by Srinivas and Deb in 1994, is a multi-objective genetic algorithm based on Pareto-optimal. It's flexible in choosing the number of objectivities to be optimized and can give the non-inferior solution which is even distributed, hence in the field of multi-objective optimization it shows strong superiority. However the defects emerges as deeper researches are taken, mainly in the following three aspects: a) computational complexity, b) elitism approach is lacking, c) the need for specifying a sharing parameter. Against these defects, Deb improved the core algorithm in NSGA [7], as well as introduced elitism approach and computation for congestion degree, which alleviated all the three difficulties mentioned above.

As experiment already presented [8], NSGA-II shows a better functionality in contrast with other representative algorithms like PAES, SPEA, etc.

The non-dominated sorting algorithm is shown in Fig. 1:

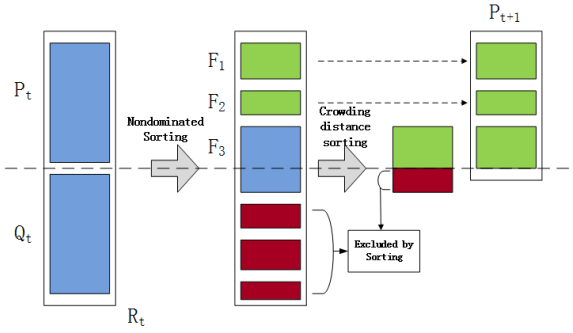

Fig. 1. Non-dominated Sorting

Calculation Process of NSGA-II

The calculation process of Non-dominated Sorting Genetic Algorithm based on Pareto solution can be described as follow (also shown in Fig.3):

(a). Randomly generate the initial parents population P_0 with population size N;

(b). Apply non-dominated sorting on population P_0, assign adapted value for each individual correspondingly;

(c). Manipulate P_n using genetic operators (selection, intersection, variation) to get population Q_n;

(d). Get a synthetic population R_n of size $2N$ which composes of parents population P_n and offspring population Q_n, apply non-dominated quick sorting, delaminate R_n anew through non-dominated hierarchy and get hierarchy F_1, F_2, F_3 ……;

(e). Empty P_n and put F_1, F_2, F_3……in P_{n+1} seriatim until the number of elements in $\{P_{n+1} + F_t\}$ is bigger than N and the individual number of P_{n+1} is less than N;

(f). Compute the crowding degree of hierarchy F_t and sort on it, put the first $N - |P_{n+1}|$ individuals in P_{n+1}.Now the individual number of P_{n+1} is N;

Repeat step (c) to step (f) until the iteration stops.

The whole process is shown in Fig.2 as follows.

Mathematical Model of Optimization in Machining Process

Multi-objective Optimization

Problems on multi-objective optimization can be described in a mathematical model as Eq.1, Eq.2 and Eq.3.

$$\text{Design variables: } X = [x_1, \ldots, x_n]^T \tag{1}$$

$$\text{Target Functions: } f(X) = [f_1(X), f_2(X), \ldots, f_n(X)] \tag{2}$$

$$\text{Constraint conditions: } \begin{matrix} g_i(X) \geq 0 (i = 1, 2, \ldots, n) \\ h_i(X) = 0 (i = 1, 2, \ldots, n) \end{matrix} \tag{1}$$

Target functions described above are always optimization targets which conflict with each other. Optimization of each target function maybe either maximum or minimum. But since transformation between them can be realized, we can take minimum as the optimization target of each function uniformly.

In this paper, we consider minimum as the optimization target.

Design Variables

We reference the four elements of milling dosage [9] as design variables, which includes: milling speed v_c, feed rate f, milling depth a_p, milling width a_e.

The relation between milling dosage and related parameters are:

$$v_c = nD\pi / 100 \tag{2}$$

$$v_f = fn = f_z zn \tag{3}$$

In above equations Eq.4 and Eq.5, n is milling speed, D is cutter diameter, f_z is feed rate per tooth, and v_f is feed speed.

Objective Functions

In production practice, the following objective functions are in common use: maximum production rate, the minimum production cost, the maximum profit rate, metal removal rate and surface roughness. Here we use the maximum production rate (the shortest time to produce a singleton) and the minimum surface roughness as our objective functions.

Production Time Function

Referring to MINFRE, the method to calculate time of machining a singleton [10, 11] is:

$$t_w = t_m + t_c \frac{t_m}{T} + t_0 \tag{4}$$

$$T = \left(\frac{C_v d_0 q_v}{v_c a_p^{x_v} f_z^{y_v} a_e^{u_v} z^{p_v}} \right)^{\frac{1}{m}} \tag{5}$$

In above equations Eq.6 and Eq.7, t_w is time of machining a singleton, t_m is cutting time of a single process, t_c is tool change time, T is tool life, t_0 is auxiliary time besides tool change time; and $C_v, q_v, x_v, y_v, u_v, p_v, m$ are correlation coefficients related to tool life T, which are bound up with cutting parameters and cutting conditions.

Surface Roughness

The calculation of surface roughness [10] is:

$$Ra = 318 \frac{f_z^2}{4 d_0} \tag{6}$$

In the above equation Eq.8, f_z is feed rate per tooth and d_0 is cutter diameter.

Constraint Conditions

Machine Tool Speed Constraint

Constrained by machine tools, the rotating speed must be controlled within the limits of spindle speed

$$v_{\min} \le v \le v_{\max} \tag{7}$$

In the above equation Eq.9, $V_{\min}$ is the minimum spindle speed while $V_{\max}$ is the maximum.

Machine Tool Power Constraint

The actual cutting power P_m is supposed to be less than the product of rated power P_E and total efficiency η, that is [10]

$$P_m \le P_E \bullet \eta \tag{8}$$

$$P_m = \frac{F_c \bullet v}{1000} (kw) \tag{9}$$

$$F_c = C_{F_c} a_p^{x_{F_c}} f_z^{y_{F_c}} a_e^{z_{F_c}} d_0^{m_{F_c}} Z n^{p_{F_c}} K_{F_c} (N) \tag{10}$$

In the above equations Eq.10, Eq.11, Eq.12, F_c is main cutting force, C_{F_c} is influence coefficient which is related to experiment conditions; $x_{F_c}, y_{F_c}, z_{F_c}, m_{F_c}, n_{F_c}$ are impact indexes on

cutting force; d_0 is cutter diameter, Z is the number of cutter teeth and K_{F_c} is the correction factor of cutting force when calculation conditions are different from experimental conditions.

Other Machine Tool Constraint

In actual production, the choose of cutting dosage is limited by the constraint of machine tool system, it need to satisfy the following conditions shown as Eq.10 and Eq.11:

$$f_{\min} \le f \le f_{\max} \tag{11}$$

$$a_{p\min} \le a_p \le a_{p\max} \tag{12}$$

Cutting Experiment Simulation

Experiment Process

a). Consult with the manual to get each coefficient and a recommended range of cutting dosage for reference; b). Implement the NSGA-II through programming language, input each parameters and get a set of optimum values after computing; c). Establish the geometry model and generate NC machining code in CAXA ME; d). Operate the simulative cutting test in Vericut and analyze the experimental results we get.

Machining Environment

The size of machining part: 230*120*35, mm as its unit of measurement (which is illustrated by Fig. 4).

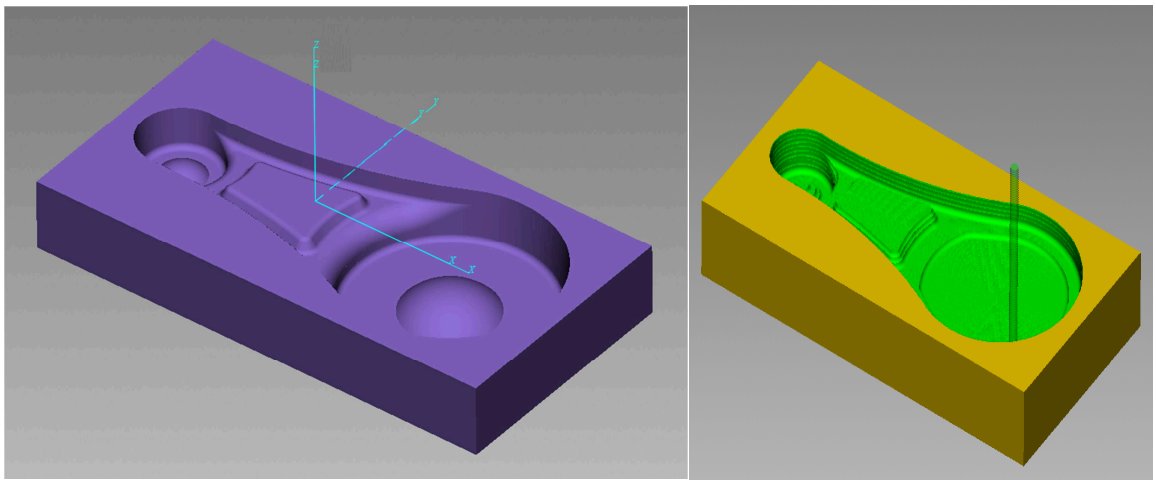

Fig. 4. Part design and machine Simulation

Material of machining part: carbon structural steel, σ_b=650MPa.

Machining tool: ball end cutter with diameter 10mm and material cemented carbide.

Table 1 shows the type of machine tool for use: XK5032, consulting with manual for relevant information [12].

TABLE 1.MACHINING TOOL INFORMATION

Type	Machine size(mm)	Table travel (mm)	Spindle speed (r/min)	Main electric power(kw)
XK5032	320×1120	760×350×400	80~4500	5.5

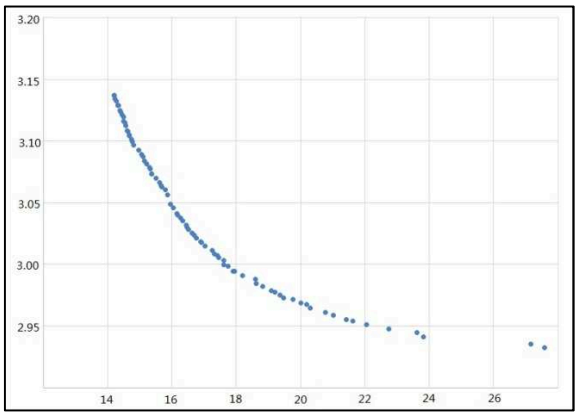

Fig. 5. Computation result

Experimental results

By applying the non-dominated sorting in the calculation process of NSGA-II, we eventually get the datum which belongs to the same non-sorting degree after calculation. The distribution of the outcome shown in Fig.5 can be considered as the Pareto front of the calculation.

In the following table we choose a set of datum in the medium of the result as optimized parameters to compare with empirical parameters:

TABLE 2. EXPERIMENTAL RESULTS

Parameters	n(r/min)	v_f (m/min)	a_p (mm)	a_e (mm)	Ra (μm)	t_w (s)
Empirical parameter[9]	1900	0.95	3	3	3.15	23.57
Optimized parameter	2763	1.10	3	3	3.01	17.13

From the experimental results shown in Table 2, we come to the conclusion that after we use the optimized cutting parameters not only has the surface quality been improved but also the machining time reduces substantially. Hence we draw the conclusion that this algorithm is effective in optimizing cutting parameters. Referring to related theories of metal-cutting, a higher cutting speed can produce a better surface, which proves the correctness of the result in another aspect.

Conclusion

In this paper we introduce the NSGA-II algorithm into cutting parameters optimization. Optimize the cutting dosage by establishing optimal mathematical model and realize the optimization by programming language. Then we validate the optimized results using CAXA ME, generating the NC code, and Vericut, simulating the machining process. By the verification and analysis of the simulative machining results, we could draw the conclusion that the algorithm we have used in this paper can meet the demand for parameters optimization and it can be valuable when applied in engineering.

Keywords: microwave heating; 316 stainless steel; heating behavior

Abstract. This paper mainly introduces the mechanism of microwave heating: electric conduction loss, eddy current loss and arc discharge. The microwave heating behavior of 316 stainless steel powder body which made by gel casting was investigated in the paper. Experiments on different microwave power, powder particle size, and the content of auxiliary heating material showed that the smaller the powder particle size, the larger microwave power and auxiliary heating materials help 316 stainless steel body for sintering.

Introduction

Microwave sintering began in the 1960s when Tinga. W. R [1] proposed the microwave sintering of ceramics materials. The microwave sintering of metal materials was proposed 30 years later. Metals do not absorb microwaves and reflect it totally in the traditional view, until the Professor R. Roy [2] proved that stainless steel, copper alloy, nickel base alloy powder parts can be sintered by microwave heating. The report caused the wide attention of microwave sintering of metals. Then, K. Saito [3] sintered Fe, Co, Ni, Cu and stainless steel powder compact successfully by microwave sintering, and found that microwave can promotes sintering process except Fe. A. Upadhyaya [4] et al using both conventional sintering and microwave sintering way to sintered 316L stainless steel and 434L stainless steel powder compacts, and found that heating rate reached 45℃/min, the sintering time reduced by 90% by using microwave sintering.

In China, microwave sintering technology was proposed by Wuhan University of Technology in 1988. Then comes to Shenyang Metal Research Institute of Chinese academy of sciences, Shanghai Silicate Research Institute of Chinese academy of sciences, Tsinghua University [5]. Huang [6] analyzed the theory model of microwave heating mechanism, proposed the calculation method of absorbing properties. Peng [7] studied the heating properties of metal powder compact with different elements, different compacting pressure and different output power, and drew a conclusion: the temperature curve of microwave heating is a function of metal powder particle size. The smaller the particle size, the faster the heating rate and the higher the heating temperature obtained. Heating rate depends on the porosity of metal powder compact. Under the same power output, the higher the porosity gets faster heating rate, while the temperature eventually achieved has nothing to do with the initial porosity. Zhou [8] used the microwave sintering sintered WC-Co alloy, found that magnetic loss dominates in low temperature area (below 1100℃), while in high temperature (above 1100℃), Co changes from ferromagnetism to paramagnetism with the collapse of the magnetic domain. The magnetic contribution to the energy dissipation is very weak, WC-10Co alloy absorbs microwave energy mainly in the form of dielectric loss.

Microwave heating technology, with its unique advantages in metallic materials applications, has broad prospects. In this paper, the characteristics of microwave heating 316 stainless steel(316SS) is studied with a series of experiments, and microwave sintering process of 316SS are discussed.

Microwave Heating Mechanism of Powdered-metal Body

When a metallic metal conductor in the electromagnetic field, its internal free charge will quickly gather to the surface under the effect of electromagnetic field. Relaxation time is used to characterize the speed of free charge response to electromagnetic field change. It is far shorter than

electromagnetic vibration period, so in the beginning of every vibration cycle, free charges had already gathered on the conductor surface, and internal free charge density is zero. Since there is no free charge inside the bulk metal, bulk metal cannot be effectively heated. Electric current exists on the surface of the metal conductor within the electromagnetic field, which results ohmic losses. Decreasing the size of metal conductor, to make it exactly couple with microwave electromagnetic field, causes effectively heating [9 ~ 11].

The mechanism of interaction between microwave and material are free charge movement loss, bound charge polarization loss and non-uniform interface loss [12 ~ 13]. For powdered-metal body, Yi [6] considered that the dielectric loss, the eddy current loss and powder particles of microwave multiple scattering lead to energy transformation. In the process of sintering microwave energy will be converted to heat energy.

Conductance Loss

Interaction between electromagnetic wave and material varies with wavelength, microwave mainly affects the rotation of the free molecule and bound molecule. The mechanism of interaction between microwave and materials is closely related to the external electromagnetic field, and it can be described using Maxwell's equations.

For nonmagnetic material, the microwave propagation law in the material submits to the differential forms of Maxwell's equations. The power absorbed per unit area of the conductive surface, P, is expressed as

$$P = \frac{R_s}{2}\int_v |H_t|\,\mathrm{d}V = \frac{2R_s|E_0|^2}{\eta_0^2} \tag{1}$$

Where Rs is the surface resistivity ($Rs = 1/\delta\sigma$, σ is electrical conductivity, and δ is the skin depth); E_0 is the electric field amplitude at the surface; and η_0 is the impedance of free space (377Ω). Assuming the radius of spherical metal powder particle is r_p, the electromagnetic power density (PEM) can be expressed as

$$P_{EM} = \frac{3P}{r_p} = \frac{6R_s|E_0|^2}{\eta_0^2 \cdot r_p} \tag{2}$$

If all the microwave energy is converted into heat energy, the change of temperature can be expressed as

$$\frac{\Delta T}{\Delta t} = \frac{P_{EM}}{\rho C_p} = \frac{6R_s|E_0|^2}{\eta_0^2 r_p \rho C_p} \tag{3}$$

Where T is the temperature; t is the time; ρ is the density of powder; and C_p is the specific heat capacity.

Eddy-current Loss

Initially, particles are loose contact in the green body, electric contact and heat transfer are very weak. When the green body is put in the microwave field, electrons on the metal surface move directionally under the effect of microwave electromagnetic field, which produce the so-called eddy current [16].

The eddy-current loss is one of the microwave sintering mechanisms of powdered-metal [11, 14]. Free charges in metal conductor have a very fast speed under the effect of electric field force. Relaxation time is 1e(-18)s orders of magnitude, while microwave vibration period is between 1e(12)~1e(9)s. There is a great difference between them. It is assumed that microwaves' component of electric and magnetic field are constants to the movement of free charge, which means microwave can be described as the uniform plane wave which is a simple superposition of orthogonal

electrostatic field and static magnetic field. Before charges move to the surface of the particle, the particle is not an equipotential body, it still exists the electric field intensity (E_x) inside. As shown in Fig. 1, motion electron is forced by electric field force (F_E) and Lorentz force (F_B) at the same time, their circular motion in plane OXZ forms eddy current. If lower the intensity of electric field and magnetic field, the induced current could not breakdown the particle interface with certain resistance, free electrons are bound in the respective of particles, no accumulation of charge on the surface. There are eddy current inside each particle, and produce joule heat, thus heating the body as a whole.

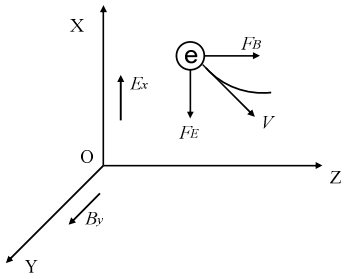

Fig. 1. The Movement of Free Electron in the Metal Particles in Microwave Field

Arc Discharge

Arc discharge also makes contribution to the microwave heating. Powered-metal body is porous, there are lots of gaps between particles. The clearance between the powder particles produce arc discharge in the microwave field, so as to heating the body. Residual gas in the body fuelled the arc discharge phenomenon. Arc discharge was promoted by increasing the microwave power. On one hand, it is propitious to promote the sintering, on the other hand, too much of arc discharge will lead to "thermal runaway", and there will be a larger reflected power into the magnetron, reduce the service life of magnetron.

Experiment

Powders used in the experiments were gas-atomized 316(C: 0.053; Si: 0.611; Mn: 0.757; Ni: 10.49; Cr: 17.99; Mo: 2.197; S: 0.0085; P: 0.033; and Fe: bal.) stainless steel (Shandong Zhongtai alloy co., LTD.). The mean particle size is 12.71μm. Powders were graded to four levels (<25μm, 25~38μm, 38~50μm, >50μm) according to size by using vibration test sieve.

Green bodies were obtained by gel casting; gelatin was selected as binder, sodium alginate as dispersant. A slurry made from metal powder and a water-based monomer solution is poured into a mold, polymerized in-situ to immobilize the particles in a gelled part, removed from the mold while still wet, then dried. Green bodies were heated in a vacuum tube furnace (Yixing Qianjin Furnace Industry Equipment Co., Ltd., KTF1400) to eliminate moisture at 600℃. The body is about 8g. Microwave vacuum sintering furnace (Changsha Synotherm co., LTD., HAMiLab - HV3) with a frequency of 2.45GHz was used for Microwave sintering. Bodies were placed in a quartz crucible, alumina was selected as thermal insulation material, and silicon carbide as auxiliary heating material. The temperature of specimen was measured using an infrared pyrometer (American Raytek MM2MH). The heating equipment is shown in Fig. 2.

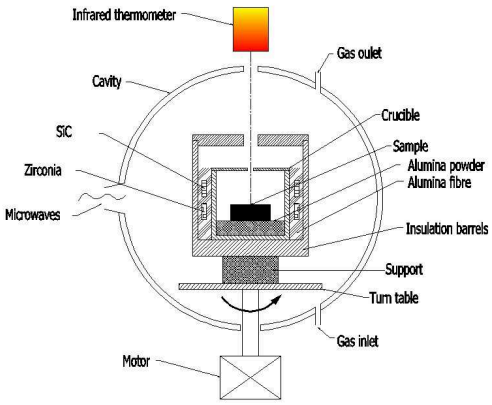

Fig. 2. Microwave Heating Experiment Device

Parametric Comparative Experiments and Discussion

As compare to conventional sintering, microwave sintering is expected to be more uniform and energy-saving. The microwave heating behavior is influenced by many factors, three of them were studied in this paper. Experiments with different microwave power: 600w, 800w, 1000w, and 1200w were carried out on microwave heating characteristics of the gelcast body, and powder size is 0~25μm. Experiments with different powder size: <25μm, 25~38μm, 38~50μm, >50μm under the microwave heating power of 1000w were carried out. Experiments with different content of auxiliary heating materials (SiC): 0g, 25g, 50g, and 100g were performed, and powder size is 0~25μm.

Microwave Heating Power

Microwave power has great effect on the heating behavior of 316SS. As shown in the Fig. 3, the temperature curve can be divided into four stages. In the initial stage, the body temperature rises quickly (300~400℃/min) until to a turning point (600~800℃). This is because the body is the source of heat, it absorbs a lot of microwaves and converts them into heat energy. The second stage: body temperature maintains a balance or decrease, mainly because heat dissipation is more than heat absorption. A lot of heat conduction and radiation, cause the decrease of body temperature. The third stage: heat absorption is greater than the heat dissipation the body temperature rise gradually. Stage 4: when the temperature reaches a certain value, the heating rate decreases, temperature curve flatten out, until the body reach thermal equilibrium, the sintering temperature reach the maximum.

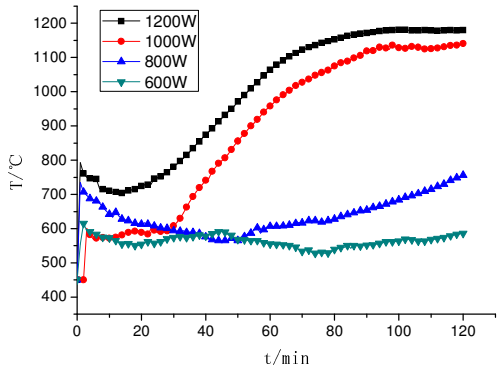

Fig. 3.Thermal Profiles of 316SS Powdered-metal Body as a Function of Microwave Heating Power.

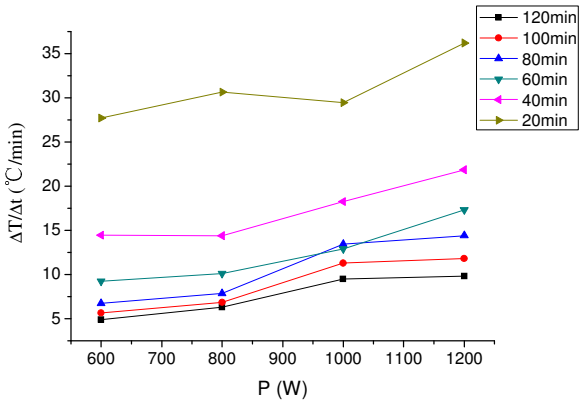

Fig. 4.The Heating Rate of 316SS Powdered-metal Body During the Different Time Period

Fig.4 shows a linear relationship between heating rate and the microwave power approximately. As mentioned in formula (3), $\Delta T/\Delta t$ is in direct proportion to P_{EM}/C_p. When increasing the input power, the power density will increase, so does the heating rate. But too high microwave power has adverse effects on the sintering. First, it may lead to "thermal runaway". Local sample absorbs a large amount of microwaves, then the temperature rises rapidly, resulting in a burnt body and grain

boundary oxidation. Second, higher power means more microwaves, the body cannot absorb all of them, plenty of them are reflected back, not only cause the waste of energy, but also shorten the service life of the magnetron microwave generator.

Powder Particle Size

Fig. 5 shows that bodies with smaller powder particle size have higher heating rate. For 316SS, the magnetic permeability is μ=1.008, resistivity is σ=7.4×10-7Ω·m, and microwave frequency is f = 2.45GHz. According to the penetration depth formula, the penetration depth of 316SS is about 3μm. For spherical powder, those radius less than 3μm undergo volumetric heating when subjected to microwaves. However, for relatively coarse powders (r_p >3μm), the heating may be conductive from the outside (skin) to the interior of the powder. The volume fraction of the coupled zone can be calculated.

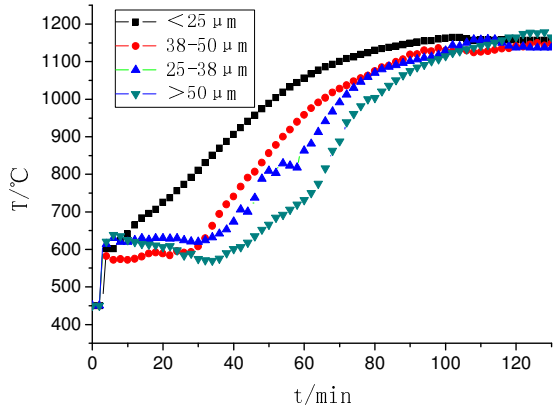

Fig. 5. Thermal Profiles of 316SS Powdered-metal Body as a Function of Particle Size under the Microwave Heating Power of 1000w.

As presented in Fig. 6, assumes that the powder radius is r_p, the penetration depth is δ. The shadow part is the area of interaction with microwaves.

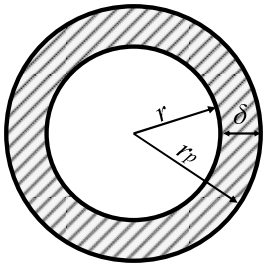

Fig. 6. The Spherical Powder

The volume of powder is

$$V = \frac{4}{3}\pi r_p^{\,3} \tag{4}$$

The interaction volume is

$$V_e = \frac{4}{3}\pi\left(r_p^{\,3} - r^3\right) \tag{5}$$

The interaction volume fraction is

$$\frac{V_e}{V} = \frac{r_p^{\,3} - r^3}{r_p^{\,3}} = \frac{r_p^{\,3} - \left(r_p - \delta\right)^3}{r_p^{\,3}} = 1 - \left(1 - \frac{\delta}{r_p}\right)^3 \tag{6}$$

It indicates that the larger powder size results in the smaller interaction volume fraction. The interaction volume fraction of four powder sizes are calculated in table 1.

TABLE 1. THE INTERACTION VOLUME FRACTION OF DIFFERENT POWDER SIZES.

Powder size	0~25μm	25~38μm	38~50μm	>50μm
Volume fraction	0.56~1	0.40~0.56	0.32~0.40	0~0.32

The Content of Auxiliary Heating Materials

Auxiliary heating materials also have influences on the microwave heating behavior. As presented in Fig. 7, surrounded by SiC, the body obtains lower temperature at first stage. The main reason is that at the beginning of sintering both bodies and SiC absorb microwaves, the body surrounded by SiC absorbs less microwaves. The Fig. also suggests that heating rate and sintering temperature increase with the increase of the SiC content. When the content of SiC reaches a certain value, more SiC have little influence on microwave heating. To compare temperature cure of 50g of SiC and 100g of SiC, they are almost the same.

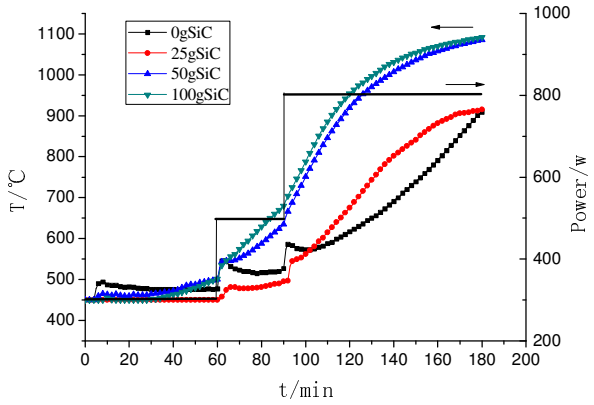

Fig. 7. Thermal Profiles of 316SS Powdered-metal Body as a Function of the Content of SiC.

As shown in Fig. 8 after adding SiC, the body with different powder particle size show the familiar heating properties and their temperature curve almost coincide. Power of 300W, 500W and 800W result in the heating rate of 3℃/min, 5℃/min and 7℃/min respectively. To sum up, SiC help microwave rapid heating, promote the effect of sintering. Both SiC and green body absorb microwaves, the body could be volumetric heating. However, excess SiC is not conducive to the uniformity of temperature field. Excess SiC absorb more microwaves than the body, thus the temperature of the edge of the crucible is higher than the center.

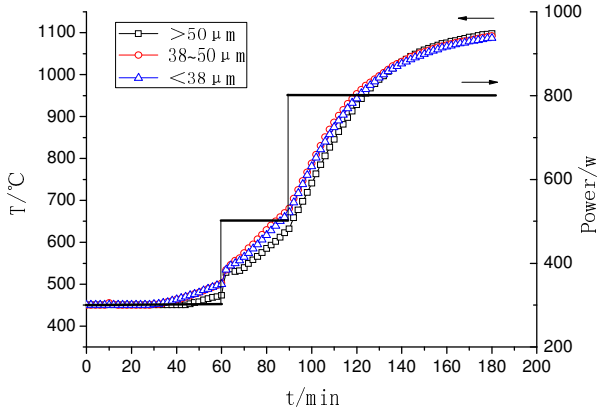

Fig. 8. Thermal Profiles of 316SS Powdered-metal Body as a Function of Particle Size after Adding 50g of SiC.

Conclusions

Experiments on heating of 316SS green bodies in microwave oven with 2.45GHz indicated that 316SS powders with varying mean size can effectively couple with microwaves and be heated to high temperatures. Compare to the conventional sintering, microwave sintering exhibits different remarkably heating behavior. Sintering process is influenced by the microwave power, powder particle size and the thermal insulation installation. The results show that the heating rate is increased by the increase of the microwave power, which approach a linear relationship. The smaller the powder size, the higher the heating rate. The auxiliary heating material (SiC) also has great effect on the heating behavior. It is helpful to achieve fast and uniform heating in green body.

Keywords: A5083-H111 Al alloy; Environment Welding; Temperature; Microstructure; Mechanical Properties

Abstract: In this paper, A5083-H111 aluminum alloy was welded under different environment temperatures. Microstructures and mechanical properties were analyzed. The results show that the grain size of precipitated phase in welded seam deceased and the content increased with the increase of environment temperature. The hardness was the lowest in welded seam. The hardness increased with the distance away from welded centre. The hardness of welding zone of welded joint was generally low below 0 ℃. The strength and toughness were higher at welding temperature above 0℃ than that welded below 0℃. If the welding parameters were well controlled, A5083-H111 Al alloy can be welded at temperature ranging from -20℃ to 40℃ with relative humidity of 50%.

Introduction

With the development of transportation, light weight for transportation vehicles was an important factor to improve train speed. At present, as a light weight material,aluminum alloy was applied more and more widely in high speed train. At the same time, A5083 was one kind of aluminum alloy which was widely used in high speed train. Most of the train structures were connected by welding. Aluminum alloys were generally difficult to fusion weld because mechanical properties can be seriously degraded as a result of heat-induced changes to their precipitate structure and dentritic structures formed during the fusion welding process [1]. The quality of welding joints was not only influenced by welding parameters, but also by the environmental conditions in the process of welding. Welding temperature, humidity and wind speed are all likely to have underestimated influence on the quality of welding joints.

Chen Li [2] et al. researched performance of pipeline steel welding under low temperature of -28 ℃ ~ - 15 ℃. The result showed that the effect of welding temperature on tension strength, surface bending, back bending, slot breaking and hardness was not obvious, while the effect was higher on low temperature impacting stiffness value.

Yang Wu [3] et al. have researched the influence of construction site on thick steel plate welding stress. The results showed that the welding residual stress declined with the increasing of air temperature in construction site. The increasing rate of stress was 6%-32% when temperature decreased per 10 ℃.

Meng Qing li [4] et al. investigated the welding procedure for petroleum-natural gas X65 pipeline steel in 90%-95% humidity environment. The results showed that if joints was good designed and the welding process parameters was made to control heat input during welding, good properties of welding joints can be obtained.

In order to keep the welding quality, factories had to keep the environment at constant temperature and humidity, which leaded to high cost of manufacturing. Thus, A5083-H111 aluminum alloy was welded under different environment temperature in this paper to research effects of environment temperature on the microstructures and mechanical properties.

Experimental Details

Welding process

The A5083-H111 aluminum alloy was used as base metal. The chemical composition of A5083-H111 aluminum alloy was listed in Table 1. The welding wire used was ER5356，whose chemical composition was listed in Table 2.

TABLE 1 CHEMICAL COMPOSITION OF A5083-H111 ALUMINUM ALLOY（WT%）

Element	Si	Fe	Cu	Mn	Mg	Cr	Zn	Ti	Al
A5083-H111	≤0.40	≤0.40	≤0.10	0.40-1.0	4.0-4.9	0.05-0.25	≤0.25	≤0.15	

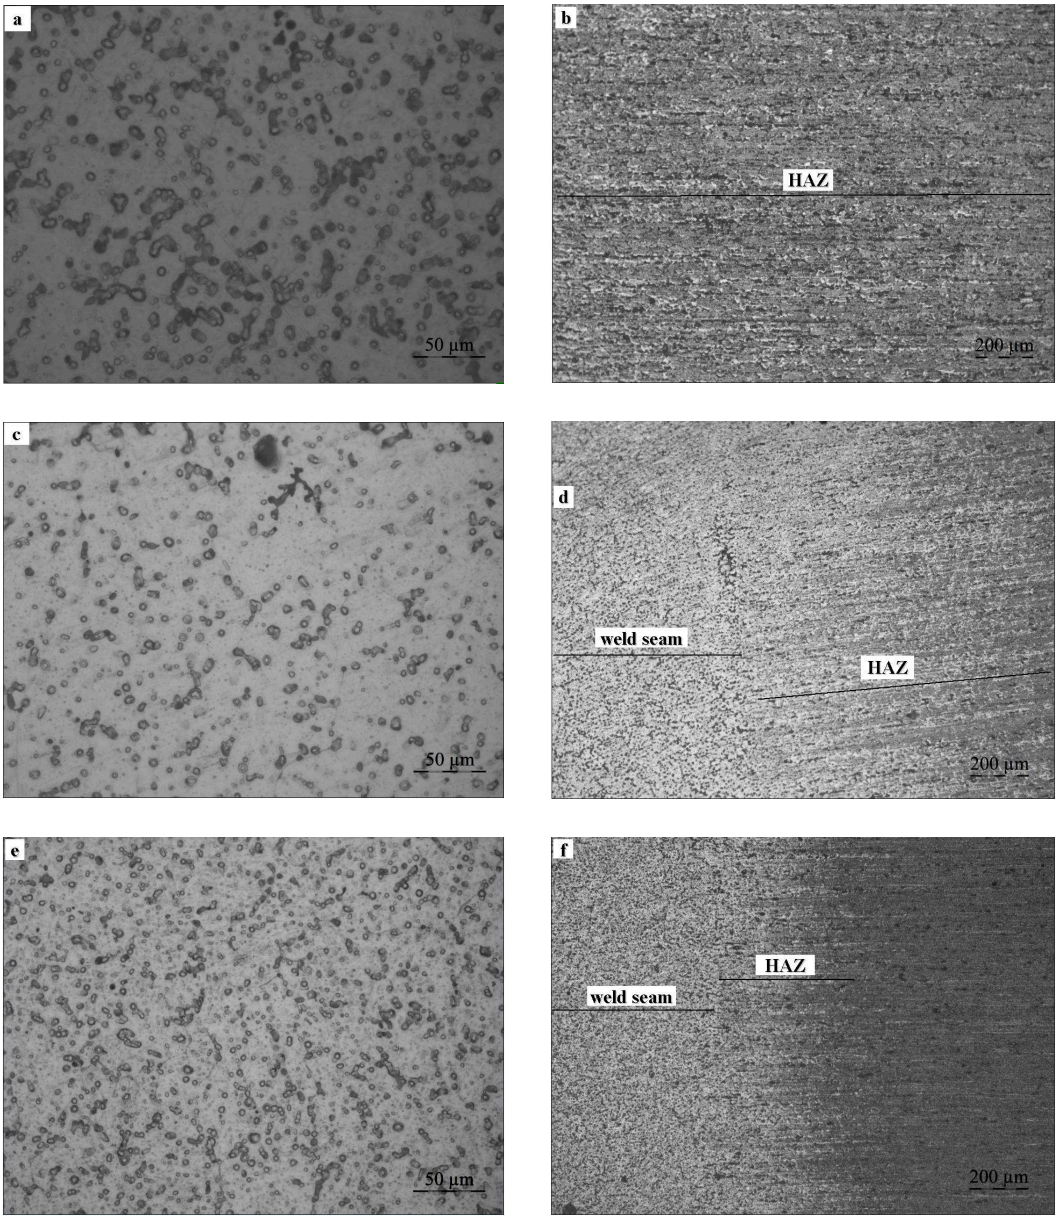
TABLE 2 CHEMICAL COMPOSITION OF ER5356 WELDING WIRE（WT%）

Element	Si	Fe	Cu	Mn	Mg	Cr	Zn	Ti	Al
ER5356	≤0.25	≤0.10	≤0.10	0.05-0.20	4.5-5.5	0.05-0.20	≤0.10	≤0.15	

The aluminum alloys were welded using the PHOENIX series 421 EXPERT forceArc MIG welding equipment (EWM Co.Ltd). The welding processes were finished in an environmental simulation laboratory which can simulate temperature, humidity and wind speed in real circumstance. The entire environment simulation laboratory consists of refrigeration systems, heating systems, humidifiers, dehumidifiers, blower machine and so on. The combination of two-stage low temperature refrigeration units and stainless steel single straight tube heat pipe can control the temperature varied from -30 ℃ to +50 ° C. The range of 20 % to 95% relative humidity can be realized by the combination of ultrasonic humidifier and dehumidifier. The low noise fan can make the wind speed achieve 0m/s-12m/s to simulate wind. The whole system can basically achieve a variety of environmental regulation. The welding parameters are showed in Table 3.

TABLE 3 WELDING PARAMETERS OF A5083-H111 ALUMINUM ALLOY

temperature（℃）	humidity	Wind speed	Plate thickness（mm）	Current (A)	Voltage（V）	Welding speed (cm/min)	Gas flow (L/min)
-20	50%	calm	10	240～260	25～26	300	25
-10	50%	calm	10	240～260	25～26	300	25
20	50%	calm	10	230～260	25～26	330	25
40	50%	calm	10	230～260	25～26	330	25



The cross-section specimens were grounded by sand paper from mesh size 80 to 2000, and then polished. The specimens were etched by mixed acid solution. The composition of corrosive liquid is 1% HF+1.5%HCl+2.5% HNO_3. The microstructures were observed by optical microscope.

The hardness of the welding joint was measured using HVS-30 digital hardness tester with a 29.4N load with dwelling time of 10s. The spacing between hardness points was 1mm.

The tension test was done according to GB/T2651-2008. The test was finished in WDW 3100 computer control electronic universal testing tensile machine. The stretching rate was 1mm/min. The test machine automatically records the load displacement curve. The impact test was carried out according to the GB/T2650-2008. The test was done at room temperature. The gap shape was V-shaped gap. The test machine was JBN -300, which was manufactured by Wztongli Material Testing Machine Co. The absorbed energy value was recorded.

Experiment Results

Microstructure

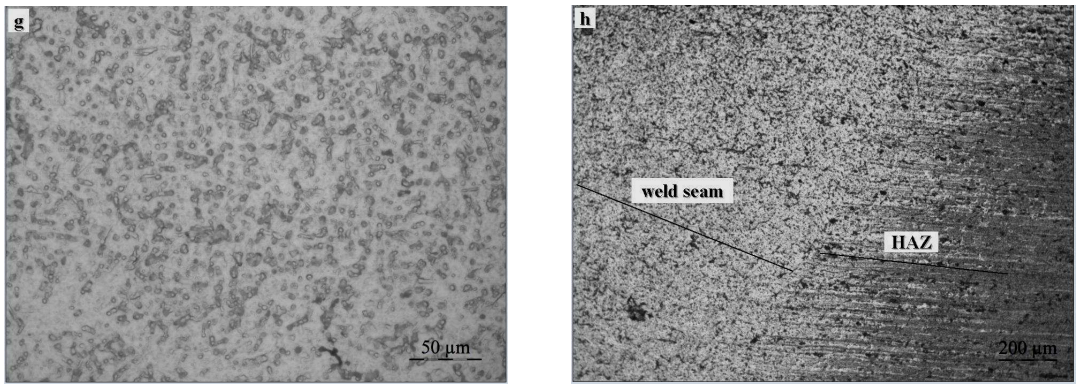


Fig.1 Microstructure of A5083-H111 aluminum alloy welded under different temperature:(a)weld seam at -20 ℃;(b)HAZ at -20 ℃; (c)weld seam at -10 ℃;(d)HAZ at -10 ℃; (e)weld seam at 20 ℃;(f)HAZ at 20 ℃; (g)weld seam at 40 ℃;(h)HAZ at 40 ℃

The microstructures of A5083-H111 aluminum alloy welded under different temperature were shown in Fig.1. It can be seen that the grain size of precipitated phase in welded seam deceased and the content increased with the increase of environment temperature. The width of HAZ decreased with the increase of temperature. The width of HAZ at -20℃ was about 1.5mm, while it was only about 500μm for the welding joint at 40℃.

From the welding parameters listed in Table 3, it showed that the welding velocity at temperature above 0℃was higher than that at temperature below 0℃. Therefore, the cooling velocity after welding was higher and the time precipitated phase stayed at higher temperature was short, which leaded to fine precipitated phase and narrow HAZ.

Mechanical Properties

Hardness test

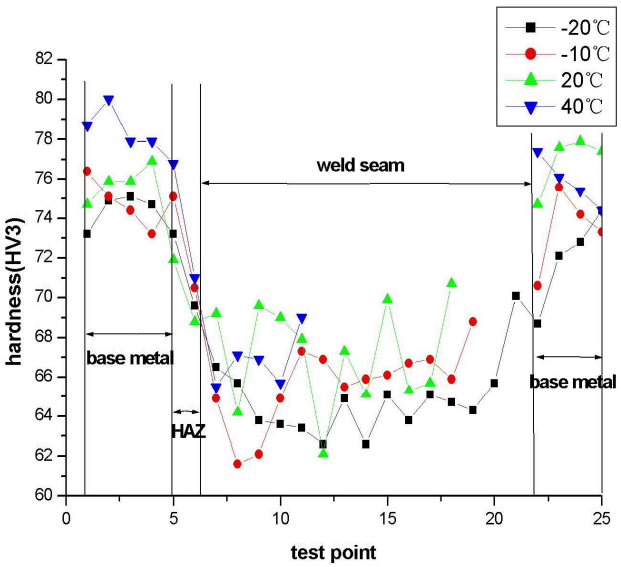

Fig.2 Hardness Distribution Curve Under Different Temperature

The hardness distribution of A5083-H111 aluminum alloy welding joint under different temperature was shown in Fig.2. The points in welded seam were discontinuous at 20℃ and 40℃, because the welded seam was narrower than that at -20℃ and -10℃. It can be seen that the hardness was the lowest in welded seam. The hardness increased with the distance away from

welded centre. The hardness of welding zone of welded joint was generally low below 0 ℃.The A5083-H111 aluminum alloys were annealed condition before welded. The original metallurgical structures were α-Al solid solution and full precipitation of β（Al8Mg5）phase. However, precipitation strengthening effect was not obvious, though the compound can be dissolved in solid solution or precipitated from solid solution in the process of heating and cooling experienced in welding. Therefore, the hardness of HAZ was only slightly lower than the base metal.

Tensile test

Table 4 shows the results of tensile test. It can be clearly seen that most of the specimens welded below 0℃ fractured at welded seam, while most of the specimens welded above 0℃ fractured at HAZ. This indicated that the weak position of joints welded below 0℃ was welded seam. The weak position of joints welded above 0℃ was HAZ. The tensile strength and elongation differed little under different welding temperatures; all of them were in the range of standard requirement.

TABLE 4 RESULTS OF TENSILE TEST FOR WELDING JOINTS UNDER DIFFERENT TEMPERATURE

Welding temperature（℃）	-20	-10	20	40
Average of tensile strength (Mpa)	299	297	310	310

Impact test

Table 6 shows the results of impact test on weld seam. It can be found that the impact energy was slightly higher when the temperature was up to 20℃. .

Welding temperature（℃）	-20	-10	20	40
Average of impact energy /Aku（J）	30.3	28	34	33.8

Discussion

From the mechanical properties of A5083-H111 Al alloy welding joints, it can be found that the strength and plasticity of aluminum alloy welding joints welded at 20℃ and 40℃were both higher than that below 0℃. This may related to the welding thermal cycle experienced. The air temperature directly influenced thermal cycle process, welding pool metallurgy action degree, phase transformation of weld seam and HAZ and alloy element and stress distribution [5].At lower temperature, the heat output velocity was quicker, which can not always promised the aluminum alloy temperature reaching to the requirement of welding process. From Fig.3, the precipitated phase in welded seam below 0℃ was larger and fewer than that welded above 0℃. The improvement in such properties can be explained by the fact that as the size of precipitated phase decreased, the strength and toughness increased according to the Hall-Patch [6] relationship. Thus, the strength and toughness were higher at welding temperature above 0℃ than that welded below 0℃.

Though the mechanical properties of the welding joints welded under different temperatures had slight difference, they all met the standard requirement of A5083-H111 Al alloy welding joints. Literature [2] indicated that low temperature had little effects on the room temperature mechanical of pipeline, but had influence on the low temperature impact toughness. However, it was considered

that little effect on low temperature impact toughness for A5083-H111 Al alloy. It was thought that as an aluminum alloy has a face centered cubic (fcc) crystal lattice, there was no low temperature toughness effect as observed in alloy [7].

Therefore, if the welding parameters were well controlled, A5083-H111 Al alloy can be welded at temperature ranging from -20℃ to 40℃ with relative humidity of 50%.

Conclusions

(1) The grain size of precipitated phase in welded seam deceased and the content increased with the increase of environment temperature. The width of HAZ decreased with the increase of temperature.

(2) The mechanical properties of the welding joints welded under different temperatures all met the standard requirement of A5083-H111 Al alloy. The hardness increased with the distance away from welded centre. The hardness of welding zone of welded joint was generally low below 0 ℃.The strength and toughness were higher at welding temperature above 0℃ than that welded below 0℃. If the welding parameters were well controlled, Al alloy can be welded at temperature ranging from -20℃ to 40℃ with relative humidity of 50%.

Keywords: Surface layer behavior; Process parameters optimization; Experiment research; Grinding; Spiral bevel gears.

Abstract. Based on the test analyses of grinding surface layer behavior of spiral bevel gears, many conclusions are gotten. Compressive residual stresses are occurred on grinding tooth surface, tensile residual stresses are located in tooth layer, and change laws of grinding residual stresses are different from ones of grinding surface roughness R_a as the grinding process parameters. A temper layer is occurred in tooth layer after normal grinding, and the micro-hardness of grinding surface is lower. When arriving at the critical condition, namely grinding temperature is above 600 degree Celsius, and metamorphic layer depth is greater than 0.2mm, different degree of grinding burn is produced, and their microstructures are changed. Based on grinding orthogonal test $L_{16}(4^5)$, the optimizing configuration of grinding process parameters of spiral bevel gear is obtained by using a mean variance analysis of integrated balance method. Based on the test optimization of grinding surface layer behavior, the comprehensive performances of grinding surface, such as grinding residual stresses, surface roughness, micro-hardness and structure, metamorphic layer depth et al, are better. These provide a basis for improvement of grinding surface quality of spiral bevel gears.

Introduction

Spiral bevel gears are crucial components achieved the motion transmission of intersectant axes, and they are used widely in energy sources, traffic, military industry and so on. Its precision finishing method is generally the multi axis NC grinding. The grinding surface layer behavior is affected by grinding process parameters, and the transmission performance and usage safety of spiral bevel gears are restricted seriously by grinding surface layer behavior.

The grinding surface layer behavior is comprised of a grinding surface residual stresses, surface roughness, surface hardness and metamorphic layer depth, grinding burn and so on. Foreign scholars NABIL et al. compared with the grinding quality of austenitic stainless steel under different grinding conditions by test, the results showed that the grinding surface quality had been improved when the low temperature cooling grinding [1]. Based on the grinding test data, SAHIN established the prediction model of surface roughness by using response surface method [2]. By means of test data, CHEOL et al built up the intelligent models of material removal rate, surface roughness, grinding residual stress and so on for the grinding of cylindrical insert type [3]. Domestic scholars Tian etc obtained the optimal test results of ceramic grinding based on orthogonal test design [4]. Du made a fuzzy comprehensive evaluation of grinding process by using the theory of fuzzy mathematics [5].

The above researches object were mainly grinding ones of simple parts, such as plane, cylinder parts, and so on, but it is rarely reported for the research of grinding surface layer behavior and process parameter optimization of spiral bevel gears with space shape and complex processing.

Grinding Experiment Conditions of Spiral Bevel Gears

Gear Material and Machining Process

Here 20CrMnTi of spiral bevel gears was commonly selected in automobile gear material. The machining processes and technical requirements in experiment of spiral bevel gear pair were expressed as: Baiting → Blank forging → normalizing → milling teeth → carburizing, quenching and tempering →grinding tooth. Effective hardening layer depth was 0.80~1.20mm,surface hardness was 58~62 HRC,and centre hardness was 30~42 HRC.

Grinding Process Conditions

Specimen was processing in PHOENIX450PG grinding machine with the straight cup wheel SG60-JV. Grinding way was out-cut inverse grinding, and the oil-base extreme pressure grinding fluid was used. Small gear was processed in generative grinding with single-sided method, and big gear was grinded with double-sided method [6].Basic parameters of spiral bevel gear pair were listed in table 1, and their adjusted parameters of grinding machine were listed in table 2.

TABLE 1 BASIC PARAMETERS OF THE SPIRAL BEVEL GEAR PAIR

Item	Parameters		Item	Parameters	
	Small gear	Big gear		Small gear	Big gear
Teeth Number	z_1=15,right spin	z_2=46,left spin	Pitch cone angle(°)	δ_1=18.0605	δ_2=71.939 5
Module m(mm)	8.22	8.22	Root cone angle(°)	δ_{f1}=16.427 3	δ_{f2}=68.658 5

Experimental Analysis of Grinding Surface Layer Behavior of Spiral Bevel Gears

Experimental Analysis of Grinding Residual Stress

Grinding surface residual stress was measured by X-ray diffraction method, a text equipment was Japanese D/Max 2550 18KW turn target X-ray diffractometer.

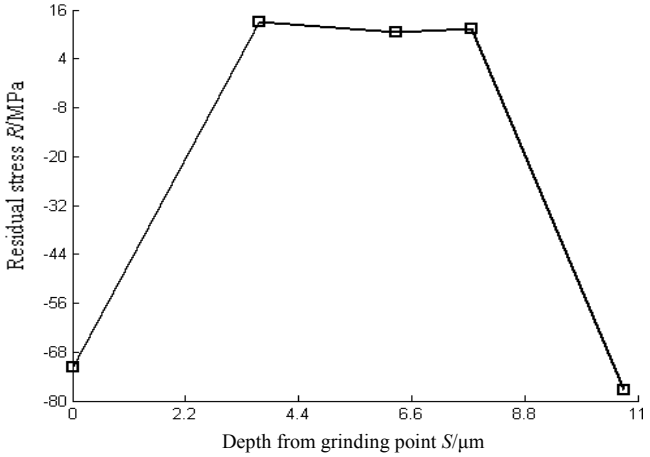

Fig. 1 Test distribution curve of grinding residual stresses of big gear

On the condition of grinding dosage of big gear concave, grinding depth a=0.03 mm, wheel speed v_s =30 m/s and gear generating speed v_w=4 m/min, the residual stresses of five depth node from big gear grinding point were measured by test after grinding, and the test distribution curve of grinding residual stress was shown in Fig. 1. The first and the fifth node were respectively the one on concave and convex.

Further experimental results showed that the residual stresses on grinding tooth surface of spiral bevel gears were residual compressive stresses, and the ones in tooth layer were residual tensile stresses. The residual stresses of grinding layer would be increased rapidly as magnifying v_s, and when a was greater than 0.03 mm, grinding surface residual stresses were increased rapidly as increasing a, but the ones would be decreased as increasing v_w.

Experimental Analysis of Grinding Surface Roughness

The surface profiler instrumentation Hommel Werke T8000 made in German was used in the measurement of grinding surface roughness. The R_a of tooth surface was measured three times each, and its average value was the experimental measuring one of R_a.

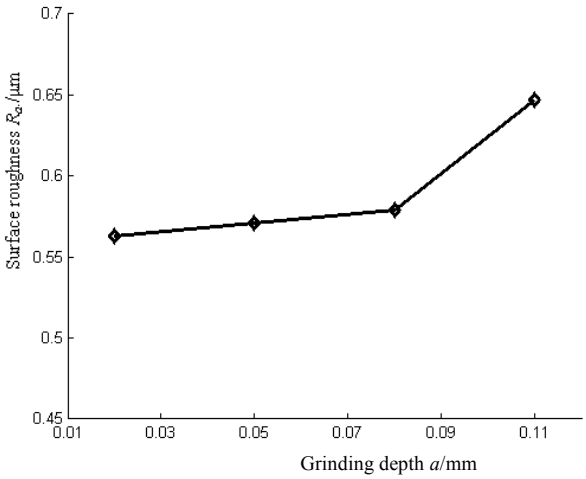

Fig. 2 Test Distribution Curve of *Ra* and *a* When Grinding Big Gear Concave

On the condition of grinding dosage of big gear concave, v_s=20.6 m/s and v_w=3.1 m/min, when grinding depth a was respectively taken for 0.02, 0.08 and 0.11mm, the test distribution curve of R_a and a was shown in Fig. 2. The results indicated that when a was less than 0.08 mm, the value R_a was increased slightly with the enhance of a; but when a was greater than or equal to 0.08 mm, the value

R_a was increased significantly with improvement of a. This showed that the smaller a had little impact on R_a, and on the normal grinding stage without passivation, grinding efficiency was improved by increasing a appropriately.

The experiment also showed that the value R_a was decreased significantly as increasing v_s, but the one was increased slightly as enhancing v_w. With the increase of grinding granularity, the value R_a was decreased gradually, and smaller granularity would make the roughness change slowly.

Experimental Analysis of Grinding Layer Micro-hardness and Metamorphic Depth

When measuring of grinding layer micro-hardness and metamorphic depth, grinding layer micro-hardness was measured by automatic micro-hardness tester Lecd AMH2000.While grinding concave of big spiral bevel gear, v_s=52.1m/s, v_2=3.1m/min,grinding depth a are respectively taken for 0.02, 0.08 and 0.11mm, the distribution curves of layer micro-hardness and a were shown in Fig. 3.

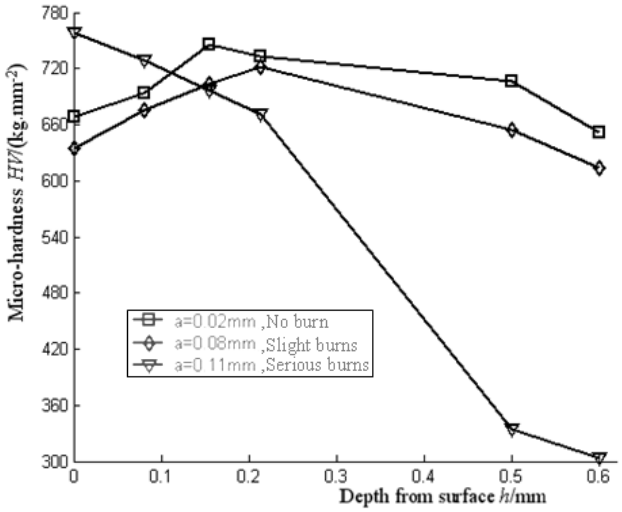

Fig. 3 Distribution curves of layer micro-hardness and a when grinding big gear concave

As shown in Fig. 3, when a=0.02mm, burn in layer was not produced, and a tempering softening layer was produced. The layer mcro-hardness HV was 669HV (equivalently 59 HRC), thus grinding surface hardness requirement was satisfied. The highest hardness of inner layer was 745HV, tempering layer depth h, 0.155mm, was shallow. When a was 0.08mm and grinding temperature was more than 600 degree Celsius, slight tempering burns in layer were produced, surface micro-hardness was 635HV (equivalently 57.4 HRC), and it was inferior to one of grinding surface hardness requirement. The highest hardness of tempering layer was 722HV, and tempering layer depth h, 0.213mm, was increasing. When a was 0.11mm, serious quenching burns in layer were produced, and surface micro-hardness was 758HV (equivalently 63.1 HRC), it was greater than one of grinding surface hardness requirement, and burns layer depth h was 0.5mm.

The experiment also showed that h increased with the enhance of v_s, but slightly reduced with the increase of v_w in the same other grinding conditions.

Experimental Results and Analysis of Grinding Microstructure

The microstructure of grinding hardening layer was observed and analyzed through the metallographic microscope. Before the observation tooth was firstly cut into specimens by wire-electrode cutting. The specimens were eroded with 4% nitric acid alcohol solution after polishing, and their structure were observed by German Leica-DM IRM metallographic microscope.

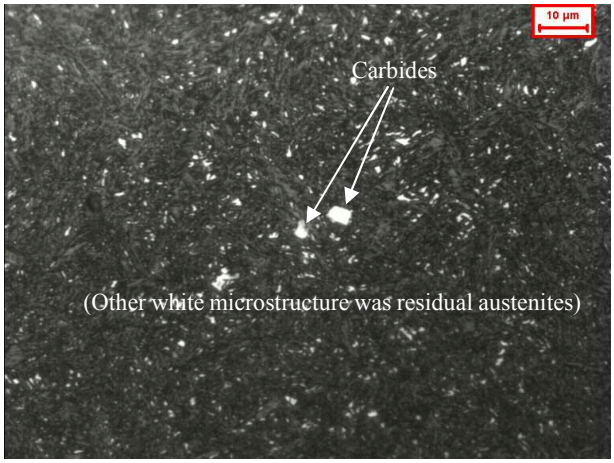

Fig. 4 Surface microstructure of no burn when grinding big gear concave (1000×)

1) Grinding unburned microstructures

When grinding concave of big spiral bevel gear, grinding dosage a =0.02 mm, v_s =52.1 m/s, v_2 =3.1 m/min, burn was not taken place in grinding tooth surface, tooth surface microstructures were acicular martensites + residual austenites + a small amount of carbides, their microstructures were shown in Fig. 4. While The microstructures of central tooth were lath martensites + bainites + a small amount of ferrolites. The bainites were mainly feathered upper ones, and were a small amount of granular ones.

2)Microstructures of grinding burn

When a was 0.11mm,v_s was 52.1m/s and v_2 was 3.1m/min, severe quenching burns were took place in grinding concave of big spiral bevel gear, and they were line form with steel-gray. Maximum depth of burns was 0.5mm approximately; the cementite layer distribution was shown in Fig. 5, and the crescent-shaped area with blanch color was martensite one formed by quenching burns. The layer microstructure was shown in Fig. 6, the area from surface to inner was divided into quenching burn and temper burn area.

The burn layer microstructures near surface of quenching burn area (place A in Fig. 6) were acicular martensites + residual austenites + a small amount of carbides, and there were more martensites in this area. This showed that grinding temperature in this area already achieved A_{Ccm} of material or overtaked A_{C3}. The microstructures beneath quenching burn area(near the temper burn area, namely place B in Fig. 6) were martensites + ferrolites + residual austenites, and the microstructures from top to bottom of in temper burn area were deep black troostite and temper sorbite.

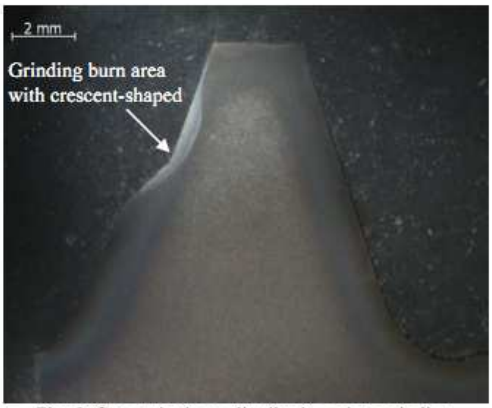

Fig. 5 Cementite layer distribution when grinding big gear concave

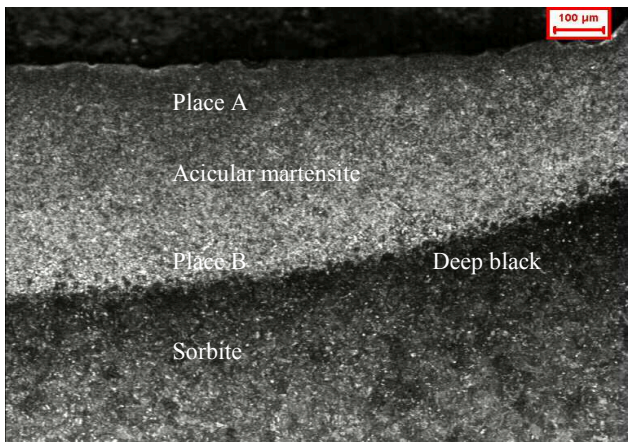

Fig. 6 Burn layer microstructure when grinding big gear concave (100×)

Further studies showed that, when reaching a critical condition, namely the grinding temperature was higher than 600 degree Celsius, metamorphic layer depth was greater than 0.2mm, different degree grinding burns were produced, and the surface micro-hardness was higher while severe burns.

Grinding Orthogonal Test Analysis and Process Parameter Optimization of Spiral Bevel Gear

Grinding Orthogonal Experimental Design and Results

1) Grinding orthogonal experimental design

Grinding process and parameters had a greater impact on the grinding surface layer behavior and productivity. When designing orthogonal experiment and considering four variational factors, such as grinding depth a, wheel speed v_s, grinding wheel granularity M and gear generative speed v_w, these factors were chosen as orthogonal factors [5]. According to the grinding experience value, four different level values were taken in each factor, and these factors and levels of grinding orthogonal experiment were listed in table 3.

TABLE 3 FACTORS AND LEVELS OF GRINDING ORTHOGONAL EXPERIMENT

level	Grinding depth A(mm) A	Wheel speed v_s(m·s^{-1}) B	Wheel granularity M(#) C	Generative speed v_w(m·min^{-1}) D
1	0.02	16.5	46	2.7
2	0.05	26.5	60	3.6
3	0.08	35.2	80	4.4
4	0.11	52.6	120	7.2

2) Grinding orthogonal experimental results

To consider the grinding surface layer behavior and productivity, three index of grinding experimental evaluation, such as surface roughness R_a, metamorphic layer depth h and grinding removal rate Z_w, could be chosen. According to four certain factors and levels, orthogonal table L_{16} (4^5) was used [3], and a blank column 5(e) was put apart in the table to use in variance analysis [6].16 set of experiments were done, and the orthogonal experimental results of grinding concave of small spiral bevel gear were listed in table 4 (except comprehensive evaluation index value).

TABLE 4 GRINDING ORTHOGONAL EXPERIMENT RESULTS OF SMALL GEAR CONCAVE

Experiment No.	1 A	2 B	3 C	4 D	5 e	Surface roughness R_a(μm)	Deterioration depth h(mm)	Removal rate Z_w(mm^3·s^{-1})	comprehensive evaluation indexs
1	1	1	1	1	1	0.543	0.041	0.185	6.4380
2	1	2	2	2	2	0.524	0.048	0.197	6.6153
3	1	3	3	3	3	0.417	0.058	0.248	7.9934
4	1	4	4	4	4	0.425	0.061	0.314	8.1117
5	2	1	2	3	4	0.554	0.073	0.362	6.5220
6	2	2	1	4	3	0.581	0.069	0.479	6.7140
7	2	3	4	1	2	0.526	0.083	0.357	6.6977
8	2	4	3	2	1	0.567	0.089	0.413	6.3216
9	3	1	3	4	2	0.756	0.087	0.495	4.3356
10	3	2	4	3	1	0.729	0.112	0.482	4.2397
11	3	3	1	2	4	0.732	0.129	0.611	4.4589
12	3	4	2	1	3	0.728	0.132	0.544	4.1961
13	4	1	4	2	3	0.871	0.135	0.569	2.4775
14	4	2	3	1	4	0.801	0.146	0.643	3.4735
15	4	3	2	4	1	0.901	0.155	0.651	2.1293
16	4	4	1	3	2	0.851	0.173	0.687	2.6198

Because different levels of four factors in experiment have different impact on three experimental evaluation index, the gotten optimal scheme of each index was not consistent. In order to obtain the final solution of optimal grinding process parameters taken compatibly into account R_a, h and Z_w index, integrated balance method could be used to analyze [5]. Let single factor evaluation index set U be $\{ y_{mn} \}$, which y_{mn} was respectively three evaluation index in table 4,and m was 1,2,3,also n was 1,2,⋯,16.The influence function set Π of experimental index was $\{ \eta_{mn}\}$, which η_{mn} was between 0 and 10. Assuming that the impact function value η_{mn} of the best experiment index was 10,all impact function values were determined proportionally by the difference between other experimental values and the best index.

Let comprehensive evaluation index set be V gotten by comprehensive balance method. In order to find the relationship between U and V, the weight distribution set γ was determined to be $\{\gamma_1, \gamma_2, \gamma_3\}$, and it reflected the importance of each index. According to grinding process technology requirements of spiral bevel gears, the weight distribution set γ could be determined to be {0.4,0.2,0.4}. All comprehensive evaluation index v_n in set V of $\{v_n\}$ was

$$v_n = \sum_{i=1}^{m} \gamma_i \eta_{in} \qquad (m = 1,2,3; n = 1,2,\cdots,16) \tag{1}$$

Based on the equation (1), the evaluation index of three single factor in table 4 was calculated, comprehensive evaluation index obtained were listed as the last column in table 4.

Grinding Orthogonal Experimental Analysis and Process Parameter Optimization

Range analysis and variance analysis method was usually used in process optimal analysis of orthogonal experimental results, and range analysis method was mainly to estimate the effect strength of all factors. In order to further analyze the significance and accuracy that process parameters impacted on the experimental results, the variance analysis of integrated balance method was used in grinding orthogonal experiment of small gear concave, and the analytic results were listed in table 5.

TABLE 5 VARIANCE ANALYSIS OF INTEGRATED BALANCE METHOD

Variation soruce	Deviation of square sum S	Freedom degree f	Sum of mean square $MS(S/f)$	F value (MS/MS_e)	Critical value	Significance
A	53.5920	3	17.8640	32.8402		▲▲▲
B$^{\triangle}$	0.3849	3	0.1283			
C$^{\triangle}$	1.0971	3	0.3657		$F_{0.01}(3,12)=5.95$	
D$^{\triangle}$	0.3562	3	0.1187		$F_{0.05}(3,12)=3.49$	
Error e	1.6319	3	0.5440		$F_{0.1}(3,12)=2.61$	
$e^{\triangle}$	3.4701	12	0.2892			
Total T	57.0621	15				

Known from table 5, factor a have highly significant effects on the experimental results. According to the bigger value k, level A_1 was chosen. The influencing degree of other three factors was not significant, level B_3,C_3 and D_3 could be selected separately. Thus the optimal scheme determined was $A_1B_3C_3D_3$, namely a=0.02mm, v_s=35.2 m/s, M=80$^{\#}$, v_w=4.4 m/min.

Experimental Optimization Analysis of Grinding Surface Layer Behavior of Spiral Bevel Gear

The experimental results of grinding surface layer behavior of small gear concave were listed in table 6 by test in general process parameters and the optimal process $A_1B_3C_3D_3$.

TABLE 6 TEST RESULTS OF GRINDING SURFACE LAYER BEHAVIOR OF SMALL GEAR CONCAVE UNDER GENERAL AND OPTIMAL PROCESS PARAMETERS

Grinding scheme	Grinding process parameters				Experimental values of grinding surface layer behavior			
	a (mm)	v_s ($m \cdot s^{-1}$)	M ($^{\#}$)	v_w ($m \cdot min^{-1}$)	Surface residual stress(MPa)	Surface roughness R_a(μm)	Surface hardness (HRC)	Deterioration depth h(mm)
General process	0.02	16.5	46	2.7	-49.52	0.543	61.1	0.041
	0.05	16.5	60	4.4	-60.73	0.554	59.7	0.073
	0.08	52.6	60	2.7	-65.87	0.728	57.5	0.132
	0.11	26.5	80	2.7	-70.14	0.801	58.3	0.146
Optimal process	0.02	35.2	80	4.4	-65.41	0.417	60.2	0.058

Comparing with the grinding surface layer behavior under general process parameters in table 6, the grinding surface residual stress under optimal process parameters was better of residual compressive stress (-65.41 MPa), grinding surface roughness values were smaller, grinding surface hardness was of satisfying the requirement (58~62 HRC), and grinding metamorphic layer depth was shallower(0.058 mm). In addition, known from grinding orthogonal experiment results in table 4, removal rate Z_w was reached 0.248 mm^3/s, comprehensive evaluation index was higher (7.9934). This showed that the comprehensive performance of grinding surface quality was better under the grinding process optimization.

Conclusions

(1) Grinding experiment shows that the residual stresses of grinding surface of spiral bevel gear are residual compressive stresses, and the ones in tooth layer are residual tensile stresses. The residual stresses of grinding layer are increased markedly as magnifying v_s, but the ones are decreased as increasing v_w. When a is greater than 0.03 mm, grinding layer residual stresses are increased obviously as increasing a. The value R_a of grinding surface roughness is decreased significantly as increasing v_s, but the one was increased slightly as enhancing v_w. When a is greater than or equal to 0.08 mm, the value R_a is increased significantly with improvement of a. A temper layer is occurred in tooth layer after normal grinding, and the micro-hardness of grinding surface is lower. When arriving at the critical condition, namely grinding temperature is above 600 degree Celsius, and metamorphic layer depth is greater than 0.2mm,different degree of grinding burn is produced, and their microstructures are changed. The microstructure of quenching burn area is different from one of temper burn area, the micro-hardness of tooth surface while quenching burn is increased obviously while quenching burns.

(2)Based on the results of grinding orthogonal experiment $L_{16}(4^5)$, the variance analyses is made by the integrated balance method, and optimal combination of grinding process parameters of spiral bevel gear is $A_1B_3C_3D_3$, namely the grinding depth a is 0.02mm, wheel speed v_s is 35.2 m/s, wheel size M is $80^{\#}$, gear generative speed v_w is 4.4m/min.

(3)Comparing with the grinding surface layer behavior under general process parameters, the value R_a of grinding surface roughness under optimal process parameters is more less 0.1μm, the surface residual stress is -65.41MPa, surface hardness is of satisfying the requirement, grinding metamorphic layer depth is shallower (0.058 mm), and the grinding surface comprehensive performance is better.

Keywords: Permanent magnet generator, Magnetic field, Micro electroforming, Magnetic circuit structure

Abstract. To provide appropriately high and uniform magnetic field for micro electroforming process, a permanent magnet generator was specially developed which based on the fundamental process requirements. On the basis of determining the number of permanent magnet combinations numerically. Mainly, the geometrical shape of the permanent magnet blocks and magnetic circuit structure were optimized, and then the working gap regulating mechanism for this generator was designed. Utilizations indicated that the developed generator met the requirements well.

Introduction

As one of the main processes of forming metal microstructures and microcomponents, micro electroforming technique has some unique advantages including high replication precision, low process temperature, favorable flexibility, and low cost, etc..It has been widely employed in the field of micro-and nano-manufacturing. However, the micro electroformed articles usually feature some defects, such as pinholes, nodules, and hydrogen embrittlement, due to serious mass transfer limitation during the deposition. Since the deposition articles electrodeposited under the magnetic field have been found to show good surface quality and/or interesting microstructures and properties owing to some magnetic field effects (i.e., MHD effect, magnetic force effect, magnetizing force effect), the studies of magnetic field assisted electrochemical deposition technique has been an attractive topic in the academia and industry field. Ming et al. [1] discussed the mechanism of electrodeposition within high-aspect-ratio micro holes exposed to magnetic field, and analyzed the influence of process parameters on surface morphology and performances of nickel layer. The research by Coey et al. [2] showed that the use of magnetic field in the electrodeposition can enhance deposition rate of magnetic or non-magnetic species resulting from the induced turbulence. At present, the magnetic fields generally used in the electrodeposition processes are mainly electromagnetic field and permanent magnetic field. Electromagnetic field can easily achieve high strength and is easy to adjust in terms of magnitude and direction. In addition, it can provide suitably high intensity magnetic field for the electrodeposition process with a big interelectrode gap. But it has some limitations in the industrial applications because the generation of electromagnetic field needs costly and complex devices as well as various cooling apparatuses, leading to high process and maintenance cost. Although the permanent magnetic field is very difficult to obtain a magnetic field with an intensity of more than 1T in the interelectrode gap, it can offer favorably high value for the electrodeposition process at a very low cost and with almost no maintenance. In contrast, permanent magnetic field is more attractive for the conventional electrodeposition practices. However, it is not easy to get uniform high-intensity magnetic field in the entire working-area at a relatively wide gap due to inherent limitations of permanent magnet materials. Thus, it still needs further research to explore more effective generator that can meet the requirements of magnetic field assisted micro-electroforming process. Although some papers [3-5] reported some permanent magnet generators employed for the electrodeposition process, but they were still not satisfactory. To this end, this paper specifically introduces a novel permanent magnet generator for the micro electroforming process.

Overall Design and Requirements

The system of magnetic field assisted micro-electroforming process was mainly composed of magnetic field generator, electrodeposition cell unit and electrolyte circulation unit, etc..The electrodeposition cell unit was located in the gap between the N pole and S pole of permanent magnets. Taking into consideration of the fundamental requirements, cost and practicability of the micro-electroforming process, the permanent magnet generator should have the following functions: (1) it can provide uniform constant magnetic field in the entire gap space, and the magnetic field intensity in the central region is over 0.8T; (2) the magnetic field intensity can be changed uniformly with the variation of the working gap; (3)the effective area that is subjected to uniform constant magnetic field is not less than 100 mm×100 mm; And (4) it is significantly easy to make with a high throughput efficiency and an extremely small magnetic leakage, as well as a low cost. To achieve the above requirements, the key is the optimization design of magnetic circuit structures and regulation mechanism of interelectrode gap.

Optimization Design of Magnetic Circuit Structure

The core tasks of magnetic circuit structure design include selection of permanent magnet and aggregation magnet material and determination of magnetic circuit structure. In terms of practicability and economy, we chosen commonly-used rubidium iron boron magnet (50M: 1400mt<Br<1450mt) and industrial pure iron (DT4:$\mu'_{max}\geq 6000\mu m$) as the material of permanent magnet and aggregation magnet respectively. At the same time, as described above, in order to meet the basic requirements of magnetic field assisted micro electroforming process, uniform magnetic field area is not less than 100 mm×100 mm and NS interpole distance is not less than 30 mm. Obviously, under the given conditions, how to achieve as high as possible (at least 0.8 T) uniform magnetic field in the gap is the goal of optimization design of magnetic circuit structures.

According to the Kirchhoff's first and second law, in order to obtain desired magnetic gathering effect, the magnetic circuit structure is expected to be closed and have a good symmetry. The ideal structure of magnetic circuit was shown in Figure 1. Since different magnetic fields are required during the electrodeposition, the working gap between magnetic poles should be adjustable. Therefore, we divided the aggregation magnet into two parts: inner [-shaped part and outer]-shaped part (shown in Figure 2).The inner [-shaped part and outer]-shaped part were assembled through the alignment of the rabbets which were respectively configurated in the two side-arms of the above aggregation magnets. Two magnet combinations containing the same number of magnet blocks were stalled at the center of the bottoms of the inner [-shaped part and the outer]-shaped part respectively, with the surfaces of the combination being parallel. According to design experiences and analysis

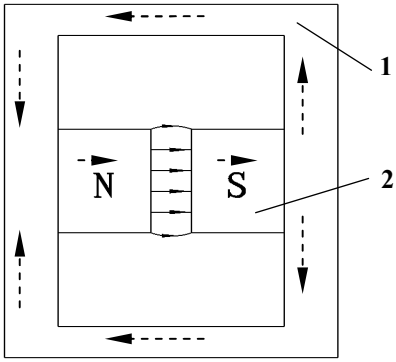

Fig.1 Schematic Diagram of the Permanent Magnet Structure
1. Aggregation Magnet; 2. Permanent Magnet

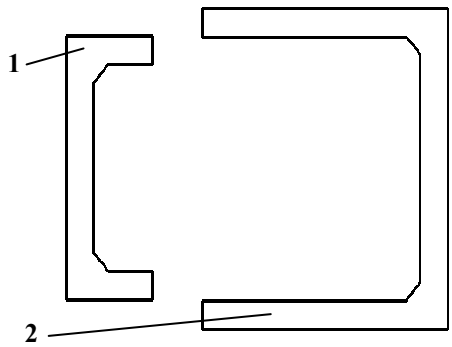

Fig.2 Schematic Representation of Assembled Magnetic Structures
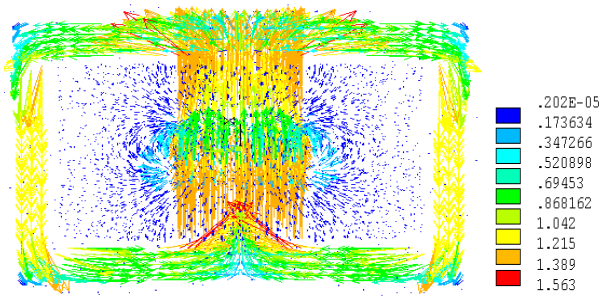
1. Inner [-shaped part; 2. Outer]-Shaped Part

results, the thickness of the side arms of the two aggregation magnet parts was selected to be30 mm, and that of the bottom sides was designed to be 40 mm. In addition, the width between the two side-arms of the outer]-shaped part was 300mm. Because the resulting magnetic field strength of the magnet combinations is, to some extent, dependent on cross section shape of permanent magnet

involved, the cross section shape was specially studied numerically using the magnetic mirror image method [6] based on Matlab software. Eventually rectangle cross section was adopted as it was proved to have the capability of achieving higher magnetic field intensity. On the other hand, previous research indicated that the surface residual magnetization of the magnet combinations increases with increasing of stacking number, and then becomes almost unchanged when the stacking number reaches the limitation[7].To meet the requirements for conventional applications, we chose 7 pieces of permanent magnet blocks (cross section100 mm×100 mm and thickness 10mm) to form the magnet combinations.

For the sake of simplicity and accurate analysis, a three-dimensional physical model on the basis of the simplified magnetic circuit structures was established. The calculation results obtained by using Ansys software was illustrated in Figure 3. Almost all high intensity magnetic fields was



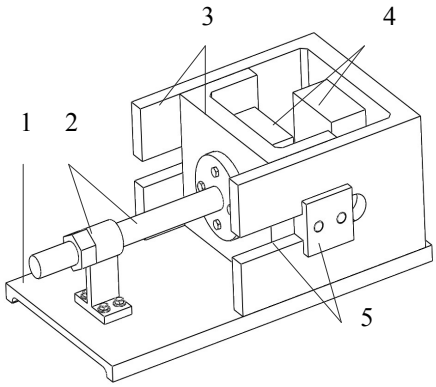


Fig.3 Distribution of Magnetic Field Obtained from Numerical Analysis

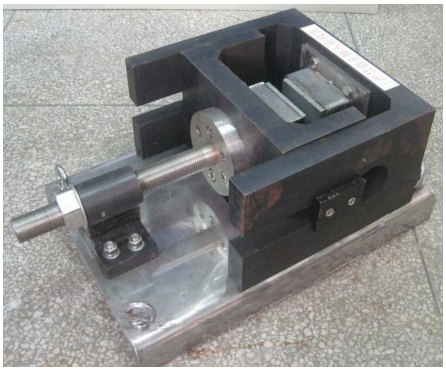

gathered in the space of the working gap with the intensity of 0.868162T, and the other regions showed extremely little magnetic field. These findings verified that the design totally realized the goal.

Design of Working Gap Regulating Mechanism

To realize the adjustment of the working gap between N and S pole, we designed a nut-screw mechanism which linked the bottom arm of the inner [-shaped part to drive one of the permanent magnet assemblies to move linearly. In addition, a chute-slider was installed into each side-arm of the inner [-shaped part and the outer]-shaped part to facilitate to make the working gap change uniformly and stably. In order to remarkably reduce the loss of magnetic field from the working gap during the adjustment, T-shaped slider was adopted with the alignment between the inner wall of slider head and the outer wall of the side-arm in the outer]-shaped part. The schematic of adjusting mechanism was shown in Figure 4.

Conclusions

Based on the fundamental process requirements as well as practicality, we explored a magnetic field generator for the magnetic field assisted micro electroforming technique. After choosing the materials of permanent magnets and aggregation magnet, we optimized the geometrical shape of the permanent magnet blocks and magnetic circuit structure, and then determined the number of permanent magnet combinations numerically. Furthermore, we designed the working gap regulating mechanism for this generator. Measurements showed that magnetic field intensity of the central region was 0.867T, the generator worked well.

Keywords: Heat treatment, heat transfer coefficient, strip cooling, cooling intensity, sheet cooling, spray, water cooling, stainless steel

Abstract: Stainless steel sheets are successively heated to a temperature of 1150°C and cooled until ambient temperature during the production process. Requirements for high cooling rates of stainless steel sheets producers lead to use water as a cooling medium. The information about cooling intensity (heat transfer coefficient) of different nozzles configurations is necessary for designing cooling sections. Although many researchers deal with water spray cooling, actually a general correlation for predicting heat transfer coefficient for wide range of nozzles configurations does not exists. That is the reason why heat transfer coefficient for different nozzles configurations can be only obtained by laboratory measurements. Heat transfer coefficient is mostly influenced by water impingement density and impact velocity. However other factors e.g. water temperature and velocity of the sheet can influence the heat transfer coefficient. Optimized design of the cooling unit with high cooling intensity and low water consumption was achieved by appropriate choice of these parameters. The moving experimental sheet was cooled from a temperature of 900°C to a temperature of 50°C with various configurations of nozzles. The tests shown that heat transfer coefficient was increasing with water impingement density and impact velocity. Increasing water temperature from 20 °C to 80 °C caused a decrease of the heat transfer coefficient and Leidenfrost temperature. The effect of velocity is negligible when velocities are between 25 and 100 m/min. The cooling unit was designed according to laboratory measurements to fulfill the stainless steel producer's requirements. The measurements which were done in an industrial plant confirmed the accuracy of heat transfer coefficient obtained in the laboratory. The maximum difference between laboratory and plant measurements was 15%.

Introduction

Water is used as a cooling medium during the annealing of stainless steel strips because the producers require high cooling rates and cooling homogeneity to avoid thermal distortions [1]. The cooling intensity has to be known to design the cooling unit. Although many researchers are focused on water spray cooling, general correlation which predicts the cooling intensity for wide range of nozzles and spray parameters does not exist. The cooling intensity is often represented by heat transfer coefficient. Formulas described in papers usually use only water impingement density to compute the heat transfer coefficient [2]. Heat transfer coefficient is mostly influenced by water impingement density but it is also influenced by impact velocities and many other factors. They can be for example: water temperature, strip velocity, surface quality, etc [3][4]. This is the reason why the laboratory measurements of heat transfer coefficient for various cooling parameters are necessary to predict the cooling intensity.

Fives Stein company is concerned with designing of cooling sections for carbon and stainless steel annealing. Their object was to design a cooling section of stainless steel strips where stainless strips of thickness between 1 and 6 mm will be cooled rapidly to avoid precipitation of carbides without thermal distortions of the strip and with low consumption of water. They cooperate with the Heat Transfer and Fluid Flow Laboratory where the tests were done to obtain heat transfer coefficient for

various cooling unit set. This knowledge gives possibility to simulate cooling of the strip for various parameters and find optimal design of cooling section. The sizing part and final design was done by Fives Stein company.

Experimental Part – Experimental Equipment and Procedure

Heat Transfer and Fluid Flow Laboratory is equipped by testing devices to simulate cooling during continuous casting, hot rolling and heat treatment. The objective of the experimental part was a description of the influence of five parameters on the cooling intensity - water pressure (flow rate), nozzle span, gravity, velocity of the strip and water temperature.

Experimental Equipment

A special cooling unit was built for laboratory measurements. It was compound of eight rows of nozzles. This system allowed changing nozzle span very easily. It was mounted under and below the linear stand to simulate upper and bottom cooling. The Linear stand is six meters long rotatable girder with a trolley on which was installed experimental sheet. Trolley moved the tested sheet reversibly through the cooling section with defined velocity. An austenitic, 1.5 mm thin sheet was used as an experimental plate (Fig. **1** – hot surface) because of its resistance to material oxidation and because phase changes do not occur in this material. Five thermocouples were welded to the bottom side of the sheet (the front side of the sheet is sprayed by water). The data-logger was positioned also on the trolley and it was moving together with the sheet and it recorded measured data with very high frequency of 320 Hz. These data represented the temperatures from the bottom side of the tested sheet. So the surface temperature, the heat flux and the heat transfer coefficient were computed by inverse task.

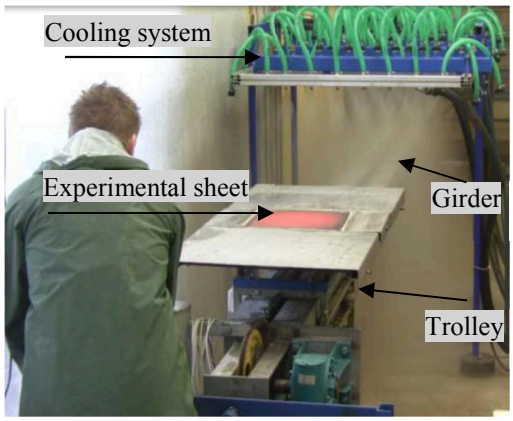

Fig. 1 Experimental device with hot experimental sheet – upper cooling with cluster of nozzles

Experimental Procedure

Each experiment started by heating of the sheet to the initial temperature (900 °C). The tested plate was oriented by surface down and it was inserted into the electrical furnace. The temperature regulator controlled heating and the furnace power. The inert atmosphere protected the surface of the sheet against oxidation. The water pump was switched on when the initial temperature was reached. The required water pressure and flow rate was set and the sheet was moved out from the furnace. Then the surface orientation was set. The surface was oriented down for bottom cooling and by rotating the girder of 180° the surface was oriented up for upper cooling. The trolley moved reversibly the tested sheet through the cooling section until the temperature of the sheet was lower than 50 °C. The data recorded by the data-logger were downloaded to the computer as soon as the experiment ended.

Data Processing

The temperatures were measured on the non-sprayed side of the test plate. A value of Biot number shows that the heat conduction inside the sheet is much faster than heat convection on the surface. When the Biot number is lower than 0.1 the temperature gradients in material are negligible [5]. The Biot number in this case is grater then 0.1 so the inverse task has to be used for data processing. A difference between surface and measured temperature is shown in Fig. 2 (on the left). The Beck's sequential algorithm was used to compute the heat fluxes. The surface temperature and heat transfer coefficient were easily computed by using standard formulas. The graph in Fig. 2 (on the right) shows an example of heat transfer coefficient dependence on the surface temperature in the area ± 150 mm around a single row of nozzles.

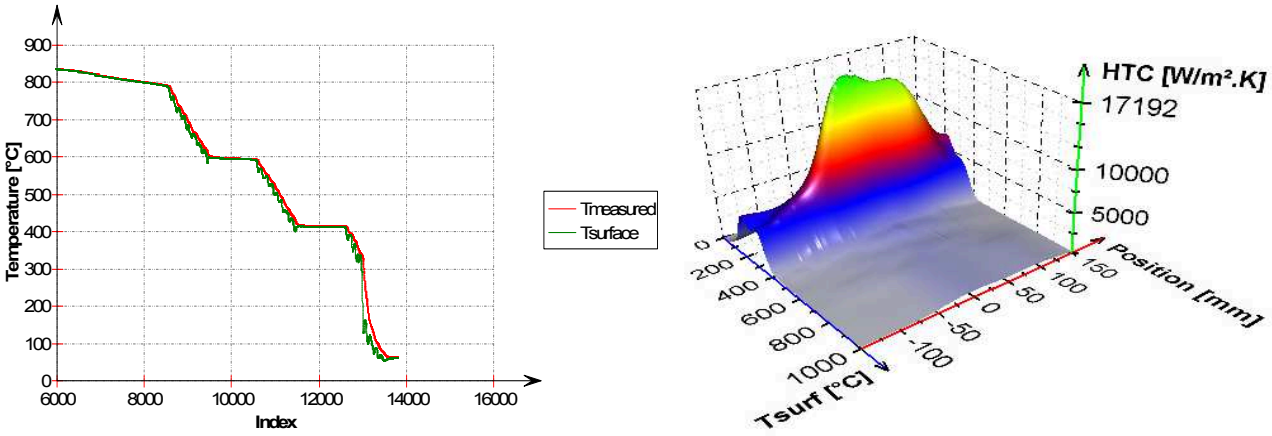

Fig. 2 Example of difference between measured temperature and computed surface temperature (on the left), computed heat transfer coefficient dependence on the surface temperature and position of sheet in cooling section, zero represents the center of the single row of nozzles.

The Influence of Various Parameters on the Heat Transfer Coefficient

The influence of five parameters on the cooling intensity was tested. The first parameter was water pressure. It was tested in a range from one to five bar. The heat transfer coefficient increases with increasing water pressure (Fig. 3 on the right). It is caused by the higher kinetic energy for higher water pressures. Very interesting results were obtained for the second tested parameter. It was found out the water temperature has a significant influence on the Leidenfrost temperature. Increase of the water temperature of 60°C caused the decrease of Leidenfrost point by 200°C. This finding can explain some problems with cooling during different seasons.

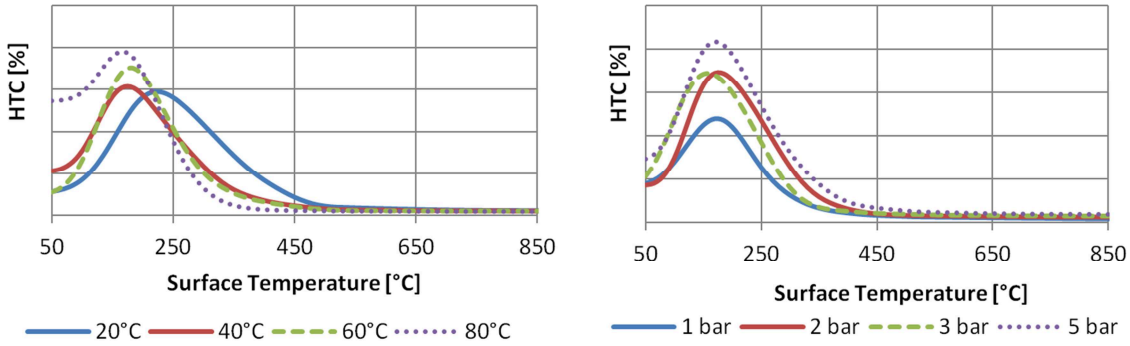

Fig. 3 Example of influence of water temperature on the heat transfer coefficient (HTC) (on the left) and dependence of heat transfer coefficient on the surface temperature for different water pressures and flow rates.

Next tested parameters were strip velocity and surface orientation. For both parameters, it was found out that they have negligible influence on the heat transfer coefficient for tested conditions (Fig. 4).

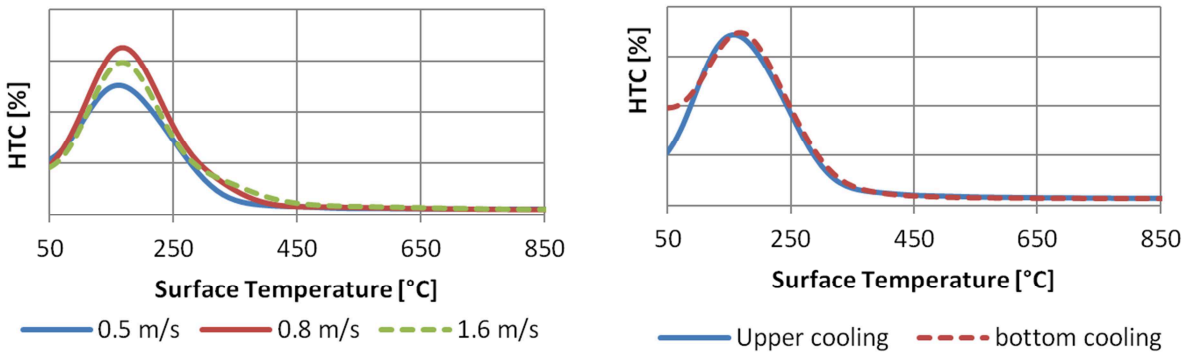

Fig. 4 Example of influence of strip movement velocity (on the left) and of the surface orientation (on the right) on the heat transfer coefficient

The last tested parameter was a nozzle span. This parameter was tested for optimization of the cooling section with respect to the homogeneity. The non-homogeneity of cooling was increased with increasing nozzle span.

Simulation and Cooling Section Sizing

Fives Stein used the curves of measured heat transfer coefficients depending on the surface temperature to size and to design its cooling section for stainless steel annealing. Fives Stein has made a measurements campaign on an industrial plant to compare laboratory measurements and plant measurements. It appeared that these measurements are in good agreement.

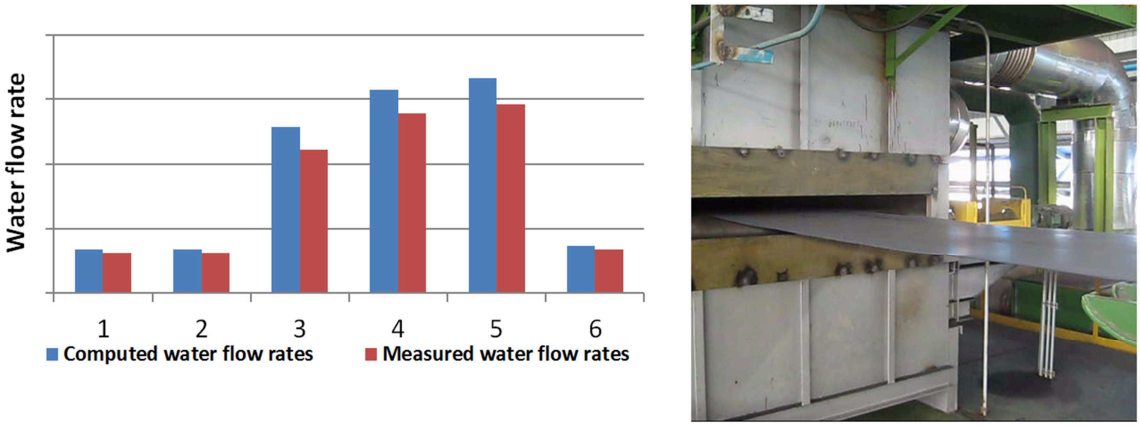

Fig. 5 Differences between predicted and measured flow rates which are necessary to cool down the strip for various cooling sections (on the left) and picture of the strip after annealing

Conclusion

The Fives stein company had to design a new cooling section for heat treatment of stainless steel. The sheet is heated to 1150 °C and cooled until ambient temperature. High cooling rates are required to produce the stainless steel to avoid the precipitation of carbides. The cooling intensity is essential information for designing cooling sections. Laboratory measurements are very important to obtain heat transfer coefficient. Heat Transfer and Fluid Flow Laboratory is fully equipped to test influence of different parameters on the cooling intensity. They were water pressure (water flow rate), water temperature, strip velocity and surface orientation (bottom and upper cooling). It was found out that water pressure has a significant influence on the cooling intensity. Increasing water pressure increases also the kinetic energy of droplets and also heat transfer coefficient. Second tested parameter was water temperature. It was found out a very interesting result that the water temperature

has a significant influence on the heat transfer coefficient. Increasing water temperature decreases the Leidenfrost temperature. Last two tested parameters were the velocity of moving strip and different surface orientations. These two parameters did not influenced heat transfer coefficient significantly for tested conditions. Obtained results were used by Fives stein company for sizing a cooling section with respect to required high cooling rates, homogenous cooling and low consumption of water. The cooling section was mounted in a real annealing line and a measurements campaign has been done on the real annealing line. This measurements campaign gave a very good result. The maximum difference between computed and measured flow rates which are necessary to cool down the strip was 15%. It is a great result in the field of a very complicated problem such as heat treatment.

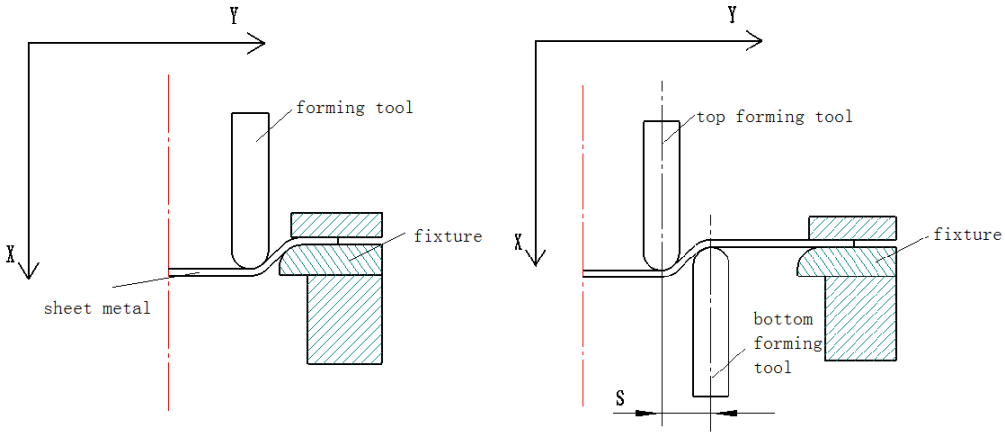
Keywords: Two point incremental forming; Tool-path; Forming accuracy

Abstract. Two point incremental forming is proposed to form the thin sheet into the desired shape in this paper. The forming accuracy of two point incremental forming is compared with single point incremental forming for Aluminum 1060. Then the forming accuracy is measured by FARO three coordinates measuring instrument. And a new method is proposed to analyze forming accuracy quantificationally. The experimental results show that the forming accuracy of two point incremental forming is obviously higher than single point incremental forming.



Introduction

The sheet metal incremental forming technology is based on layered progressive plastic deformation. Through the accumulation of plastic deformation, the shape of the component will be made. Following the development of sheet metal incremental forming technology, it is applied for different kinds of industrial production. Because of the characteristics of dieless forming, programmable control and flexible manufacturing, it has been gradually applied to some parts of small batch production [1]. Compared with the traditional sheet metal forming technology, it does not need special design die. The product development cycle will be shortened by using this technology. A lot of research subjects is studied, such as forming equipment, forming mechanism, forming process, tool-path.

Compared with single point incremental forming, the forming accuracy of two point incremental forming was quantificationally studied by experiment study. Before the experiment, the tool-path, the measuring method and the date analysis was prepared.

The Principle of Incremental Forming and the Forming Equipment

The principle of incremental forming includes single point incremental forming (SPIF) and two point incremental forming (TPIF). The equipment is spacial for sheet metal incremental forming.

(a) SPIF (b) TPIF

Fig.1 The Principle of Incremental Forming

Fig.1 (a) schematically presents the structure of single point incremental forming. The structure is very simple , including a machine, which can control the tool-path of the forming tool, a fixture and a forming tool [2]. The fixture is used to fix the sheet metal and define the processing area. The forming tool has no blade and the shape of the head is hemispherical. The plastic deformation will be accumulated by the forming tool working along the tool-path. Finally the shape of the sample will be made.

Fig.1 (b) schematically presents the structure of two point incremental forming [3]. Compared with the structure of single point incremental forming, the structure of two point incremental forming has two forming tools, including top forming tool and bottom forming tool. The top forming tool is used to form the sheet and the bottom forming tool is used to support the sheet. There is a predetermined distance between two of them. Two forming tools are controlled separately [4]. Through numerical control programming, two forming tools have different tool-paths. But the tool-path of the bottom forming tool follows the tool-path of the top forming tool [5].

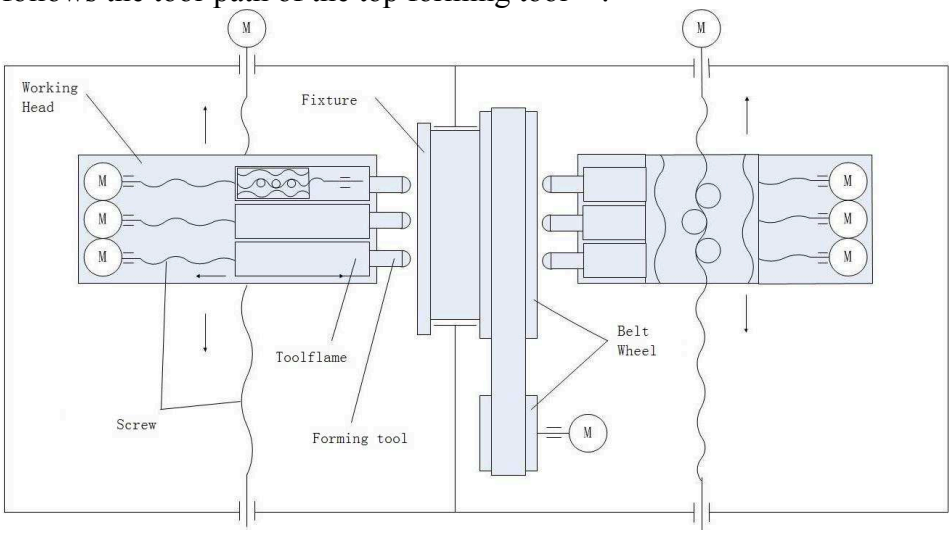


Fig.2 The Schematic Diagram of Sheet Metal Incremental Forming Equipment

This equipment is specially designed for the experiment of sheet metal incremental forming. Both of SPIF and TPIF can be done by this machine. Fig.2 presents the schematic diagram of this equipment. There are two working heads on each side. Through the screw, the working head is controlled by servo motor. There are three forming tools on each working head. All of them are controlled by servo motor, through the screw. The fixture is fixed on the rolling bearings. So the fixture can rotate and the power is supported by servo motor, through the bell wheel [6].

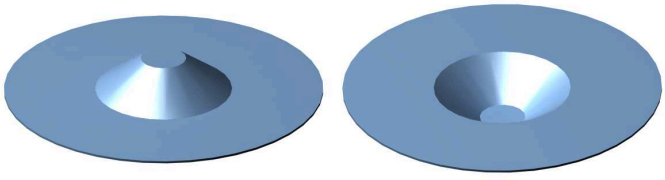

Fig.3 The Schematic Diagram of the Designed Geometry

The Designed Geometry and Tool-Path

Before the experiment, a designed geometry should be determined. Then, based on the designed geometry, the tool-path can be determined. Aluminum 1060 is chosen as sample material, diameter $D = 160mm$, thickness $T = 1mm$.

The designed geometry is determined by two requirements: (1) Because the forming limit will not be studied in this paper, forming angle should be lower than the forming limit. (2)The forming angle also should not be too low, otherwise the result of the experiment would not be obvious.

Above the two requirement, after referring to a lot of the reference on forming limit, the designed geometry is determined as Fig.3: the top diameter is 60mm, the bottom diameter is 2omm, the depth is 15mm and the forming angle is 53.2° .

About the tool-path of SPIF, the conventional contour line and out-to-in tool-path is chosen. Fig.4 (a) schematically presents the too-path of SPIF. The feeding in every step is smaller than 1mm to ensure the surface quality. Based on the designed geometry ,the feeding is determined: $\Delta X = 0.75mm$, $\Delta Y = 1mm$. After 20 step, the forming consequence is completed.

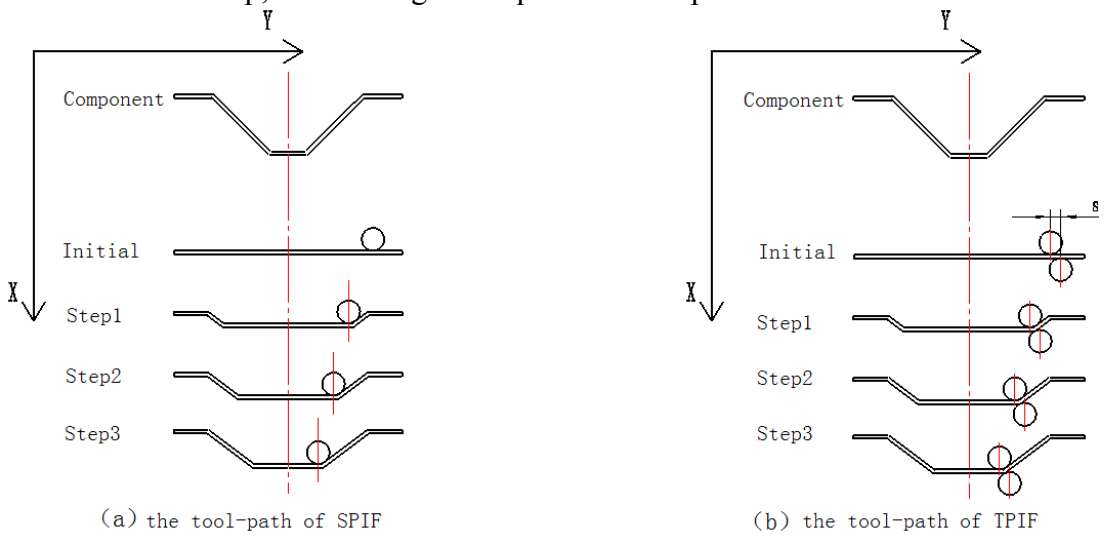

Fig.4 The Tool-path of SPIF and TPIF

About the tool-path of TPIF, the same as SPIF, the conventional contour line and out-to-in tool-path is chosen too. Fig.4 (b) schematically presents the too-path of TPIF. The tool-path of bottom tool is determined by the tool-path of top tool, but the feeding in each step is in common except for the first step. Based on the designed geometry ,the feeding is determined: $\Delta X = 0.75mm$, $\Delta Y = 1mm$. After 20 step, the forming consequence is completed [7].

Experiment and Results

Based on the tool-path, CNC Programming was completed and the sample was made by the equipment. Fig.5 presents the pictures of the samples.

Fig.5 The Formed Samples

The coordinates of the discrete points on the generatrix were measured by FARO three coordinates measuring instrument. The steps are as follows: (1) Clear the surface strains and spray imaging agent. (2) Scan the component by FARO three coordinates measuring instrument. (3) Based on geometric projection principle, the geometry of the generatrix was obtained on CATIA. (4) Obtain the coordinates of the discrete points on MATLAB. (5) Draw the curve on the origin.

Three parameters were presented to analyze the date quantificationally: Δ_{max}, $\varepsilon_{0.5\sim1}$, ε_1. Fig.6 presents comparison of designed geometry with practical geometry. In this graph, 70 points were picked on the curve, and the coordinates were (-1, y_1), (-2, y_2), (-3, y_3)... (k , y_k)... (-70, y_{70}),

$k=-1,-2,-3...-70$. The corresponding points on the designed geometry were (-1，Y_1), (-2,Y_2), (-3,Y_3)... (-k,Y_k)... (-70,Y_{70}). So the springback in each point was

$$\Delta_k = \left| y_k - Y_k \right| \tag{1}$$

When $x=-30mm$, the springback was max. So three parameters could be presented as

$$\Delta_{\max} = \left| y_{-30} - Y_{-30} \right| \tag{2}$$

$$\varepsilon_{0.5\sim1} = \frac{\sum(0.5mm \le \Delta_k < 1mm)}{70} \tag{3}$$

$$\varepsilon_1 = \frac{\sum(\Delta_k > 1mm)}{70} \tag{4}$$

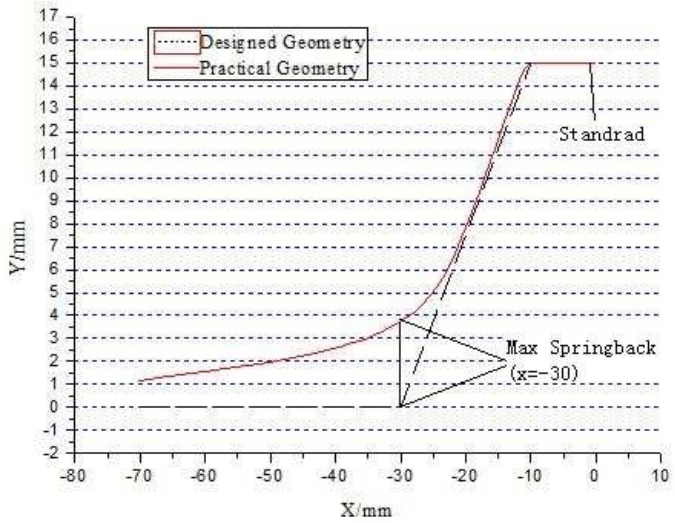

Fig.6 Comparison of Designed Geometry with Practical Geometry

Fig.7 presents comparison of the practical geometries from SPIF and TPIF with the designed geometry. Based on the formulas (1~4), three parameters were obtained in Table 1. The maximum springback of SPIF was 2.58mm, higher than TPIF. The $\varepsilon_{0.5\sim1}$ of SPIF was 5.7%, more than TPIF. And the ε_1 of SPIF was 48.6%, more than TPIF.

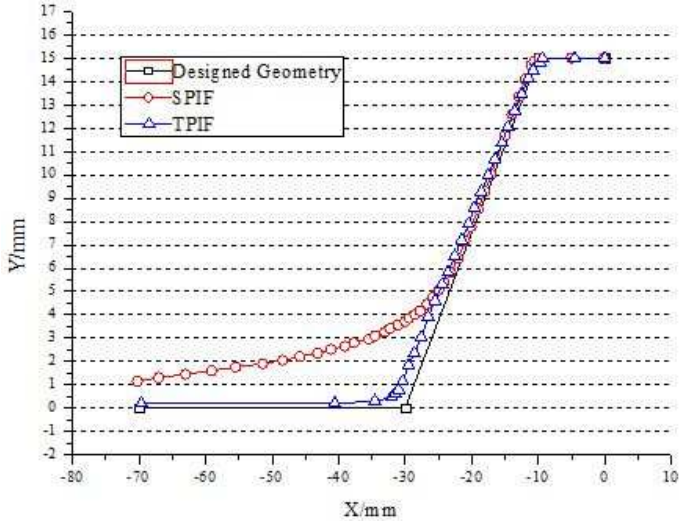

Fig.7 Comparison of the Practical Geometries from SPIF and TPIF with the Designed Geometry

TABLE 1 THE PARAMETERS OF SPIF AND TPIF

	SPIF	TPIF
Δ_{max}	3.71mm	1.13mm
$\varepsilon_{0.5\sim1}$	2.9%	8.6%
ε_1	65.7%	17.1%
$\varepsilon_{0.5\sim1}+\varepsilon_1$	68.6%	25.7%

Conclusions

This paper compared the forming accuracy of TPIF with SPIF quantificationally. A kind of method for measurement and analysis was presented. The experimental result shows that with the same process parameters, the forming accuracy of two point incremental forming is obviously higher than single point incremental forming.

In the future work, the influence of tool-path in TPIF on geometric accuracy and the influence of feeding on surface accuracy will be researched.

Keywords: Servo control system, Fuzzy PI, ACPTFM, Mechanical press

Abstract. A control method for servo control system of Assembled Claw Pole Stator Transverse Flux Machine(ACPTFM) by controlling the armature current Root-Mean-Square (RMS) and the angle between armature current and no-load EMF is proposed in this paper. The servo control system of ACPTFM is composed of a series of closed-loop controllers, and the most complexity design of speed controller is described in detail. Fuzzy adaptive PI control method which integrates the advantages of fuzzy control and PI control is adopted to design the speed controller. Experimental results show that it can improve the system dynamic response and steady state accuracy.

Introduction

Comparing with the conventional mechanical press, mechanical press driven by AC servo motor is hailed as the third-generation mechanical press,which has the advantages of simple structure, high quality of product, good flexibility of slider movement, energy saving and noise reduction[1]. The performance of the servo mechanical press depends on the high performance of servo motor, which must be able to achieve low speed, high torque operation and have wide speed range. Transverse flux machine can meet the requirements quite well due to its special structure[2,3]. However, the effective servo control system and its control strategy of TFM has not been fully researched and discussed in this field.

In this paper, the Assembled Claw Pole Stator Transverse Flux Machine(ACPTFM)[4] is applied to servo press JS21-36 as its power plant, innovatively. Based on the analysis of ACPTFM electrical characteristics the servo control system is designed. The control method for speed loop is the main subject in this paper. Because fuzzy control has better robustness, meanwhile PI control can speed up the dynamic response and eliminate the steady-state error. So combine the advantages of both control methods, using fuzzy adaptive PI control strategy to design the speed loop in servo control system. Experimental results show that the servo control system and the control strategy is feasible to establish.

Servo Control System of ACPTFM

Servo system is one of the automatic control system, it generally takes mechanical position(angle) or speed as the controlled object. The main task of servo control system is let the position(angle) or speed commands quickly and accurately achieved by executive mechanism. In this way, the system can automatically, continuously and accurately reproduce the input changes of the given. Servo control system is usually a closed-loop control system with negative feedback. For the motor servo control system, it takes the rotor angle and speed as the controlled object, including the controllers and detection devices.

In this paper, the researcher creatively uses ACPTFM as the drive of the mechanical press. The single-phase average electromagnetic torque of ACPTFM is expressed as

$$\mathrm{T_m} = p[\psi_f I\cos\varepsilon + \frac{1}{2}(L_q - L_d)I^2\sin 2\varepsilon]. \quad (1)$$

where p, L_q and L_d are the number of pole pairs, cross-axis inductance and direct-axis inductance respectively. I, ε and Ψ_f are the armature current, the angle between armature current and no-load EMF (armature current initial phase) and the flux produced by permanent magnet. After the motor have been produced, the permanent magnet flux linkage Ψ_f is a constant. Within the rated current the quadrature-axis inductance L_q and direct-axis inductance L_d can also be regarded as constants. So, actually, the torque control of ACPTFM is the controlling of the armature current Root-Mean-Square (RMS) and the angle between armature current and no-load EMF. After researched the electrical characteristics of the ACPTFM, the servo control system of ACPTFM is designed. Fig.1 shows the system chart.

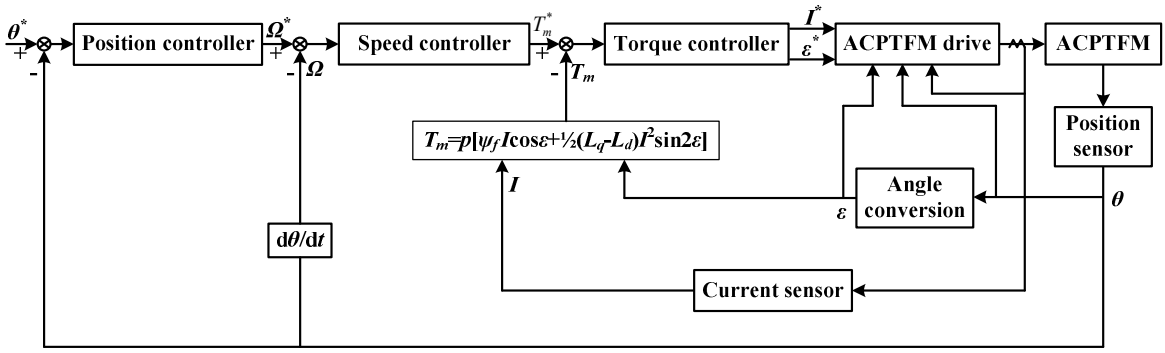

Fig.1 Servo Control System of ACPTFM

In Fig.1, θ and Ω represent the ACPTFM angle spatial displacement and angular speed. In order to control the armature current initial phase ε, change the ACPTFM angle spatial displacement θ into actual current initial phase by angle conversion. I presents the RMS of armature current. The servo control system of ACPTFM use a series of four closed-loop to achieve the controlling task which is the control of the ACPTFM position, speed, torque and current, and the current loop is included in the internal of drive. The signal flow is as follow: the input signal of position controller is the difference value of rotor position given value subtract its actual value, the output signal of position controller subtracts the actual speed value and the result uses as the given signal of speed controller. Then the speed controller's output is as the given signal of the torque controller. The practical torque value can be acquired by Eq.1. The difference value which the torque given value subtracts the actual torque value inputs into the torque controller, after computing, the RMS of single phase armature current and the given signal of initial current phase are gotten, thus, the sinusoidal signal of armature current can be acquired. Consequently, input the signal into the ACPTFM drive as the current given. Finally, through the current loop and a series of calculation processing, the ACPTFM drive outputs the actual armature current, so as to achieve controlling of the machine.

Control Strategy of Servo Control System of ACPTFM

The servo control system of mechanical press can take slider position as its control object, but the whole system from servo motor to slider exist nonlinear and inertial seriously, so the design of entirety closed-loop position controller is very difficult. Often needs to add a lot of compensation control strategies, but the result still does not meet the accuracy requirement. On the other hand, there are many detection taches in the system, it needs plenty of time to handle the detection and sampling, and the complex algorithms of position controller also need time to run. Because of the serious delay of the system, the real time performance of this kind control system needs to be considered.

Researches have studied the kinetic characteristic of mechanical press and built its mathematical model of Bezier curve. The process characteristic parameters of crank input and slider output have gotten as well. In this paper, these characteristic parameters are applied to the servo control system of mechanical press, which will greatly simplify the entire control system and the rapidity of system will be improved to a great extent.

In the mechanical press driven by ACPTFM, the motor output drives the slider movement through some intermediate synchronous conversion links, directly. The Bezier curve mathematical model of the process for servo mechanical press is already known, which determines the input of the servo control system of ACPTFM. In the servo control system, control strategy is the main issue. Wherein the functional relationship between input and output of the position controller and the torque controller is clear, not described in detail here. A simple incremental PI regulator can be added to meet the control requirements. But for the speed controller, the input is speed value and the output is torque value, because of the frequent change of load torque and the relationship between speed and torque is complex, moreover, the inconsistency of the workpiece, it is prone to large disturbance. By the previous analysis, the range of motor speed requirement for position servo control is relatively wide and have higher demands on the accuracy of response curve. Therefor, simple PID speed controller cannot meet the requirements of control.

Currently, the fuzzy control is a more mature intelligent control strategy, the control characteristics of which is change the expert knowledge and experience into language control rules. And use these rules to control the system, so fuzzy control has strong robustness. However, compared with traditional PID control, fuzzy control has some shortcomings and deficiencies. For example, the control action is less delicate, the stability of system is less precision and the system is under the influence of the subjective. In addition, fuzzy control generally use two-dimensional structure, in this case, using speed deviation e and the rate of change e_c as input variables. This two-dimensional fuzzy controller has a similar role like the conventional PD controller, it can obtain good dynamic characteristics, but its stability is poor. And consider the function of PI controller, the proportional control accelerates the dynamic response speed; the integral control eliminates static errors but the dynamic response is slow. The combination of fuzzy control and PI control strategy can compensate the shortcomings of each other, this will enhance the control system dynamic and static performance. In this article, the speed controller uses fuzzy adaptive PI control method as its control strategy. This method combines the fuzzy logic control and adaptive strategies together, it is able to get a good control effect.

Fig.2 shows the block diagram of fuzzy adaptive PI speed controller. Fuzzy variables E and E_c are the fuzzy output, then through fuzzy reasoning and defuzzification acquire correction value which can adjust the parameters of PI controller. With the motor running state changes, parameter P and I in the PI controller are changing as well, so good dynamic and static control effect can be obtained.

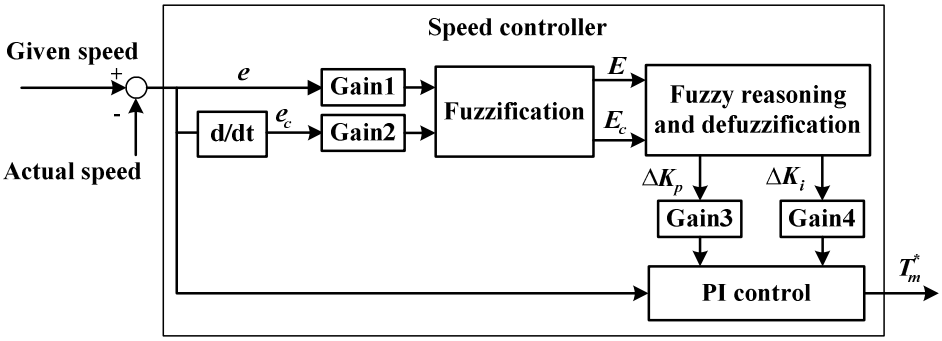

Fig.2 Speed Controller of ACPTFM

Fuzzy reasoning calculation bases on the experience and expertise, it needs to define the language variable. This article defines the variable range of language as follow: positive largest (PL), positive middle (PM), positive small (PS), zero (ZO), negative small (NS), negative medium (NM) and negative largest (NL). Seven triangular membership functions are used to definite the input and output variables, the range of the abscissa of membership function is (-1,1), and the input and output using the same membership function. The amplitude of input and output variables are controlled by adjusting their switches Gain1, Gain2, Gain3 and Gain4.

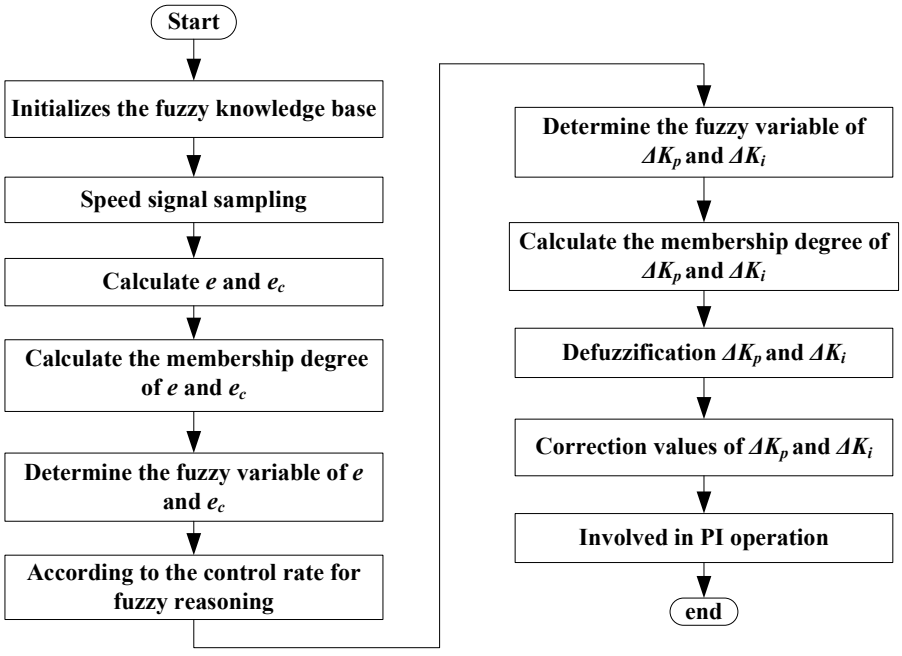
The fuzzy controller uses fuzzy language control rate to describe the control features, the fuzzy control rate is a set of language-based rules, it is a refined process of forming human reasoning and

inference knowledge. Fuzzy control rate, membership function and reasoning method determine the transfer characteristics of fuzzy controller, they also are called the transfer function. When establish the fuzzy control rate its integrity should be ensured, which means all input states need to be covered, so under each of the input state system has a corresponding control rule to work. According to the actual situation of speed controller in servo control system of ACPTFM, the fuzzy control rate of the speed controller is as shown in Table 1.

TABLE 1 FUZZY CONTROL RULE

		deviation e						
		NL	NM	NS	ZO	PS	PM	PL
Deviation rate of change e_c	NL	NL	NL	NL	NL	NM	NS	ZO
	NM	NL	NL	NM	NM	NS	ZO	PS
	NS	NL	NM	NM	NS	ZO	PS	PM
	ZO	NL	NM	NS	ZO	PS	PM	PL
	PS	NM	NS	ZO	PS	PM	PM	PL
	PM	NS	ZO	PS	PM	PM	PL	PL
	PL	ZO	PS	PM	PL	PL	PL	PL

Fig.3 shows the flow diagram of adaptive fuzzy PI control system. From the controlling flow start, the knowledge base of fuzzy control is initialized firstly. The initialization includes the determination of fuzzy control rates and membership functions. Secondly, the speed deviation e and the deviation rate of change e_c and their membership are calculated. Fuzzy reasoning usually uses the minimum and maximum method and defuzzification adopts the area of the center of gravity method. Finally, the output parameters and participate are fixed in PI controller operation.



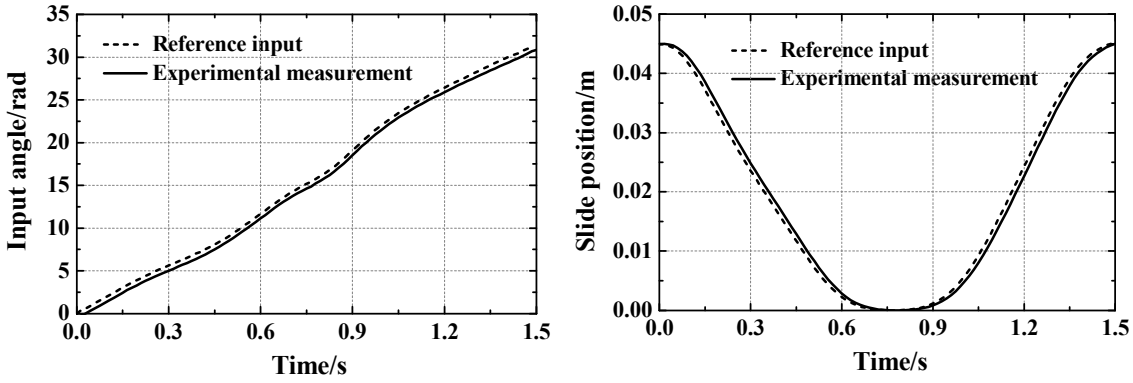


Fig.3 The flow diagram of adaptive fuzzy PI control system

Results and Discussion

The test results of the drawing process movement characteristics are shown in Fig.4. It can be seen that the servo mechanical press operation characteristic curve (reference input) of experiment and optimized are the same. In Fig.4(a), the motor input angle curve shows that the change of motor angle is non uniform. This is a servo operation status, which is to meet the requirements of drawing process

in press. Fig.4(b) shows that within the design range of the drawing processing of 0.03~0.01mm, the displacement curve is nearly a straight line. This will ensure a good processing quality of drawing process. The servo operation status illustrate that within the drawing processing interval, the motor is running at rated speed. This interval is the constant torque operation of motor which means low speed, high torque range, and motor outputs rate torque. Without the drawing processing interval, the motor is working above the rate speed, which is the constant power range.

(a) (b)

Fig.4 Experimental Results of Drawing Process Under Servo Control. (a) Input Angle. (b) Slider Position

Conclusions

In this paper, the servo control system of ACPTFM is established and its control strategy is discussed. Particularly, the control strategy of speed loop is presented. Because the rapidity, accuracy and stability of fuzzy adaptive PI control system is better than the traditional control method, the speed loop uses fuzzy adaptive PI control strategy as its control method. The fuzzy control rules are established and they cover all input states effectively. Based on the analysis of speed loop, a flow diagram of fuzzy adaptive PI control system is presented. The slide position output curves show that the servo control system based on fuzzy adaptive PI control method is effective to achieve high performance for the press.

Keywords: Friction stir welding, Dissimilar barrier butt joints, AA2024, AA6061/SiC/55p composite, Microstructure, Mechanical properties

Abstract. Dissimilar barrier butt joints of AA2024 to AA6061/SiC/55p composite were fabricated by friction stir welding. Effect of the traverse speed on interface bonding, joint microstructure and tensile properties was investigated. Results revealed that, all joints possessed a tensile strength stronger than 80% that of the composite base materials, and the highest strength value was 178MPa. Macro interface can be readily identified in the weld zone between AA2024 and AA6061/SiC/55p composite, of which the area decreased and then increased as the traverse speed increased. The size and shape of SiC particles in the interface zone varied a lot due to different stirring effect and forward impact of the pin in different traverse speeds. Increasingly impairment of the composite base material near the interface was also detected with the traverse speed increasing.

Introduction

Aluminum alloys and SiC particles reinforced aluminum matrix composites (AMCs) are widely applied in aerospace, automotive and many other applications due to their superior physical and mechanical properties[1-3]. Among them, AMCs with high volume SiC particles, possessed higher thermal conductivity, lower thermal expansion coefficients and well wear resistance, has been an important material for some components in recent years[4,5]. However, application of AMCs with high volume SiC particles is limited for its poor weldability and high cost[6,7], which illuminates its joining to aluminum alloys. Nonetheless, due to the presence of SiC particles, it is difficult to join AMCs by using conventional fusion welding techniques[8-10], which always give rise to defects such as voids and cracks and deleterious chemical reactions of aluminum matrix with the reinforcement particles.

As a relatively novel solid-state joining process, friction stir welding (FSW) was invented by TWI in 1990s[11], and shows a great capability to join aluminum alloys and dissimilar materials[12-15]. It is also considered as one desirable joining method for AMCs because of no material melting in the process and so avoiding the presence of voids and other defects[16-18]. Xiao et al[19] investigated the FSW of AA2009/SiC/15p composites to AA2024 and examined the microstructure and mechanical properties of the joints. They found that complicated microstructure evolution occurred in the weld nugget zone during welding and the ultimate tensile strength of the joint was 85% that of AA2024 base materials. NASA [20]also studied the feasibility of FSW of AMCs with 50vol.% SiC particles to AA2195 and found that the pin broke off after only 38mm of weld and concluded the two materials can not be joined by FSW. As many difficulties have been encountered in joining similar or dissimilar AMCs with high volume SiC particles, researches on it are very limited[21,22].

In this study, an attempt was made to join 2mm thick AMCs with 55vol.% SiC particles and AA2024 using FSW and investigation on the influence of the traverse speed on the microstructure and tensile properties of the dissimilar joints was also studied.

Experimental Procedure

AA6061/SiC/55p AMCs plates produced by non-pressure infiltration methods and extruded plates of AA2024 in a T4 temper condition were used in this study. The nominal median particle size of silicon carbide in the AMCs is 40μm and the matrix is a standard AA6061. The chemical composition of the AA2024 extruded plate and composite matrix AA6061 are given in Table 1. A h-13 tool with a concave shoulder 19mm in diameter and an unthreaded tapered cylindrical pin 6mm in diameter and 3mm in length with a spherical tip was used.

TABLE 1. CHEMICAL COMPOSITION OF AA2024 AND AA6061 (WT.%).

Materials	Si	Fe	Cu	Mn	Mg	Cr	Zn	Ti	Al
AA2024	0.5	0.5	3.9	0.6	1.6	0.10	0.25	0.15	Bal.
AA6061	0.48	0.7	0.25	0.15	1.0	0.25	0.25	0.15	Bal.

The weld assembly is shown in Fig. 1, where AMCs with 100mm in length and 50mm in width is placed on the advancing side of the weld, and the butted AA2024 is on the retreating side with the same size as the AMC plates. A barrier, having the same constitution and heat treated condition as the composite matrix, is placed on the butt joint to avoid wear of tool shoulder, with a length of 90mm, width 80mm and thickness 0.8mm. Also a back plate, as same as the barrier, is used to avoid insufficient joining near the bottom of the butted plates. Aiming at reducing the pin wear and enlarging the plastic zone size of the weld, pin-offset of 1.5mm to AA2024 side was also employed.

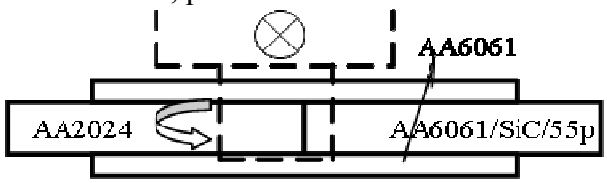

Fig. 1. Schematic of the Welding Process

All plates were carefully degreased with liquid acetone and air dried. A steel brush was used on the plate and its edges to remove residual smudges and oxide films before the actual welding. The rotational speed was set 750rpm, and the traverse speed was varied from 10mm·min^{-1} to 80 mm·min^{-1} in the welding process.

After FSW, the specimens were cross-sectioned perpendicular to the weld direction for microstructural examination and were prepared by mechanical grinding, polishing and etching using Keller's reagent. The microstructures were examined using optical microscopy(OM, Observer10) and scanning electron microscopy(SEM, Hitachi-S4800). After the barrier and the back-plate alloy being milled away, tensile tests were carried out at a test speed of 1 mm·min^{-1} at room temperature, and three specimens were tested for each group. The fracture surfaces were then examined using SEM.

Results and Discussion

Macroscopic Structure

Fig. 2 shows the macroscopic images of dissimilar joints produced in different traverse speeds. It was observed that sound welds can be obtained for all the welding conditions investigated. A macro interface between the AMC and AA2024 can be readily identified. It is evident that the two materials were not completely blended for all four welding conditions. This can be attributed to the unthreaded feature of the FSW tool designed to reduce the tool wear. It was reported[23]that the macro- interface can also be easily identified in dissimilar FSW of AA6063 alloy and B_4C/Al MMC when using a cylindrical tool with no threads, which is similar to the results in the present study. It was also

observed that FSW tools without threads could not fully mix the materials macroscopically because the materials experienced a weak vertical flow movement[24,25].

As the traverse speed increased from 10 mm·min^{-1} to 40 mm·min^{-1}, the contour of the macro-interface changed a little, but all possessed a feature of a relatively smooth and moderate transition from the upper to the lower side of the interface, as shown in Fig. 2(a) to Fig. 2(c). When the traverse speed increased to 80 mm·min^{-1}, the macro-interface became sharper in transition, which may result in a weaker load-transfer near the interface and a higher stress-concentration. Because its segregation from the interface can be detected in magnified views, the composite material adjacent to the top of the macro-interface in Fig. 2(b) was not taken as part of the contour.

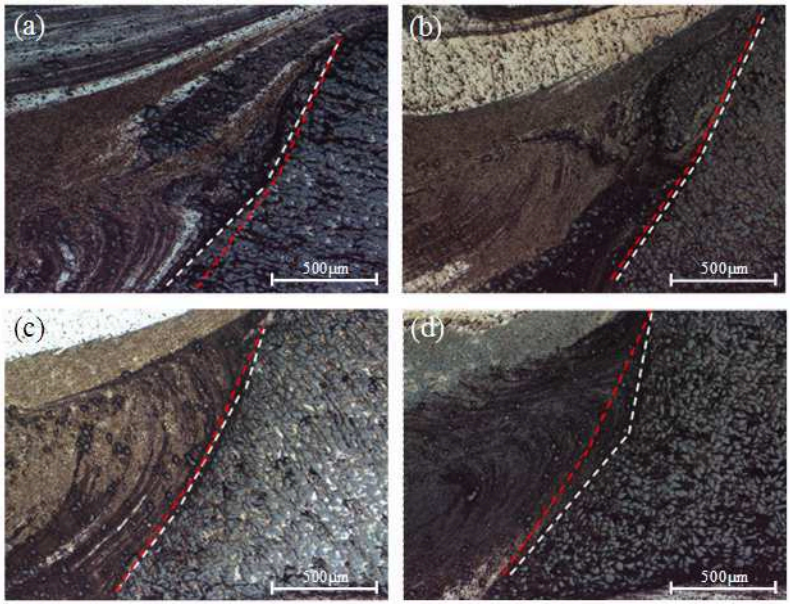

Fig. 2. Macrographs Of Welds In Traverse Speed Of (a) 10 mm·min^{-1}, (b) 20 mm·min^{-1}, (c) 40 mm·min^{-1} and (d) 80 mm·min^{-1}.

To facilitate discussion, the macro-interface contour in 20 mm·min^{-1} was used as a reference, and was painted red. It can be seen that the slope of upper side of the interface in 10 mm·min^{-1} is similar to that of the reference, while slope of the lower side is a little smaller, so a larger interface area in 10 mm·min^{-1} can be concluded. And the overall slope of the interface in 20 mm·min^{-1} and that in 40 mm·min^{-1} are similar, suggesting their interface areas are nearly the same. When the traverse speed increased to 80 mm·min^{-1}, the interface area increased again with a lower slope compared to that of 20 mm·min^{-1}. This may be explained by a higher traverse speed induced stronger impact of the pin to the composite material. Furthermore, the higher traverse speed caused a lower heat input which reduced the tendency of the composite materials to be plastically deformed[26,27].

Microstructure Characteristics

Fig. 3 shows the SEM microstructures of the joint interface and composite base material (CBM) adjacent to it. As can be seen, when the traverse speed is 10 mm·min^{-1}, particles in small sizes, with blunt edges, can be found in the interface zone, which indicates the particles were refined as a result of the stirring effect of the tool pin in low traverse speed. Meanwhile, the CBM kept its original features due to a low impact to it of the pin in low traverse speed.

As the traverse speed increasing, the size of the SiC particles increased and their edges became sharper, probably leading to high stress-concentration around the sharp edges and cause crack initiation under load condition. However, when the traverse speed increases to 80 mm·min^{-1}, size of SiC particles became smaller again. This may result from the fact that the impact to the SiC particles from the pin and collisions between the particles themselves became more severe in higher traverse speed. However, it can be observed in Fig. 4 that impairment of the CBM became more severe and microcracks in it is much more. This may result from the stronger impact to the CBM and a lower plasticity due to lower heat input as the traverse speed increased.

Tensile Properties

The effect of the traverse speed on the tensile strength of the joints is depicted in Fig. 5. It is evident from the curve that the joints fabricated in 10 mm·min^{-1} of traverse speed exhibit the highest tensile strength, which is 178MPa and 98% of that of CBM. As the traverse speed increases, a decrease in tensile strength occurred, reaching a lowest tensile strength of 146MPa, i.e., 80.7% that of CBM, when the traverse speed is 80 mm·min^{-1}. Thus, all joints fabricated in range of 10 mm·min^{-1} to 80 mm·min^{-1} possessed a strength higher than 80% that of CBM, indicating that good joint strength can be obtained in such welding parameters. The fracture location of the joint is shown in Fig. 6 with the cross-section view inserted below. It can be seen that the joint failed in the interface of the two materials, implying it's the weakest part of the joint.

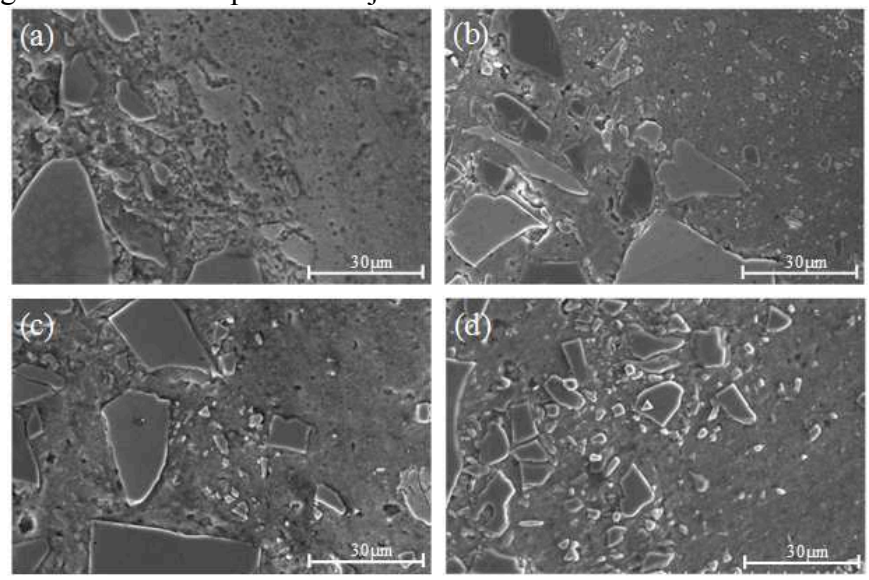

Fig. 3. Micrographs of the Joint Interfaces in Traverse Speed of (a) 10 mm·min^{-1}, (b) 20 mm·min^{-1}, (c) 40 mm·min^{-1} and (d) 80 mm·min^{-1}.

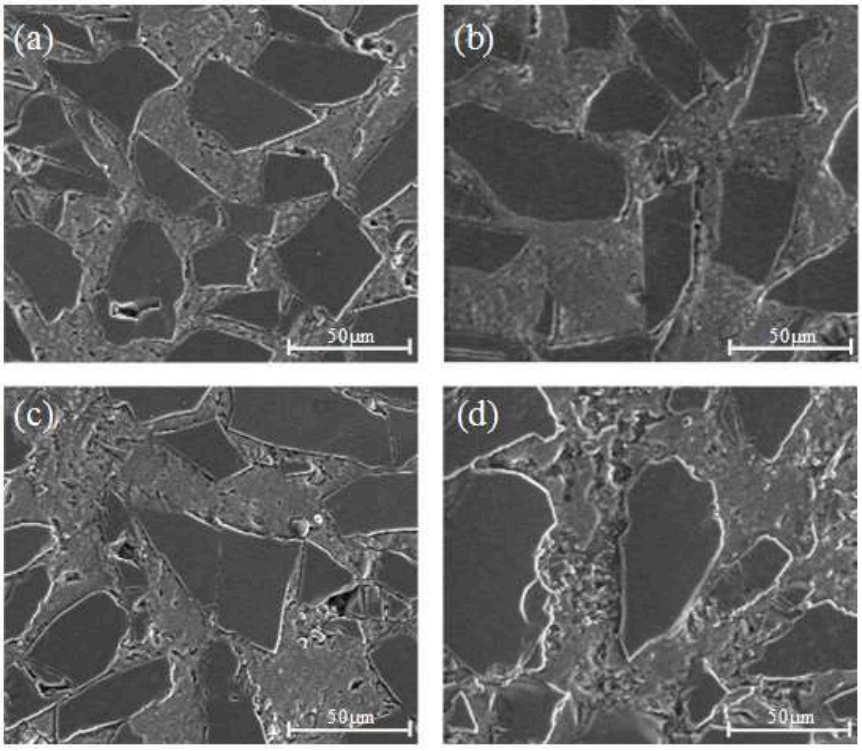

Fig. 4. Micrographs of the Composite Base Material Near The Joint Interface In Traverse Speed of (a) 10 mm·min^{-1}, (b) 20 mm·min^{-1}, (c) 40 mm·min^{-1} and (d) 80 mm·min^{-1}.

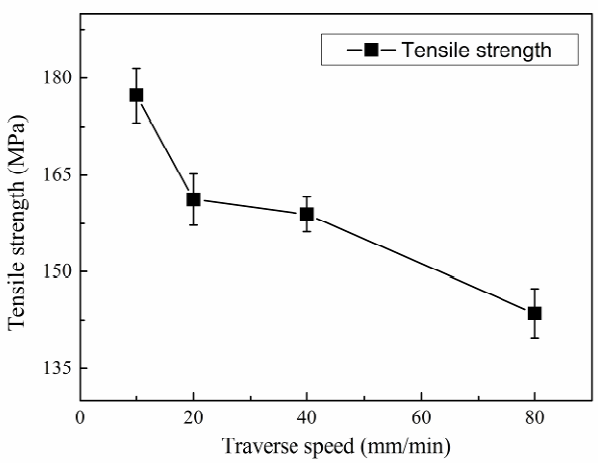

Fig. 5. Tensile Strength of the Joint in Different Traverse Speeds.

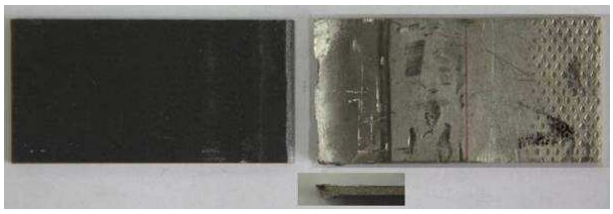

Fig. 6. Fracture Location of the Tested Specimen.

The factors which determine the tensile strength of the joints are: (i) presence of macroscopic defects in weld zone, (ii) impairment of the CBM adjacent to the interface, (iii) degree of plastic flow and amount of mixing of both materials, (iv) stress-concentration in interface deriving from sharp edges of the SiC particles. The defect-free joints can be achieved for all parameters, so all the joints experienced an intact macrostructures. Joints fabricated in 10 $mm \cdot min^{-1}$ yielded the highest tensile strength due to an relatively intact feature of CBM and intense plastic flow and mixing of the two materials, as well as the bluntness of SiC particles edges. In 20 $mm \cdot min^{-1}$ and 40 $mm \cdot min^{-1}$ the tensile strength of joints became lower as a result of insufficient mixing of the two materials and the sharp edges of ceramic particles in the interface zone. And in highest traverse speed of 80 $mm \cdot min^{-1}$, severe impairment took place on the CBM and finally reduced the tensile strength of the joint to a large extent.

The fracture surface, which is shown in Fig. 7, was characterized by some Al dimples and large amount of SiC particles, and microcracks were also observed. The Al dimples derived from fracture of the composite matrix are small and shallow. And the SiC particles in different size and shape all looks smooth. This may be explained by the fact that high stress-concentration was induced by the sharp edges of the particles, from which cracks initiated and propagated by the particles surfaces[28]. Thus, the failure mode is brittle domained brittle-ductile fracture, due to the segregation of SiC particles to composite matrix and fracture of composite matrix itself.

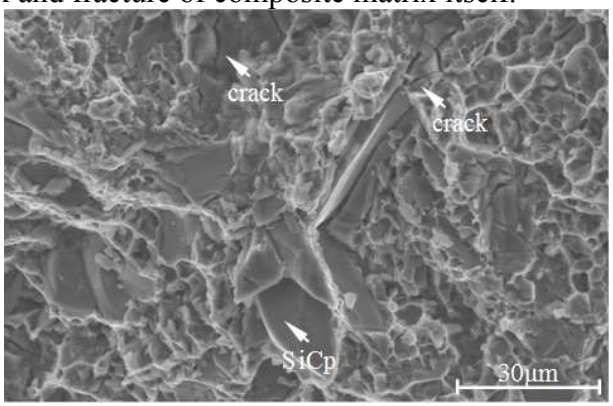

Fig. 7. Fractography of the Joint

Conclusions

In summary, the following conclusions are drawn:

1. Defect-free dissimilar barrier butt joints of 2mm thick AA2024 to AA6061/SiC/55p composite can be obtained under all welding conditions investigated.

2. With the increase of the traverse speed, the area of the interface increases first and then decreases, vise versa the size of the SiC particles in the interface zone, while impairment of the composite matrix near the interface increases all through. This may be a result of the reinforcement particles and the composite base material suffering stronger impact from the stirring pin and the material's lower plasticity in higher traverse speed.

3. The tensile strength of the joints decreases with the increasing of traverse speed. The highest tensile strength obtained is 178MPa with a 10 $mm \cdot min^{-1}$traverse speed, while the lowest is 146MPa when the traverse speed is 80 $mm \cdot min^{-1}$. All joints possessed a tensile strength higher than 80% that of the composite base material.

4. Failure mode of the joints is brittle domained brittle-ductile fracture, which is the result of the segregation of SiC particles to composite matrix and fracture of composite matrix itself.

Keywords: aluminum alloy bellows, semi-dieless metal bellows forming process, compression, local heating technique, bellows shape.

Abstract: The metal bellows are used in a large number of industrial applications for their flexile and elastic properties. For the traditional manufacturing methods for metal bellows, the dies and (or) tools are required. It is inconvenient to change the shape of metal bellows and also leads to the high cost. To reduce the manufacturing cost and produce the metal bellows with various shapes, the semi-dieless metal bellows forming process was proposed. The deformation behavior of aluminum alloy tube in semi-dieless bellows forming process was investigated in the study. The effects of compression ratio, heating length on the convolution height, pitch of bellows during the semi-dieless bellows forming process were studied. The results showed that the deformation conditions of semi-dieless forming process have significant influences on the shape of aluminum alloy bellows and deformation behavior of aluminum alloy tube in the forming process. The increase of compression ratio, heating temperature and heating length resulted in the increase of pitch and decrease convolution height of aluminum alloy metal bellows.

Introduction

Metal bellows are one kind of special tube whose wall with the convolution shape. The shape of convolution of the metal bellows can be changed easily by the external force along the axial direction of metal bellows. The expansion and shrinkage caused by heating and cooling, as well as mechanical vibrations can be absorbed by the metal bellows for their special properties [1]. The metal bellows are used in a large number of industrial applications for their airtight and elastic properties, such as piping systems, automotive industries, aerospace and micro-electromechanical systems etc. [2]. The metal bellows are divided into two main types - formed and welded. The formed metal bellows are produced by reworking tubes, with a variety of processes, including cold tube bulging [3], cold forming (rolling) [4], electroforming, hydroforming[5], combination process of bulging and upsetting [6] and gas bulging at elevated temperature [7]. This kind of metal bellows are also called convoluted bellows or sylphons.

To reduce the cost and manufacture the metal bellows with various shapes, the semi-dieless metal bellows forming process with local heating technique tube was proposed. For this new semi-dieless metal forming process, only the mandrel was used to prevent the bending and buckling of long tube due to the compressive force during the forming process. The metal bellows with a material of SUS 304 has been successfully manufactured with the new semi-dieless bellows forming process with local heating technique [2]. The forming process is easy to be realized with the tubular material which has a low thermal conductive coefficient because it is easy to control the length of heating zone. In the

present study, to confirm the applicability of the new semi-dieless bellows forming process with local heating technique for the tubular materials with high thermal conductive coefficient, the aluminum alloy tube was chosen to manufacture the bellows with the new method. The deformation behavior of aluminum alloy tube in the semi-dieless forming process was investigated. The effects of compression ratio, heating temperature and heating length on the convolution height, pitch of bellows and deformation behavior of aluminum alloy tube during the semi-dieless bellows forming process were studied. The results showed that the semi-dieless forming process with local heating techneque can be used to manufacture the metal bellows with tubular materials which have a high thermal conductive coefficient. The deformation conditions of semi-dieless forming process have significant influences on the shape of aluminum alloy bellows and deformation behavior of aluminum alloy tube in the forming process. The increase of compression ratio, heating temperature and heating length resulted in the increase of pitch and decrease convolution height of aluminum alloy metal bellows.

Material and Experimental Method

The Aluminum alloy (A6061) tubes with a dimension of 25(outside diameter) × 2 (wall thickness) ×800 (length) mm were used in the present study. It is known that at the action of compression force in the axial direction of tube, the axisymmetric buckling phenomenon will occur sequentially if there is a mandrel in the tube. In the current study, the continuous buckling phenomenon was used to manufacture the metal bellows. The principle of semi-dieless metal bellows forming process is given in Fig. 1. The experimental equipment was developed according to this principle. To control the location of the buckling appeared, the local heating technique and water cooling method were utilized. A high-frequency induction heating device was used to heat the metal tubes. The circulating water with a constant temperature of 20°C was used. The different heating temperatures of 300°C, 350°C, 400°C and 450°C were used to study the effect of heating temperature on the bellows shape and deformation behavior of aluminum alloy tube in the forming process. The compression ratios ($C=V_1/V_2$) of 1.3, 1.5, 1.6 and 1.7 were chosen.

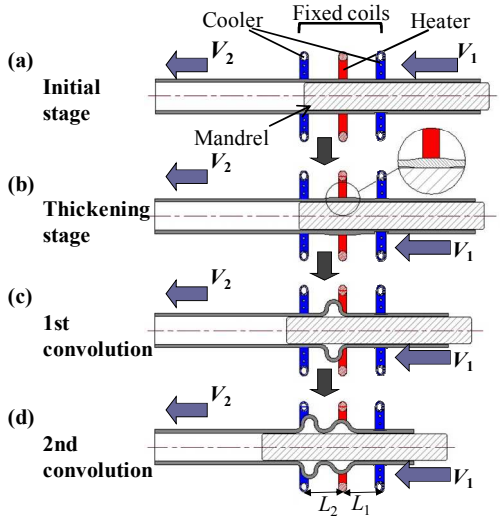

Fig. 1: Schematic illustration of principle of semi-dieless metal bellows forming process (a) initial stage (b) thickening stage (c) 1st convolution (d) 2nd convolution.

The semi-dieless forming process of the metal bellows can be divided into four stages. In the first stage, when the metal tube is heated to the certain temperature the drive plates start to move with different speeds of V_1 and V_2 ($V_1 > V_2$). In the second stage, at the compression force caused by the speed difference of tube ends, the heated part of tube started to deform and become thicker. With the continuous action of compression the first convolution was formed, as shown in Fig. 1(c). The water coiling was adjacent to the heating zone. The metal bellows was cooled by the water and then became hard enough to prevent the further deformation when the metal bellows moved to the cooling region.

So its shape was fixed by the cooling process. At the same time, the second convolution was formed, as shown in Fig. 1(d). The metal bellows were formed with the forming process continuing.

Results and Discussion

Forming process of aluminum alloy bellows. The aluminum alloy bellows with a uniform shape were successfully obtained by the semi-dieless forming process with local heating technique, as shown in Fig. 2. In the experiment, the forming process can be divided into two stages, initial stage and stable stage. In the present study, the two drive plates started to move when the tube was heated to a certain temperature accompanied by water cooling process in the initial stage. In this stage, the first convolution was formed due to the different speeds of the two drive plates. Because the water cooling was realized with two nozzles, the contact area between water and tube surface was changed when the tube started to move driven by the two drive plates. It resulted in the instability of convolution forming process in the initial stage. However, the instability can be alleviated by adjusting the initial heating temperature and cooling intensity. In the stable stage, the convolutions were formed continuously as the stable heating and cooling processes. The shapes of the convolutions which formed in the stable stage are the same.

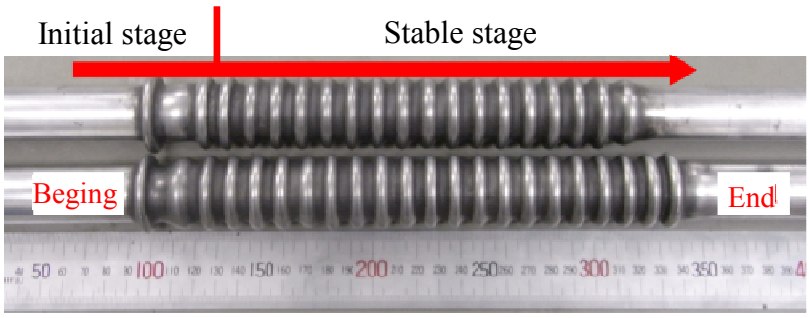

Fig. 2 Aluminum alloy bellows manufactured by semi-dieless forming process with local heating technique (Temperature, 400°C; Compression ratio, C=1.7).

Effect of compression ratio on the convolution shape. The compression ratio has a significant influence on the convolution shape of bellows manufactured with semi-dieless forming process. The lateral section of a convolution of aluminum alloy bellows is shown in Fig. 3. The thickness and shape of convolution of aluminum alloy metal bellows manufactured with different compression ratios were also given in Fig. 3. The tangent lines of the convolution were drawn from the given point which located on the center line of the convolution and with a distance of 500μm from the out surface of convolution. The included angles of the tangent lines of convolution were used to study the bending deformation of tube wall during the manufacturing process of aluminum alloy bellows. The included angles become smaller ($\alpha_1 > \alpha_2 > \alpha_3 > \alpha_4$) with the increase of compression ratio from 1.3 to 1.7, as shown in Fig. 3.

The measured thicknesses of the convolution peak of aluminum bellows obtained with different compression ratios are presented in Fig. 4. The original wall thickness of the aluminum alloy tube is 2mm. After the forming process, the wall thickness in the peak point of the convolution became thicker comparing to the tube original thickness of 2mm. However, the compression ratio did not show significant influence on the thickening of wall thickness during semi-dieless bellows forming process. By analyzing the semi-dieless bellows forming process, it was known that the tube wall of the heating part was thickened by the compression deformation, as shown in Fig. 1(b). For the semi-dieless bellows forming process with different compression ratios, the tube wall thickening process is almost the same. But the duration of the thickening stage is different with that at the same V_1. The duration of the thickening stage became shorter with the compression ratio increasing from 1.3 to 1.7. So, it can be conjectured that for the same tubular material, the compression ratio does not have a significant influence on the amount of thickening when the heating temperature is the same.

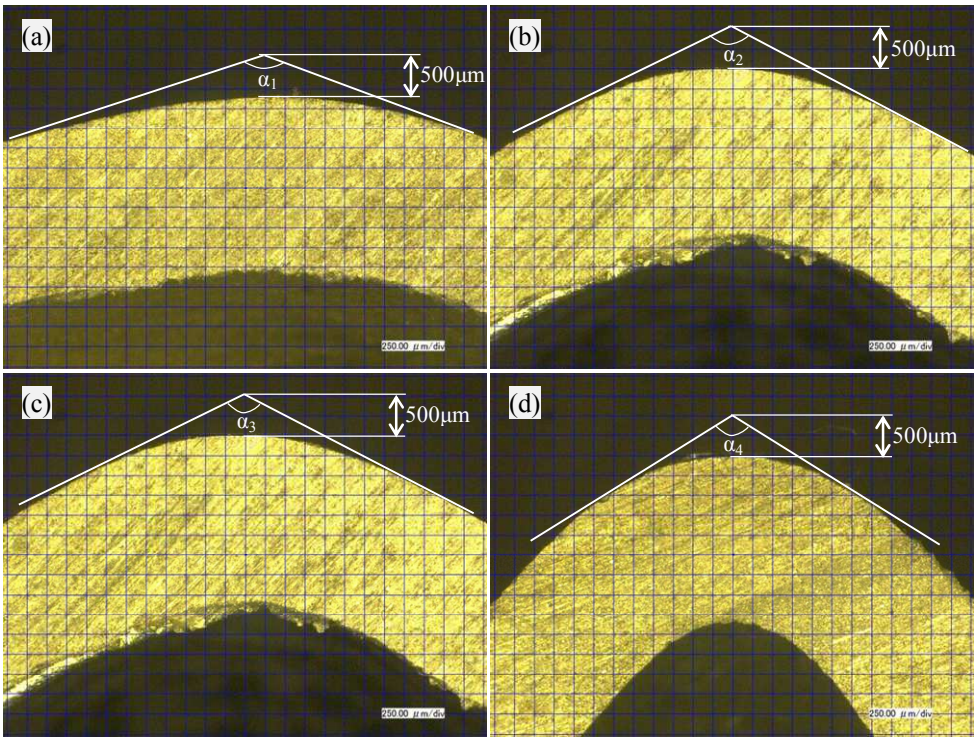

Fig. 3 Convolution shape of Al bellows obtained with different compression ratios. ((a) *C*=1.3; (b) *C*=1.5; (c) *C*=1.6; (d) *C*=1.7)

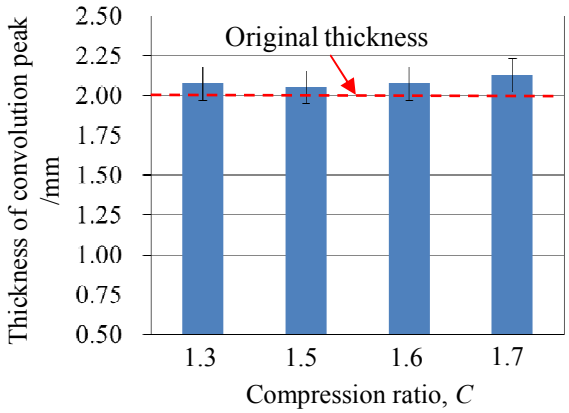

Fig. 4 Effect of compression ratio on thickness of the convolution peak.

Effect of compression ratio on the convolution height and pitch. How to obtain the expected convolution height and pitch of the metal bellows is one crucial technique in the bellows manufacturing process. In the new proposed semi-dieless metal bellows forming process, the convolution height and pitch can be controlled by the compression ratio. The effect of compression ratio on the convolution height and pitch of aluminum alloy bellows are presented in Fig. 5. It can be observed that the convolution height increased with the increase of compression ratio in the range from 1.3 to 1.7. The compression ratio also showed a significant influence on the pitch (distance between the adjacent crests) of the metal bellows manufactured with semi-dieless metal bellows forming process, as shown in Fig. 5. The pitch became smaller with the increase of compression ratio in the range from 1.3 to 1.7. With the increase of compression ratio, the reduction rate of pitch became small. When the compression ratio increases to the limit value, the pitch will also decreases to the smallest.

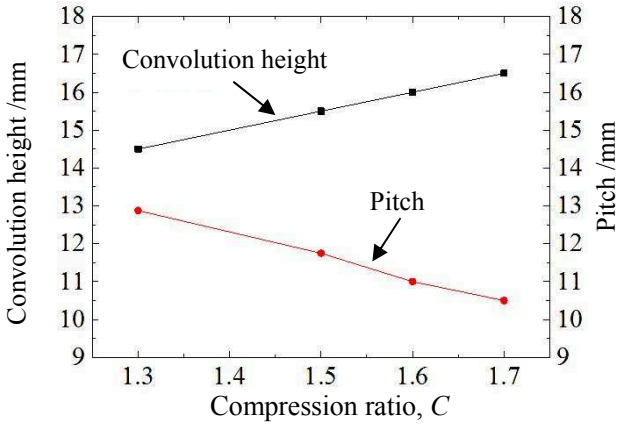

Fig. 5 Effect of compression ratio on the convolution height and pitch.

Summary

In the present paper the deformation behavior of aluminum alloy tube in semi-dieless metal bellows forming process with local heating technique was studied. The effect of the compression ratio on the convolution shape, convolution height and pitch were investigated. The main conclusions were summarized as follows.

1) Even the aluminum alloy tube with high coefficient of thermal conductivity was successfully used to manufacture the bellows with a uniform shape by the semi-dieless forming process with local heating technique.

2) For the semi-dieless bellows forming process with different compression ratios, the tube wall thickening process is almost the same.

3) The convolution height increased and the pitch decreased with the increase of compression ratio in the range from 1.3 to 1.7.

Keywords: X80; pipeline; girth welds; welding procedures; structures and properties

Abstract: The X80 girth welds were produced by solid-wire gas metal arc welding (GMAW) and shield metal arc welding (SMAW) using two welding consumables respectively, which contained different mass fraction of C, Mo and Ni. The tensile properties, notch toughness, hardness, and microstructures of welded joints were evaluated. The results indicate that high strength and good toughness of welded joints can be achieved. But the tensile properties of all weld metal of GMAW and SMAW process were evidently different because of the difference of mass fraction of C, Mo, Ni. The strength reduced slightly in softening zone of HAZ. Using welding consumable which contain higher Mo additions, the microstructure in filler weld and fusion zones were IAF+GB and GB+M respectively. Furthermore, the mechanical properties of X80 pipeline welded by single wire welding and double wire welding respectively have been compared. The double wire welds exhibited lower yield strength but higher toughness compared to the corresponding single wire welds.

Introduction

With the increasing demand for energy source and the declining output from existing reserve, the petroleum and natural gas were developed from more remote and harsh regions such as desert, polar region and blue water. So the gas or oil must be transmitted by large diameter and high strength pipeline to reduce the operation costs. The Canada pipeline industry has demonstrate that pipe wall thickness can be reduced by 14% by using X70 compared to X60 and further 12.5% by using grade X80 compared to X70[[1],[2]]. At the present time, API Spec. 5L X80 has become accepted practice in Canada and Europe. In China, X80 has been used on a large scale in the 2nd West-East Pipeline Project. And the use of X100 and X120 in pipeline systems has been widely investigated to increase economic advantages.

However, the metallurgical properties of high grade linepipe and potential weld metals are such that consumable selection, welding procedure development and production welding controls will require comprehensive testing to ascertain their feasibility in the field. The incremental change in technology between X70 and X80 is significantly more complex than it was between X60 and X70, with markedly different microstructures present in both linepipe and potential weld metals. One of the major challenges in high strength pipeline construction is producing girth welds that both possess enough tensile strength and also exhibit excellent toughness. In order to control grain size and microstructure morphology lower heat input and suitable preheated temperature should be adopted [3]. In addition, as strength increases, so does the risk of weld metal hydrogen-assisted cracking (HAC). This is particularly important for pipeline construction since pipeline girth welds are inspected shortly after welding and, as results; there can be no risk of delayed cracking. In the harsh conditions, the high productivity with minimum intervention by the welder should be also taken into account for the welding of large diameter gas transmission pipelines to shorten the construction time limit for a project [4].

To fully realize the economic benefits associated with application of high strength pipeline steels, welding processes and procedures must be developed and assessed to ensure the requirement

for overmatch strength, combined with excellent toughness, are achievable in field girth welds. The work presented in this paper was focused on the mechanical properties and microstructure of girth welds of grade X80 pipeline.

Experimental Material and Methods

Experimental Material

The welding trials were performed using X80 Longitudinal seams submerged-arc welded pipe (SAWL pipe). The pipe sizes were 1016.0mm diameter, 22.0mm wall thickness. The bulk composition of the base metal is 0.069C-1.91Mn-0.18Cr-0.27Ni -0.26Cu. The quantities of other microalloying element, such as Mo (0.022wt %), Nb (0.036wt %), V (0.049wt %), and Ti (0.015wt %) were small. The microstructure of the pipe body was bainitic ferrite (B), polygonal ferrite (PF) and pearlite (P). The tensile properties in the longitudinal and transverse directions of the X80 pipe body were measured by extracting standard ASTM E8 round tensile specimens (0.500-in diameter). Yield strengths of 598 and 676 MPa were measured in L-T and T-L tensile specimens. Similarly, tensile strengths were respectively 670 and 716 MPa giving Y/T ratios of 0.89 and 0.94. The tensile strength of the welded joints of pipe was 730 MPa, and the fracture location at base metal. The full-size (10-×10-×55-mm) standard CVN specimens were machined and tested at 20℃. The average impact energy of pipe body and welds and HAZ were respectively 271J, 162J, and 215J.

Welding Procedures

A series of X80 pipeline girth welds were prepared by semi-automatic gas metal arc welding (GMAW), manual shield-metal arc weld (SMAW) and automatic gas metal arc welding (GMAW) using single wire and double wire. The girth seams were welded by using vertical down on full-scale pipe sections in the horizontal (5G) position. For GMAW, two solid C-Mn-Si electrode wires with Mo-Cu-Ti, and Ni- Mo-Ti alloy additions were selected for this evaluation. The electrode wires were classified as ER80S-G and ER90S-G respectively. GMAW was carried out using the short circuit transfer mode with shielding gases; 85%Ar-15%CO2 for the root and cap passes, and 100%CO2 for all fill passes. For SMAW, the filler welding and cap welding utilized C-Mn-Si electrodes alloyed by Ni-Mo-Ti (classified E11016-G) and Ni-Ti (E10018-G), bur the root welding used the same electrode E8018-G. The welding consumables are given in Table 1. The pipes were initially preheated to 150°C. And the Precise control of preheat interpass temperatures were controlled precisely.

TABLE 1. WELD IDENTIFICATION AND CONSUMABLE FOR X80 PIPELINE GIRTH WELDS

Weld	Welding consumable		
	Root pass	Fill pass	Cap pass
GMAW-B	Bohler NiMo 1-1G, 0.9 diameter (ER 90S-G, Ni-Mo-Ti)	Bohler NiMo 1-1G, 0.9 diameter (ER 90S-G, Ni-Mo-Ti)	Bohler NiMo 1-1G, 0.9 diameter (ER 90S-G, Ni-Mo-Ti)
GMAW-N	YM-60A, 1.2 diameter (ER 80S-G, Mo-Ti)	YM-60A, 1.2 diameter (ER 80S-G, Mo-Ti)	YM-60A, 1.2 diameter (ER 80S-G, Mo-Ti)

Mechanical Testing and Metallographic Analysis

A series of tensile tests were conducted on X80 girth welds using round and strip tensile specimens. Round and strip tensile specimens of welded joints were cut parallel to the pipe axis welds. The strip tensile specimens of welded joints were cut at the major clock positions, i.e., near 1:00-2:00, 4:00-5:00, 7:00-8:00, 10:00-11:00. The round specimens were machined from the mid-thickness of welded joints near 4:00-5:00 and 9:00-10:00. To further understand the all-weld-metal properties of different welding procedures, the tensile tests using round specimens that were cut from 5:00-6:00 and 9:00-10:00. All tensile testing was carried out at room temperature using a

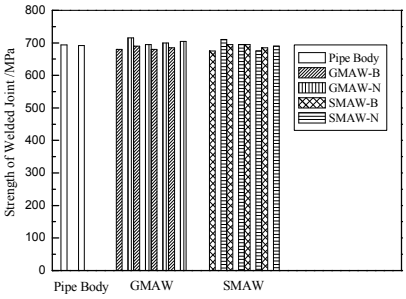
universal testing machine. The round specimens utilized a 25.4 mm gauge length and appropriate extensometer to allow full stress-strain curves to be obtained. Subsequent plotting and analysis of the data allowed the engineering yield strengths (0.5 % extension), and ultimate tensile strength to be determined, along with the percent elongation.

To evaluate the weld metal and heat affected zone (HAZ) notch toughness properties a series of full-size (10×10×55 mm) Charpy specimens were cut transverse to the girth weld from major clock position 12:00 and 3:00 and notched through-thickness at the weld centerline and fusion line. Triplicate tests were conducted at 20℃. To further assist with characterization of the weld joints, a series of Vickers hardness surveys were conducted along the through thickness centerline, as well as across the entire weldment to provide a relative indication of the strength variation between the pipe base material, heat-affected zone and weld metal regions. The cross-weld surveys were made at positions near the subsurface OD, mid-thickness, and sub-surface ID (root region) locations.

The full-thickness weld sections were cut transverse to the weld and prepared using standard metallographic techniques. The samples were assessed by optical microscopy to characterize the microstructure of weld metal and HAZ.

Results and Discussion

Weld Metal Chemical Composition



The chemical compositions of weld metal are given in Table 2. There are obvious differences in chemistry between the welds produced by GMAW using ER 90S-G and ER 80S-G. The most notable being the higher Mo and Cu but lower C, Cr, Ni for the GMAW-N weld. In the same way, the carbon contents of SMAW-N welds is lower but the Mn, Mo, Ni are higher than the contents of GMAW-B welds.

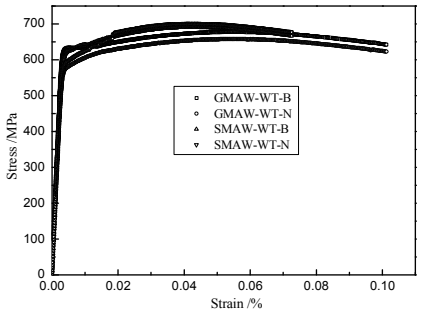


TABLE 2. CHEMICAL COMPOSITIONS OF X80 PIPELINE GIRTH WELDS (MASS FRACTION / %)

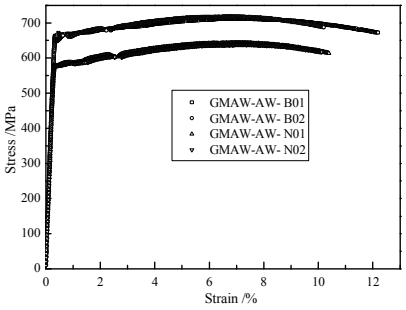
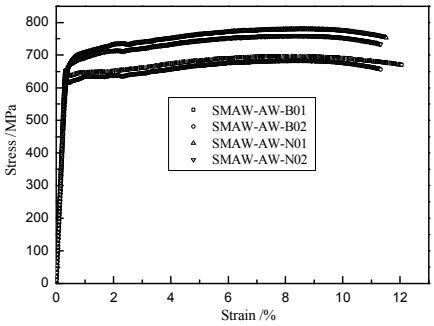
Element	C	Si	Mn	P	S	Cr	Mo	Ni	Nb	V	Ti	Cu
GMAW-B	0.066	0.55	1.52	0.006	0.010	0.088	0.26	0.82	0.010	0.009	0.028	0.14
GMAW-N	0.040	0.40	1.62	0.011	0.0061	0.015	0.38	0.012	0.007	0.006	0.023	0.25
SMAW-B	0.070	0.45	1.39	0.008	0.008	0.038	0.031	2.08	0.011	0.024	0.016	0.06
SMAW-N	0.034	0.42	1.60	0.014	0.0040	0.029	0.50	4.39	0.012	0.015	0.011	0.03

Mechanical Properties of Welded Joints and all Weld Metal

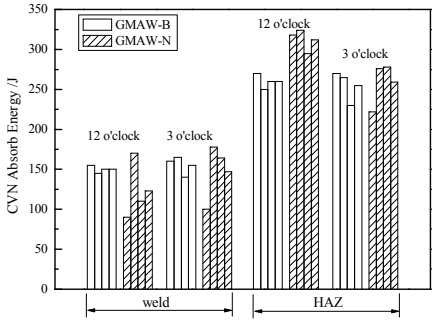


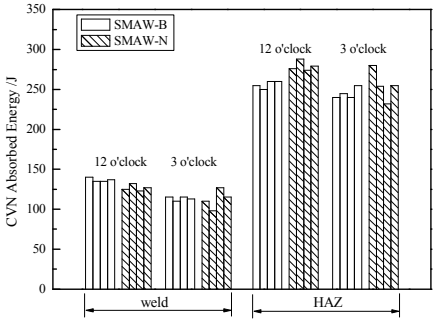
The tensile properties measured in welded joints specimens are shown in Figure 1. The data from figure 1(a) shows that the tensile strength of welded joints produced by GMAW and SMAW can be achieved the strength level of pipe body although the carbon contents are lower for the GMAW-N and SMAW-N welds. So the Mo contents have significant effect on the strength of welded joints, Fig. 2. However, the figure 1 shows distinctly that the strengths of joints welded by GMAW using ER 90S-G are a bit higher than that of joints welded using ER 80S-G. An important observation is the similar forms of stress-strain curves for the round specimens of welded joints, which exhibited continuous or roundhouse yielding behavior, Fig. 1 (b). These data demonstrate that the tensile results from round tensile specimens equally detect the yielding behavior of pipe material because the strengths of joints are higher than that of pipe body.



(a) Tensile strength of pipe body and welded joints (b) Stress-strain curve obtained from round specimens

Figure 1. Tensile properties of X80 pipeline girth welds





(a) GMAW (b) SMAW

Figure 2. Stress-strain curve obtained from round specimens of all-weld metal for (a) GMAW and (b) SMAW

The Charpy impact test results of welded joints for GMAW and SMAW are summarized in Figure 3. The average CVN impact energies measured in weld metal and HAZ welding were above 110J and 240J at 20℃ respectively. But the CVN absorbed energy values of welded joints for GMAW-N and SMAW-N are more dispersive than that of welded joints for GMAW-B and SMAW-B. Whether GMAW-B or SMAW-B, the Charpy impact energies are higher in welds but lower in HAZ. The very high levels of single impact value measured in GMAW-N weld are very encouraging with respect to finding a robust welding process/welding procedure that will allow a balance of high strength and good temperature toughness to be consistently achieved.

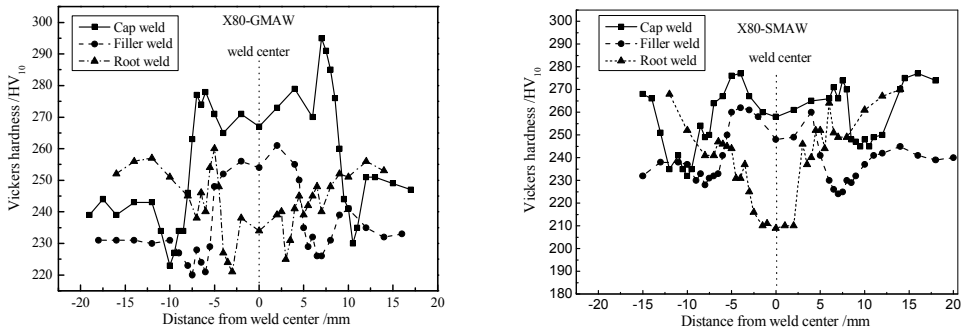


Figure 4 shows the distribution of Vickers hardness of welded joints for GMAW-B and SMAW-B. It was found that hardness would range from 210 HV10 to 300 HV10. The data demonstrate that the hardnesses of cap pass are higher than the values at fill pass and root pass. Furthermore, the maximum hardness is at the fusion line location with minimum value in softening zone of HAZ. So the strength in softening zone for X80 pipeline girth welds will reduce slightly than the base metal.

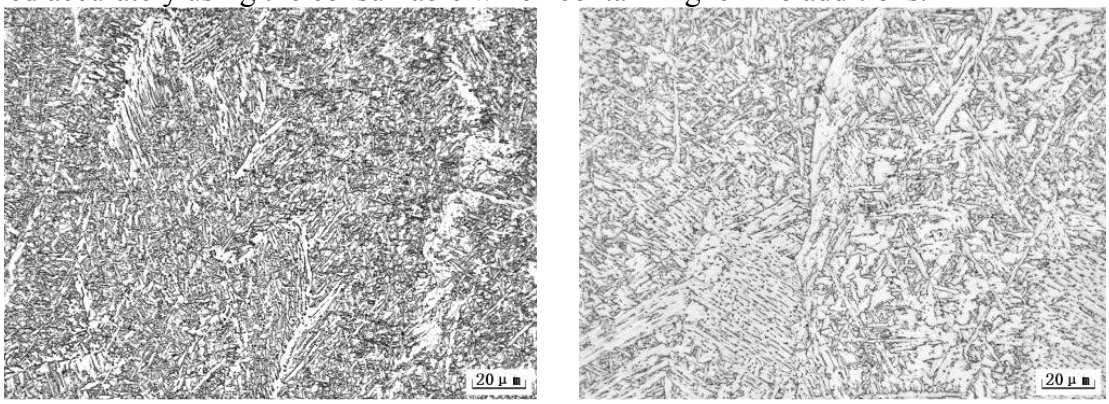
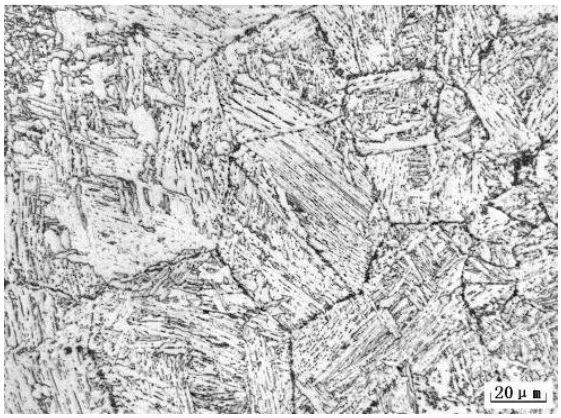
Figure 4. Hardness measured in welded joints

Comparison of Mechanical Properties of Welded Joints for Double and Single Wire Welding



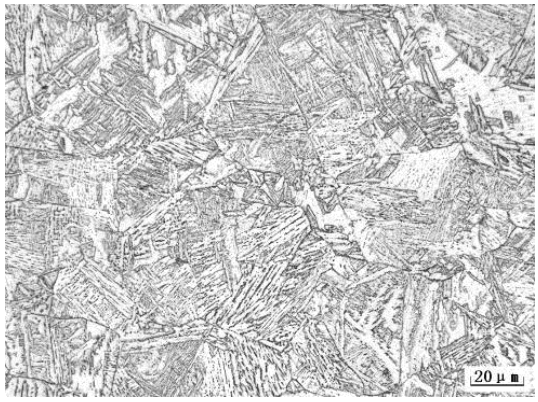
The tensile results, Charpy and CTOD results from tests for double and single wire welding are listed in Tables 3. There were slightly lower yield strengths and ultimate strength observed for the double wire welds. The data also show a trend of increasing impact toughness and generally higher fracture resistance for the welds of double wire welding as compared to the corresponding single wire welding.

Table 3. Mechanical Properties of welded joints of double and single wire welding for X80 pipeline



Weld consumable	Welding process	Tensile properties /MPa		CVN absorbed energy /J		CTOD（－10℃）/mm		
		$R_{t0.5}$	R_m	-40℃	-10℃	Min.	Max.	Avg.
Bohler NiMo1-1G (C-Mn-Si-Ni-Mo-Ti)	Single wire	704	755	72	98	0.22	0.29	0.26
	Double wire	662	729	95	122	0.23	0.39	0.33

Microstructure of Welded Joints



The representative micrographs of X80 pipeline girth weld are shown in Figure 5 and Figure 6. The optical micrographs reveal the predominantly columnar as deposited weld metal structure. As can be seen a relatively high proportion of intra-granular nucleated acicular ferrite (IAF) with bainite (B), polygonal ferrite (PF) and pearlite (P) was formed in GMAW-B and SMAW-B welds. But the microstructures of GMAW-G and SMAW-N welds are IAF and grain boundary ferrite (GBF). And the IAF structures formed in the GMAW-N and SMAW-N welds were generally coarser compared to the GMAW-B and SMAW-N welds. Furthermore, martensite (M) is observed in fusion zone of GMAW-N and SMAW-N. So, it is worth noting that the heat input should be controlled accurately using the consumable which contain higher Mo additions.

Conclusions

This experimental investigation provides data on the mechanical and structure properties of X80 pipeline girth welds produced by GMAW and SMAW. The results indicated that high strength and good toughness of welded joints can be achieved. But some precision is required in the control of welding parameters to avoid the forming of martensite (M) using the welding consumable which contain higher Mo additions. For X80 pipeline, the hardnesses in softening zone are lower than base material, so the strength reduces slightly. The double wire welds exhibited lower yield strength but higher toughness compared to the corresponding single wire welds. The application of double wire welding in high grade pipeline girth welding not only can improve the mechanical performance of the welded joints, but also can raise the welding efficiency.

Keywords: Spray formed, 7XXX aluminum alloys, Porous defects

Abstract: In this work, Al-10.8Zn-2.8Mg-1.9Cu alloy was manufactured by the spray forming technique. The microstructure of the spray-formed alloy was investigated by optical microscopy and field emission scanning electron microscopy. The results indicated that the porosity in the spray-deposited alloy was mainly composed of interstices, interconnected pores and gas pores. The distribution and types of porous defects were different, responding to position of the preform.

Introduction

Spray forming introduced by Singer at the University College of Swansea during 1970s, has been applied to manufacture high strength 7XXX Al alloys [1, 2]. Compared with conventional metallurgy, spray forming presents several advantages, however, porous defects cannot be avoided in as-deposited materials with the accomplishment of inert gas atomizing liquid alloy into droplets and depositing solidification on the collected substrate [3]. The presence of porosity especially gas pores and interconnected pores will greatly reduce the high strength and high resistance to cyclic deformation [4-6]. The inherent porosity in deposited alloys may reduce the mechanical properties at high temperature.

All the time, little considerable attention is paid to porous defects [7], owing to the difficulty of characterization methods and numerous influence factors. The smooth industry application of spray forming is restricted by the fundamental mechanisms controlling porosity formation and evolution. The previous reports have no systematic summary of porous defects in spray-deposited 7XXX alloys, which restricted the densification and industry application of spray-deposited 7XXX alloys.

In this paper, Al-10.8Zn-2.8Mg-1.9Cu alloy was produced by the spray formed technique. The present work was aimed at classifying porosity at different position in as-deposited 7XXX aluminum alloys and studying formation of porous defects.

Experimental

The composition of the studied alloy was Al-10.8Zn-2.8Mg-1.9Cu (mass fraction, %). The spray-deposition experiments were conducted with a SF-200 type environmental chamber.

The microstructures of the alloy were characterized with OM (Zeiss Axiovert 200MAT), and FESEM (JEOL JSM 7001F), operated at 15 kV. The investigated alloys were abraded and polished

without etching. The amount of nitrogen in the alloy preform was conducted using LECO TC436 Nitrogen/Oxygen Determinator through inert gas pulse infrared thermal conductivity method. The photo and sample positions are shown in Fig. 1. The investigated preform bars have dimensions of 10 mm × 10 mm × 10 mm.

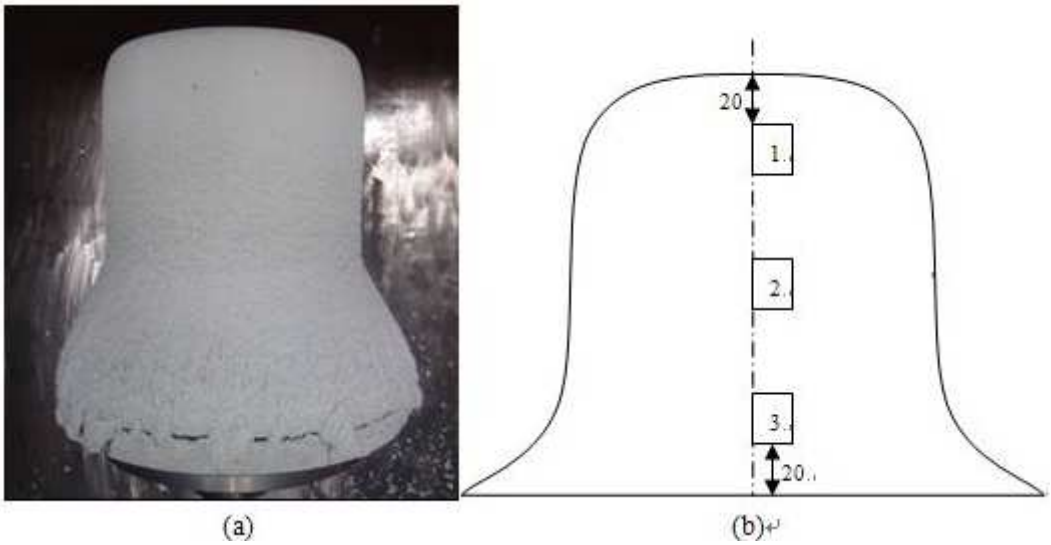

Fig. 1 Position of samples in spray-formed alloy (a) Spray formed deposit; (b) sampling location

Results and discussion

The nitrogen content and density of samples at different positions of spray formed 7XXX alloy are shown in Table. 1. It indicates that nitrogen content in the deposited alloy center is lower than that of the top and the bottom. Owing to high cooling rate, the density in the edge of the preform is higher. And the nitrogen in the preform has nothing to do with the density distribution.

TABLE 1 NITROGEN CONTENT AND DENSITY OF SAMPLES AT DIFFERENT POSITIONS

samples	1	2	3
N wt.%	70ppm	58ppm	70ppm
density %	90.4	90.9	91.3

Fig. 2 shows the microstructures on the preform topside, which contains several kinds of porous defects. Interstices with size less than 30μm, which exhibit irregular morphology, are easier to be found (Fig. 2a). The spherical inward gas pores with size of about 10 μm can be seen in Fig. 2c. Inside spherical pores, the pore wall is smooth, grain boundaries are coarser than outside, the number of secondary phases in the grains is increased and the size is larger. When there is an excessive amount of liquid present in the atomized droplets during deposition, liquid alloy droplets may entrain inert N_2 to bring into gas pores, which have smooth walls because of gas pressure. Single interstices distribute along grain boundaries with size of several microns to tens of microns (Fig. 2d). The morphology of interstices is anomalous and pore wall is

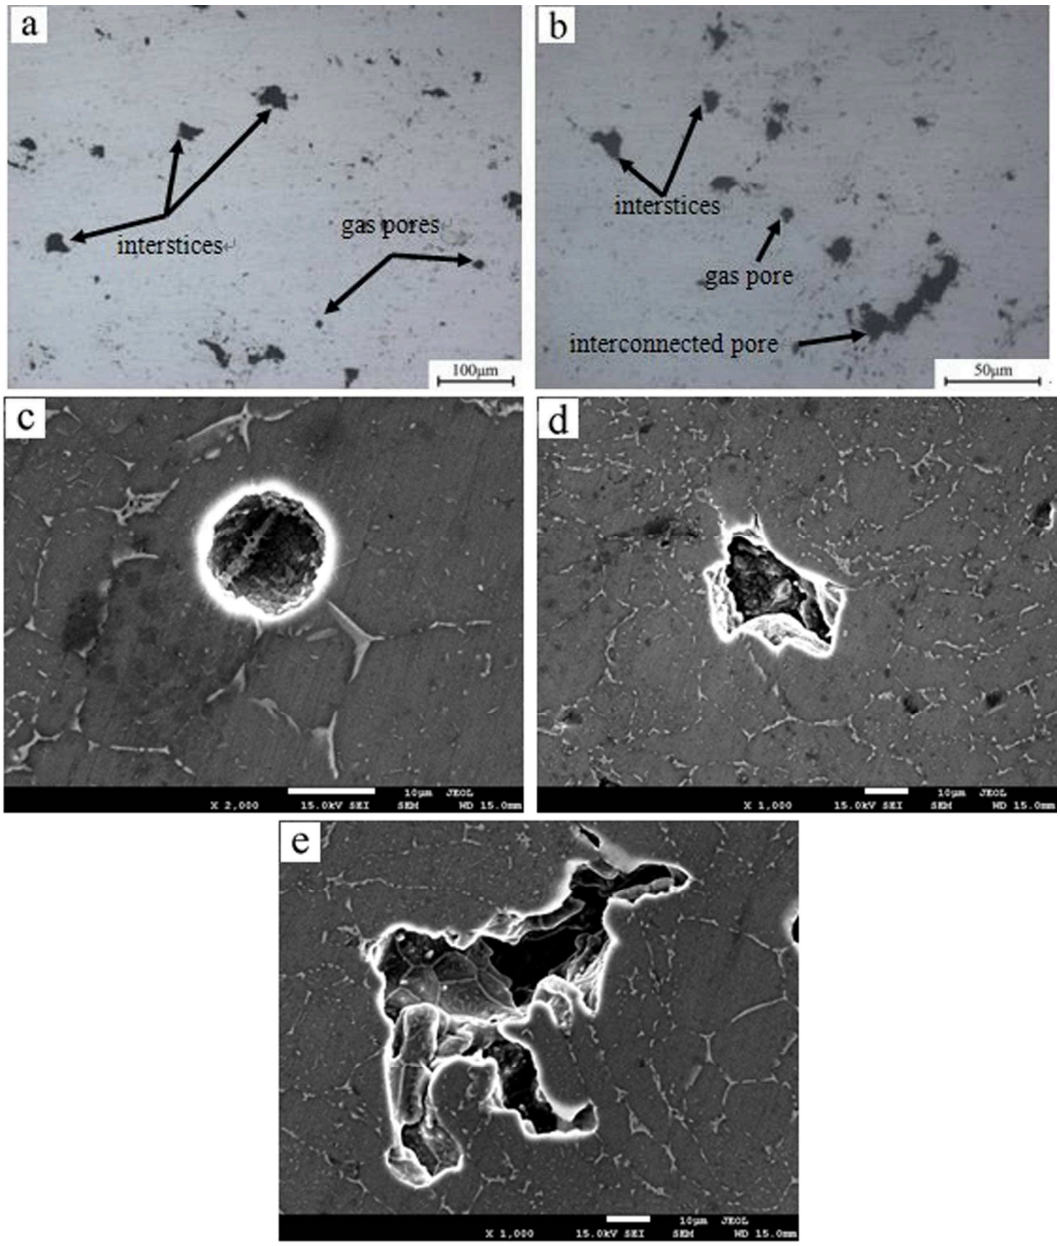

Fig.2 Microstructures of spray-deposited alloy (1# position)

very coarse. This type of porosity is generated as a result of the incomplete filling of the voids between solid or partially solidified droplets. One important difference between gas pores and interstices lies in the morphology, which is dented and smooth because of gas pressure for gas pores. Interconnected pores can be obviously observed from Fig. 2e, which have bigger size and interconnected channels.

The microstructures in the center of the alloy have been shown in Fig. 3. The porous defects in this area consist of single gas pores, interstices and a few interconnected pores with little size. Single gas pores have sizes about 10μm (Fig. 3c), the size of interstices is mostly less than 20μm (Fig. 3a, b), and interconnected pores are also restricted within 40μm (Fig. 3b). Both the size and amount of pores in the center of as-deposited alloy are smaller than that in the topside. Interconnected pores arise along grain boundaries with long and thin morphology (Fig. 3d).

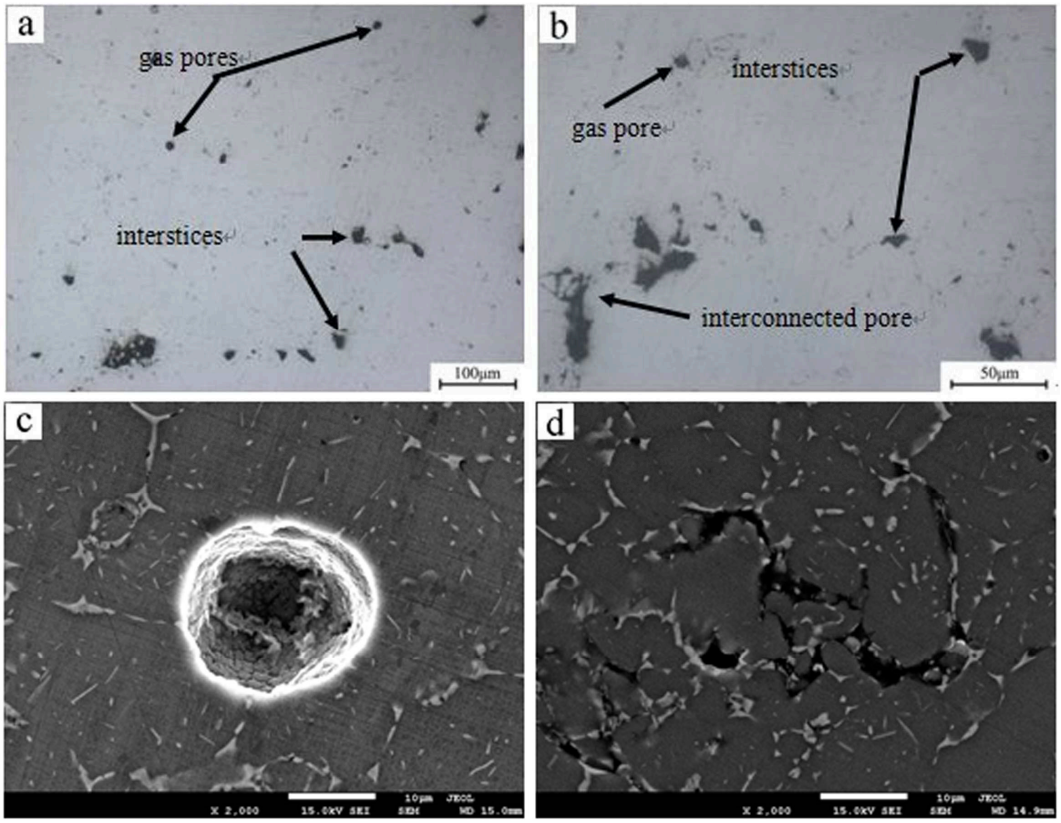

Fig. 3 Microstructures of spray-deposited alloy (2# position)

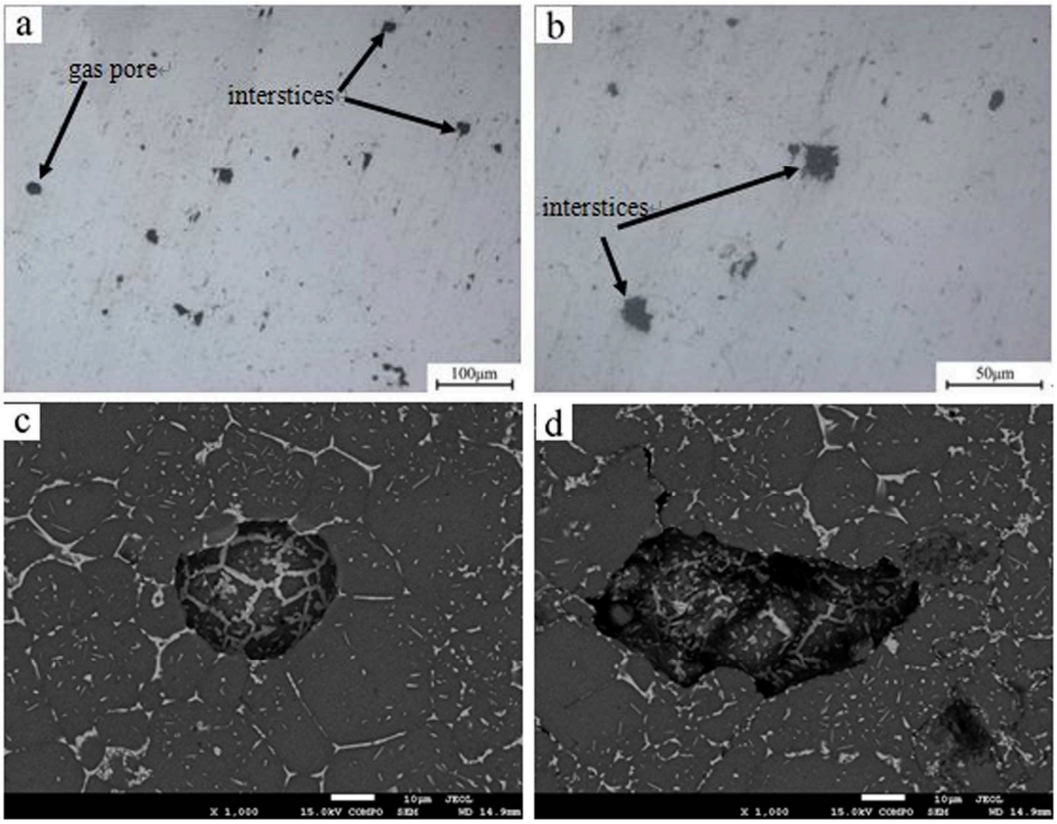

Fig.4 Microstructures of spray-deposited alloy (3# position)

Fig. 4 shows the microstructures of 3# position in spray-deposited alloy, with the defects of single interstices and a few gas pores. There are short of large interconnected pores here. 3# position locates closer to the substrate where the coming droplets have already solidified, so the interstices will come into being as the body after droplets impinging with the surface. The

interstices with size of about 30μm are partly filled with particles (Fig. 4d). The gas pores in this area have spherical morphology with size of about 30μm (Fig. 4c). And grain boundaries inside the gas pores are broader than outside.

In summary, there are several types of porous defects in spray-deposited alloy, which are different with the position of the preform. The final microstructure is strongly related to the cooling of droplets and deposited materials [3]. Plenty of droplets in atomizing cone experience complicated procedures during spray forming, so the porosities in the preform have several morphologies and distribute unevenly.

Conclusion

The porous defects of spray-deposited Al-10.8Zn-2.8Mg-1.9Cu alloy are composed of single interstices, gas pores and interconnected pores. The porosity expresses mainly single and interconnected pores in the upper of as-deposited billet, single interstices and gas pores in the center and single interstices on the base of deposition billet. There are more interconnected pores on the side of as-deposited billet. The grains and intragranular precipitates around gas pores are bigger than that of interstices. The walls inside gas pores are smooth and concave and the morphology of gas pores remains near spherical.

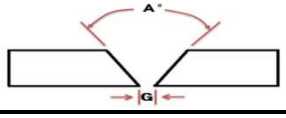
Keywords: GMA Welding Process, Mahalanobis Distance, Neural Network, Error Backpropagation Algorithm

Abstract. Gas Metal Arc (GMA) welding is considered as a multi-parameter process that it's hard to find optimal parameters for good welding. To overcome the problem, an artificial neural network based on the backpropagation algorithm was built to realize the relationships between process parameters and welding quality as output parameter. In this study, Mahalanobis Distance (MD) was employed to evaluate the availability of a given welding parameters which was proved to performance well in multivariate statistics. Input parameters such as welding current and arc voltage were chosen due to their significant influence on the welding quality. To improve the precision of given parameters' evaluation, neural networks with different configurations were verified. The analyses on the measured and predicted MD by the proposed neural network were conducted. The proposed neural network based on the error backpropogation algorithm was proved to have high reliability to evaluate process parameters, which further makes it available in on-line monitoring system.

Introduction

For the automated welding system, optimal welding parameters for the GMA welding process should be well established and categorized. Thus, it is necessary to develop an intelligent algorithm to obtain suitable process parameters in the automatic GMA welding process. However, the waveform of welding current and arc voltage obtained from the on-line monitoring system differ slightly from the fault weld and good weld [1]. It is very difficult to find the good and fault waveform. Therefore MD is applied to character the welding quality. If the distance between the test point and the centre of mass is less than one standard deviation, then we might conclude that it is highly probable that the test point belongs to the set.

With the development of computational technology, the neural networks appear to constitute a workable model for predicting the bead geometry under given set of welding conditions according to the work done by Nagesh and Datta [2]. Srikanthan and Chandel [3] proposed the steps adopted to construct the neural network model for GMA welding process and evaluated the proposed neural network model. Kim et al. [4] used the backpropagation neural network to predict bead geometry for GMA welding process and proved that the proposed neural network model can predict bead geometry with reasonable accuracy. However, the accuracy of the prediction depends on the algorithm employed in the neural network. Backpropagation learning algorithm is the most widely applied neural network model [5, 6]. To achieve a high level of welding performance and quality, a suitable algorithm is required to fully understand the influence of welding parameters on MD in the GMA welding process.



This study attempts to develop an optimal neural network to establish relationships between the input and output parameters for applying the robotic GMA welding process. The neural network with the error backpropagation algorithm is firstly established. Secondly, the averaged RMS error is

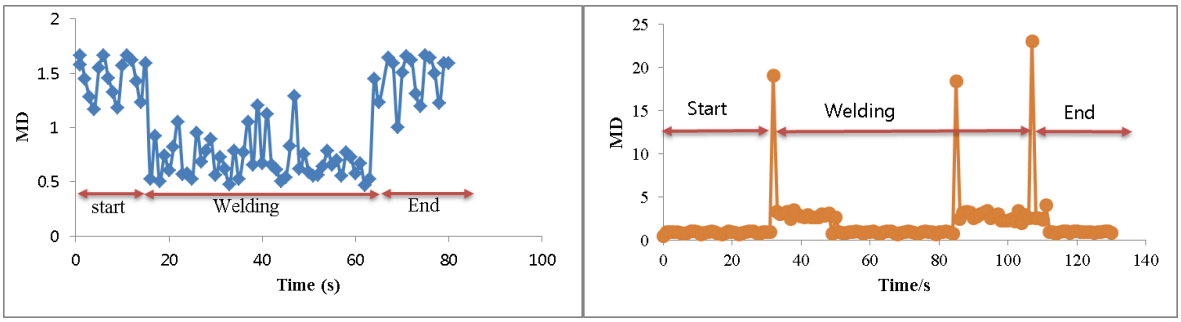
calculated. Finally, comparison of the qualitative and quantitative analysis of GMA welding faults based on MD by the error backpropagation algorithm with different numbers of neurons is presented. Results indicate that the error backpropagation algorithm is the preferred algorithm for building neural network in the prediction of MD in GMA welding process.

Description of GMA Welding of Steel

To perform GMA robotic welding on SM490A steel which is mainly used in marine pressure vessel requires specification on the manual welding condition. Table 1 represents details of GMA welding process based on standard Welding Specification Procedure (WPS) and manual welding conditions based on preliminary experiments to drive a stable bead area.

Table 1 The details of robotic GMA welding process

	Details		Details
Joint Type		Welding Wire	AWS ER70S-3
		Shielding Gas	CO_2 99%
Groove Angle	60°	Root Gap	1[mm]
Base Metal Grade	SM490A	Welding Length	400[mm]
Thickness	12[mm]	Evaluation Item	Welding Condition (Amp/Volt/Speed/Weaving)



The MD is a descriptive statistic that provides a relative measure of a data point's distance (residual) from a common point. It is a unities introduced by Mahalanobis in 1936 [7]. Similarly, the welding quality whether it fault or good could be determined by the observated MD space of the multivariate outliers for the input parameters such as welding current and arc voltage in the GMA welding process. If the magnitude of MD derived from a welding current C_i and arc voltage V_i is smaller than a certain value, the parameter of (C_i, V_i) can be considered as a suitable value and good weld will be produced. The smaller the MD is, the better the weld quality will be [8].

To provide reliable data for recognition of welding current and arc voltage on welding quality, the MD equation is transformed by means of robust procedure complied in MATLAB software. The transformed equation is defined below:

$$M_d = \frac{V_i'^2 - 2rV_i' + C_i'^2}{1 - r^2} \tag{1}$$

Where V' and C' indicate the normalized value of arc voltage and welding current, and r is the correlation coefficient after normalization.

As shown in Fig. 1, the welding quality can be easily identified by MD. According to MD concept, a longer data space existence between each other indicates the fault weld. Therefore, Fig. 1(a) is found to be good weld, whereas Fig. 1(b) is found to a fault weld. The start and end welding current and arc voltage are also recorded on the on-line monitoring system, and presented on transformed current verse transformed voltage. The result shows that current and voltage are very low and unstable during start and end welding process but as moves along process, it gets stable. In addition, Fig. 1(b) shows unstable normalized MD results through welding process. The MD values are big during the welding process results to fault weld quality, which is also the results of artificial increase of arc length.

(a) Good quality welding (b) Fault quality welding

Fig. 1 MD distributions with respect to time variations

Modeling of GMA welding process using neural network

The process parameters of the robotic GMA welding process are inter-dependent and constantly in conflict in a complex way. Therefore a structure of feed-forward neural network is adapted to this work. A one-layer feed-forward network is constructed with two input neurons in the input layer and a neuron in the output layer to map the output parameters of MD to two input parameters of welding current and arc voltage. And the schematic representation of the multi-layer neural network architecture employed in this research is shown in Fig. 2.

Modeling of the GMA welding process with neural networks is composed of two phases: training and testing of the neural networks with experimental welding data. The convergence criterion for the developed networks is determined by the average RMS error between the desired output value y_i and predicted output value y_i' for the i th prediction, i.e.:

$$E_{RMS} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - y_i')^2} \tag{2}$$

Where i is the number of training data or testing data. In this study, a specific training algorithm has been employed to train the neural network, and the development architecture of the network is carried out on a Pentium PC using MATLAB.

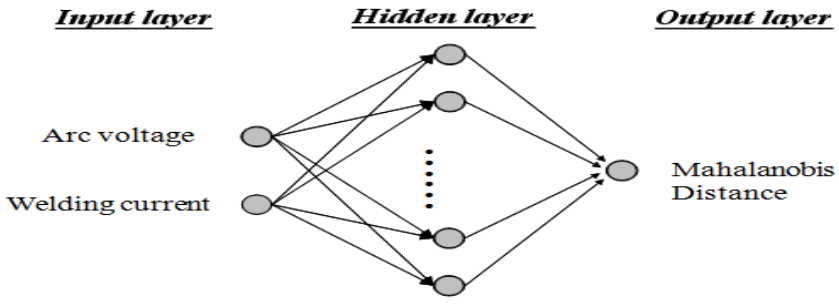


Fig. 2 Optimal neural network architecture for MD

Results and Discussion

To get an effective neural network, a large amount of training examples as much as 12500 are employed. And the trained neutral network is tested by 100 collections of arc voltage and welding current. By simulation, it was found that one hidden layer can provide better convergence in the modeling of the robotic GMA welding process. Network configurations with different numbers of neurons in the hidden layer are studied. The performance of the neural networks could be shown in Table 2. It is found that increase of the number of neurons in the hidden layer does not ensure the

decrease of the average RMS error. For the testing phase, the average RMS error of the testing set is almost the same as that of the training set, which means that the network has good generalization ability for the modeling of the GMA welding process. Furthermore, during the training process, the average RMS error can be reduced to about 0.4059 when the number of neurons in the hidden layer is increased to 16. In other words, this network configuration of 2-16-1 seems to be best for the prediction of the MD with the lowest RMS error. Accordingly, the error backpropagation algorithm provides a good learning ability for the robotic GMA welding process as the training MD presents high consistency with testing ones.

Table 2 The results of various network configurations with the error backpropagation algorithm

Configuration	Training RMS error	Testing RMS error	CPU time for training [min]
2-2-1	0.7500	0.6426	2.23
2-4-1	0.8332	0.6823	2.30
2-6-1	0.5516	0.5150	2.33
2-8-1	0.5213	0.4765	2.35
2-10-1	0.5143	0.4900	2.35
2-12-1	0.5200	0.4920	2.40
2-14-1	0.5019	0.4658	2.40
2-16-1	0.4059	0.3745	2.37
2-18-1	0.5202	0.4925	1.95

Fig. 3 indicates the absolute error between the measured and predicted MD. The lower the values of error are, the better the correlations of the measured MD and predicted MD of separating percentage will be. It can be found that the error of the MD is within 1.2 and the data are mainly distributed within the absolute value of error of 0.4, which indicates that the accuracy of the predicted MD by this method is acceptable.

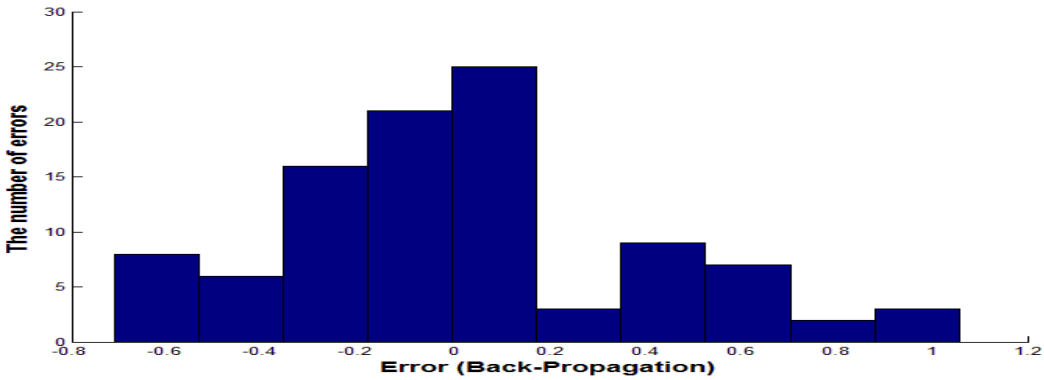

Fig. 3 The error of the predicted MD with error backpropagation algorithm

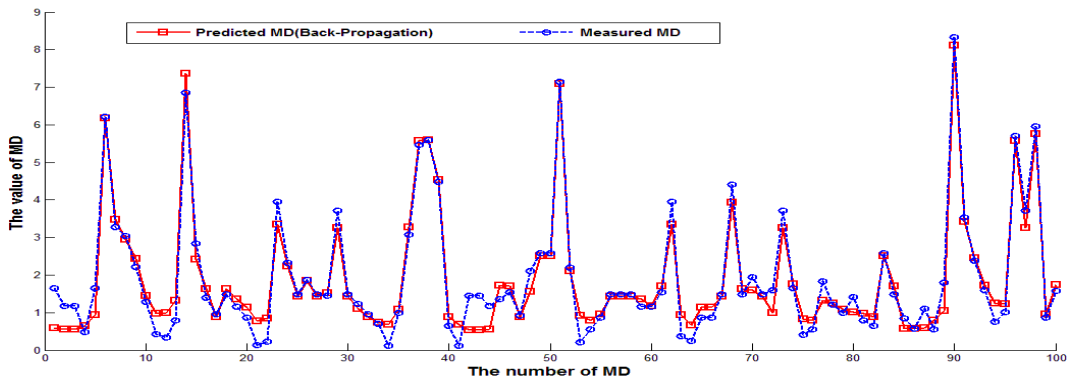

Fig. 4 Performance of the error backpropagation algorithm

The results of the study in the performance with the error backpropagation algorithm are plotted in Fig. 4. In the figure, the solid line with red square represents the predicted MD using the error backpropagation algorithm and the dash line with blue circle represents the measured MD obtained from the developed equation. It is easily observed that the calculated values obtained using the error backpropagation algorithm shows a good accuracy. The worst accuracy point locates at the MD number of 1 and the deviation is the largest with a value of 1.05, while the best one locates at the MD number of 38 with a very small deviation. Therefore, it might be concluded that the amount of the errors generated from the error backpropagation algorithm is still reasonably small to be accepted in most cases of practical applications.

Summary

This study investigates the application of statistical method for quantifying the welding quality in robotic GMA welding. Neural network with the error backpropagation algorithm is established and the one-hidden-layer neural network with configuration of 2-16-1 is found to be the best fit for this application. Not only high consistency between the measured and predicted MD, but also the low value of the error of predicted MD away from the zero point in configuration of 2-16-1 indicate that this developed neural network performs quite well in prediction of MD in GMA welding process. Therefore, the developed models shows a reasonable reliability to predict the on-line process parameters to obtain the desired MD as welding quality, to establish guidelines and criteria for the most effective joint design and further to help the development of automatic control system of arc welding robot.

Keywords: Silicon nanoparticles, nontraditional machining, spark erosion

Abstract: This article demonstrates potential approaches to the production of Silicon Nanoparticles (SiNPs) using spark erosion in forms of Wire-EDM (WEDM), Die-sink and Micro -EDM. Utilizing the data from research work on such commercialized spark erosion approaches, a novel method of nanoparticle production by spark erosion under high pressure flushing has been introduced in this paper. This system is a crossbreed of Die-sink and Small Hole-EDM that comprises deionized water sprayed @ 0.8 MPa through a rotating copper tube as an electrode, boring on boron doped silicon ingot workpiece, under submerged conditions. SiNPs constituting an average diameter of 50nm were generated with approximate productivity of 1.5g/hr from the high pressure flushing system. The productivity of the nanoparticles for every system was calculated after post-process purification. The results demonstrate that SiNPs production from spark erosion, in terms of size and productivity, is least affected by electrical parameters, rather is much dependant on other aspects, such as pressure of dielectric flushing as well as dielectric type. The results also show that high pressure flushing spark erosion process holds excellent potential as an industrialized SiNPs preparation method in terms of size and productivity.

Introduction

SiNPs can be produced via physical and chemical approaches. From the chemical approaches, Stöber Process is perhaps the most popular method for metal coating with silica [1] [2], producing SiO_2 spheres with diameters ranging from 200 to 800 nm [3]. There is also Chemical Vapor Deposition (CVD)[4], which can produce very fine single crystal spherical particles under decomposition of silane/disilane gas [5], with varying distribution from 40nm to 100nm [6]. Additionally inductively coupled plasma (ICP) has reported to produce well-defined highly crystalline SiNPs [7], with an average diameter of 13nm.

Along with chemical approaches, non-traditional physical approaches for silicon nanoparticle production potentially higher production capability over chemical approach such as Sol gel [8]. Laser ablation (LA) is a nontraditional nano production technique [9], that produces pure SiNPs in gaseous medium having a distribution of 60 to120nm & 25 to 100nm in liquid [10].

Spark erosion is another nontraditional physical approach could very well be one of the most resourceful non-traditional techniques for generation of NPs. Similar to laser ablation, spark erosion has similar mechanism of material removal, i.e. to completely vaporize workpiece material as method of erosion. However spark erosion has the potential to produce NPs at large quantities, an area which laser ablation lacks due to its low productivity, especially in liquid mediums [11]. Commercial spark erosion by electro discharge machines (EDM) in forms of Wire-EDM (WEDM), Die-sink and Micro-EDM were used as potential approaches to SiNPs production in this paper. Along with experimental data of SiNPs production concerning WEDM, Die-sink and Micro-EDM, a potential novel method of producing SiNPs using high pressure flushing spark erosion is also being introduced in this paper. The new method holds great potential size and productivity compared to other spark erosion nanoparticle production approaches.

SiNPs production using spark erosion

Debris produced from spark erosion was identified as a viable process of fine powder production typically at micro scale range during 1980s [12]. Application of voltage pulse on 2 electrodes at close proximity in a dielectric fluid produces a spark discharge between them. The electrodes are heated in highly localized regions above their melting temperatures, ejecting molten and vaporized materials from them. These are solidified due to rapid quenching from the dielectric fluid, forcing the debris to solidify into spherical shape due to surface tension [13]. Characteristic aspects of these debris normally attribute with large micro particles mixed with nano sized ones. Larger particles are produced from molten material being re-solidified, while the particles from nanoscale region are assumed to be re-solidified from vapor state.

Commercialized EDM should not be mistaken with experiments related to spark discharge in gaseous environment[8]. Although both use spark discharge as the mechanism of material removal, their setups are vastly different, specifically on dielectric and electrodes. These are near-dry gas-dielectric based discharge processes that have proved to produce NPs of high purity and ultrafine size (5-50nm). However they are not good at processing semiconductors. This is due to high resistance of semiconductor electrodes and processing is hampered if semiconductor electrodes of same types are used. Even by using boron doped samples, the maximum productivity rate of SiNPs shown for Si-Si electrode setup is very low, approximately 1mg/h [8]. With low productivity as well as complexity of the set-up, this method is not suitable when it comes to industrial scale productivity.

Experimental

There are several methods of spark erosion based EDM processes, such as Wire-EDM (WEDM), Die-sink EDM, Micro-EDM and every one of them has ability to produce NPs in debris form. However size distribution differs vastly from one another, as well as energy consumption and extraction purification processes. The machining centre in NUAA consists of all these 3 types of EDM machines, which were used to machine heavily doped Si ingot in order to produce respective samples of debris particles. The working parameters of machining processes are given below in table 1.

TABLE1 WORKING CONDITIONS FOR SPARK EROSION PROCESSES

Type	Tool electrode	Working fluid	Open voltage(V)	Peak current(A)	Pulse duration(μs)	Flush Pressure (MPa)
WEDM	Copper wire	Kerosene(mix)	120	30	30	0.1
Die-sink	Copper electrode	Kerosene	120	30	30	0.05
Micro-EDM	Copper electrode	Kerosene	90	5	0.5	0.01
High Pressure	Copper tube	Deionized Water	100	30	1	0.8

Since the debris particles consists of both micro and nano sized constituents, as well as the tool and workpiece electrodes being different, second part of this experimental consists of separating impurities from the NP. This is done with the combination of KQ3200B Megahertz ultrasonic bath and 6 pocket ANKE-TGL-10B Centrifugal separator. The raw debris sample produced from kerosene based dielectric consists of the following impurities: (i) carbon produced from pyrolysed kerosene (ii) Tool material solidified from vapor state (iii) Solidified tool material from molten state (iv) Solidified workpiece material from molten state.. In case of (i), attempt was made to remove the carbon impurities by use of suspension method, using $ZnBr_2$ and separating lamella structured carbon impurities from the spherical shaped residue. However some of the ultra fine SiNPs that might have agglomerated on the carbon particles may also got removed from the test sample. As for (ii) it is extremely difficult to remove such nanoscale impurities using centrifuge from other SiNP (by physical means). For (iii) and (iv) an attempt was made to physically separate the larger particles from the smaller using centrifuge.

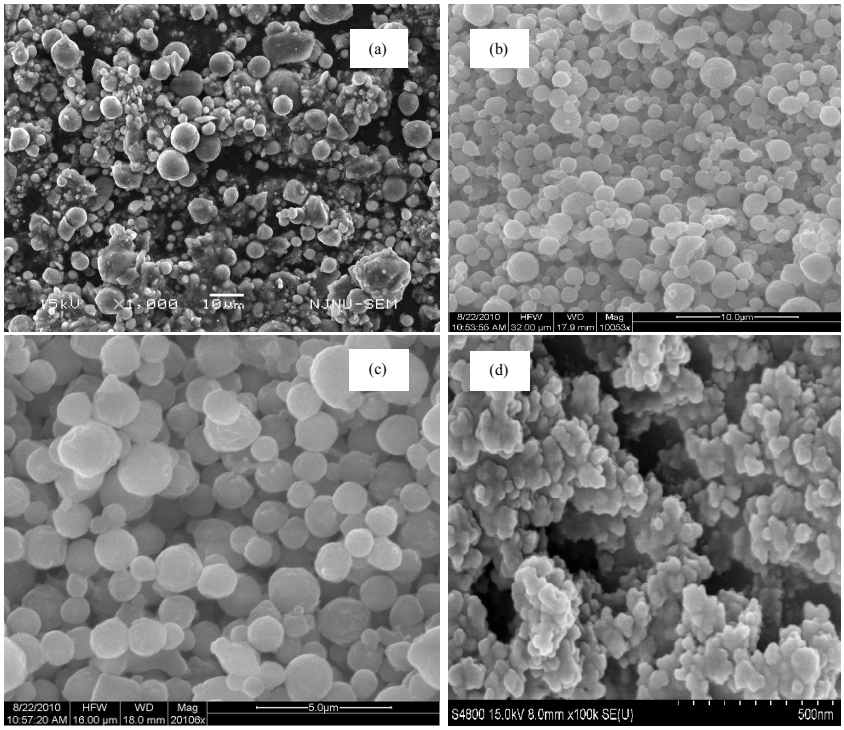

Fig. 1 SEM images showing samples from (a) WEDM (b) Die-sink (c) Micro -EDM and (d) High pressure flush spark erosion

The process of centrifugation is carried out after suspension method, the sample is dispersed using ultrasonic vibrating machine, after which it is mounted on a centrifugal machine. Spun at 4000rpm, the large debris were separated from the smaller ones. The smaller particles floating in the test tubes were all then transferred to a new container and left for 24hrs to settle down. After that the excess liquid was siphoned off and the sediment was extracted by centrifuging once again at 10000rpm and treated to ethanol for SEM testing. For SEM tests, the samples were sputter coated using Baltech SCD 500 sputter coater, and were mounted on Hitachi S-4800 SEM machine.

Result and Discussion

Size distribution for the debris produced by WEDM (Fig 1a) is very uneven, with too many large (5-10μm above) spreading around smaller particles of 800-900 nm. Extraction and purification of debris particles is very difficult for WEDM due to the fact that the dielectric is a special liquid made from mixture of different solvents, most of which are insoluble. Hence during centrifugal separation there is a strong chance of ultra nanosized particles to get washed away along with impurities, suggesting this is not good mechanism for nano production.

For Die-sink EDM (Fig 1b), size and shape distribution improves compared to WEDM. Size distribution is still very uneven, containing large spheres of around 1.5-2 μm while smaller ones range between 500-700nm. Equating E=VIt (V= open voltage, I= current, t= pulse duration), the spark energy for the process can be calculated, using voltage 120V, peak current 30A, time is 1 micro seconds. Hence energy dissipated during discharge is 3.6μJ, while productivity is 0.1g/hr. For the Micro-EDM (Fig 1c), the size and shape distribution doesn't differ much, compared to Die-sink. The size distribution was between 500-600nm and the shape distribution was evenly spherical. The spark energy for this system was (V=90V, A=5A, t = 0.5μs) 0.2 μJ. The productivity was approx 0.02g/hr. Hence the samples produced from these 3 systems are not in accordance with the general nanoparticle dimension of less than 100nm and hence cannot be termed as nanoparticles. In comparison to the research works that has been undertaken on various types of spark discharge/erosion approach to NPs generation, a new system with PLC automated spark erosion machine has been developed in our labs at NUAA. This system is a cross breed between Die-sink and Small Hole-EDM that consists of a copper hollow tube of 1mm and dielectric used is deionized

water. When the machine is initiated the tool rotates and sprays deionized water at 0.8MPa pressure on the machining region, sinking in and initiated spark to erode the silicon ingot. Processing conditions were Voltage 100V, Current 30A; pulse 1µs duty cycle of 2, hence average spark energy calculated is 3µJ. The system is submerged in deionized in order to engage both pouring and submerged flushing, increasing machinability.

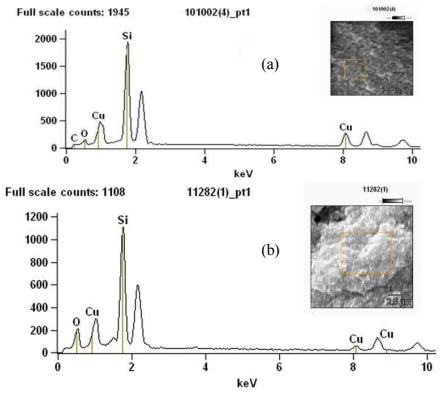

Fig 2 EDS of sample from (a) Micro EDM (b) High pressure flush spark erosion. Notice that the sample produced from kerosene based dielectric contains carbon and copper impurity while deionized water contains only copper oxide.

Due to the high flushing rate of this system, the name given to this prototype machine is High Pressure Flush Spark Erosion. SiNPs comprising an average size of 50nm (Fig 1d) were generated with an average productivity of 1.5g/hr, while EDS (Fig 2b) scanning indicated high Si-based material purity. The size of the nanoparticles achieved was 10-15 times smaller than that of Micro/Die-sinking EDM and with higher productivity. The size is with accordance with the general dimension of nanoparticles (i.e. within 100nm). However the NPs are highly agglomerated, hence research is underway on dispersing the particles by introducing in the system megahertz ultrasonics machine as a source of additional energy during the machining. [14] Also according to EDS results, amount of copper(II)oxide (CuO) impurity seems to be on the higher side, hence further research is required on acquiring a suitable purification process, which is still a semi automated process with combination of ultrasonics and centrifugation.

Conclusion

A comprehensive outlook has been undertaken in this paper to discuss various SiNPs production processes in form of spark erosion. EDM processes such as WEDM, Die-sink and Micro -EDM were carried out on boron doped silicon ingot and corresponding samples were produced and tested under SEM. Additionally a new form of spark erosion process namely High Pressure Flush Spark Erosion has also been introduced which is a cross-breed between Die-sink and Small Hole-EDM. SEM images show SiNPs diameter of 50nm formed from the new system, as well as productivity of 1.5g/hr. Experiments indicated that Die-sink, having higher pulse rate, gave higher productivity however it also consists of similar size distribution with lower pulse rate process (Micro-EDM). This hints that controlling size at nano-scale may not be possible by controlling electrical parameters. Whereas using pressure flush rate with deionized water, the new system was the only liquid dielectric based spark erosion approach that achieved to produce particles in accordance to general nanoparticle dimensions (less than 100nm). This denotes that controlling the flushing pressure of dielectric fluid may be the key to control resultant particle size. Note that although WEDM also consists of fairly high flush pressure, due to cumbersome purification process the resultant sample hardly show any debris at nanoparticle range. However major drawbacks of the high pressure system consist of agglomeration and semi-automated purification process, hence further research is needed for improvement.

Keywords: Stainless steel sheet,Cold metal transfer,Welding parameters,Microstructure

Abstract: Cold metal transfer (CMT) process is a modified inert gas metal welding process,which characterrizes of low heat input and no spatter welding comparing with traditional GMAW process.In this paper,research of the CMT welding features of stainless steel sheet has been conducted.The effects of welding parameters including wire feed rate,welding speed and arc-length modification coefficient on mechanical properties and surface morphology were investigated.In addition,optical micrograph(OM) and scanning electron microscope(SEM) were used to analyze the weld microstructure,and microstructural characteristics were discussed as well.In the end,the optimum welding parameters which were used in real production and achieved good effect were obtained by means of orthogonal experiment.

Introduction

With the rapid development of rail transportation in recent years, Stainless steel have been used in the manufacture of railway vehicle widely[1].Stainless steel vehicle bodies with its advantages such as light weight,low energy consumption and good corrosion resistant have been the first choice for railway passenger vehicles[2].In order to reduce pollusion and save energy,it is attractive to make vehicle bodies lighter though using stainless steel sheet with thin thickness [3].Due to stainless steel sheet is easy to bum through,some especial welding process were required to reduce heat input such as AC pulsed MIG,spot welding and laser welding[4].B. Gulenc etc have studied 304L stainless steel with MIG process in different parameters,and its conclusion that though MIG process has many advantages,the negative effects were the HAZ grain coarsening and smooth transitional droplet is hard to obtain[5].

In this article,research was conducted to weld in corrugated sheet on the top of vehicle body to side roof.The thickness of corrugated sheet is 0.6mm and the thickness of side roof is 1.5mm.To achieve to weld the lap of longitudinal seam successfully,many efforts have been made[6].

Currently,tradition methods in the industry were using gas metal arc welding process with the shielding gas including 97%Argon and 3%Oxygen to make the weld joint.GMAW actual welding surface morphology of stainless steel vehicle body is shown in Fig. 1.

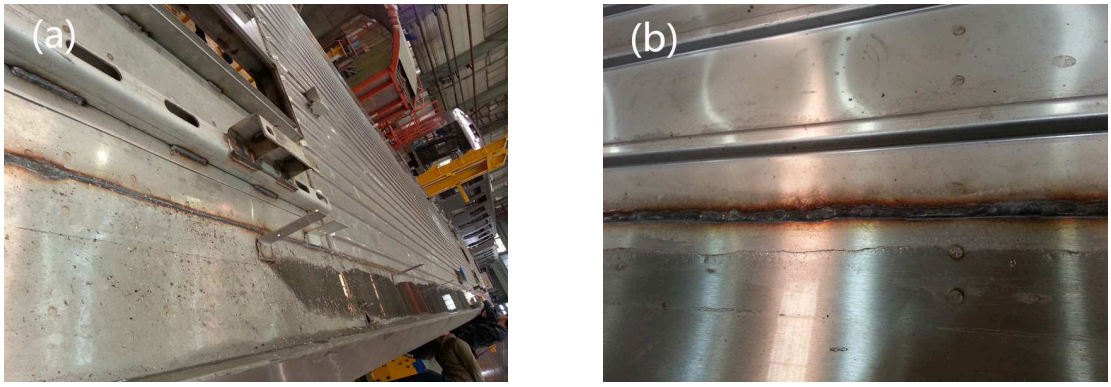

Fig. 1 Surface morphology of stainless steel vehicle body with traditional process

Apparently,GMAW welding surface morphology showed that the welding quality is not ideal.Defects including air hole and overheat were found in welded joint.So it is difficult to achieve the sound weld with acceptable weld strength of the welded joints and smooth surface morphology.Welding quality become a key problem which should be resolved.To the problem,Welding process have to be improved.By a large number of investigation and study,GMAW process is replaced by cold metal transfer(CMT) process.

The arc characteristics of the CMT process

The CMT process is a modified metal inert gas welding process which was invented by Fronius company[8].CMT was developed on the basis of research on joining steel to aluminum alloy,SFI and micro-connection technology.R.Cao andZ.Feng etc have made titanium-copper lap welded joints by cold metal transfer technology[9].CMT is wildly applied to join the dissimilar metals and also used to weld thin metal sheet.

The arc shape variation of the CMT process as shown in Fig. 2 .In one cycle,the brightness of the arc in the picture is low except two frames at the beginning of the cycle.The wire retraction motion assists droplet detachment during the short circuit, thus the metal can transfer into the welding pool without the aid of the electromagnetic force.CMT process has three differences comparing to traditional metal inert gas welding process[10]:

(1)The motions of the wire have been integrated into the welding process and into the overall control of the process in the first time.

(2) The current of short circuit is close to zero during the short circuit.

(3)The wire retraction motion assists droplet detachment from parent metal.

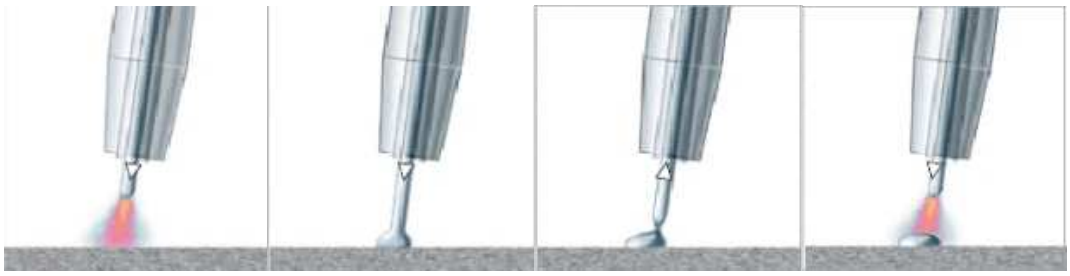

Fig.2 Arc shape variation of the CMT process

The wire retraction motion helps droplet detachment during the short circuit,thus the metal can transfer into the welding pool without the aid of the electromagnetic force.Then the heat input is decreased greatly and the welding process could almost without spatter[11].Thereby the joint can deduce welding deformation to achieve the mechanical performance.

Experimental set-up

The selected materials was A304 stainless steel which is a kind of austenite stainless steel.The welding wire was selected 308LØ1.Table 1 shows material and filler wire specified composition values.The sheets in thickness of 1.5mm were cut into blanks with dimensions of 100×200mm and the corrugated sheets with thickness of 0.6mm were cut into blanks with dimensions of 100mm×200mm.Fig. 3 shows the schematic of the welding configuration.

Table 1 Material and filler wire specified composition values

Material	C	Mn	P	S	Si	Cr	Ni
A304	0.08	2.00	0.045	0.030	1.00	18.0-20.0	8.0-11.0
ER308L	0.03	1.80	0.015	0.008	0.60	20.0	10.0

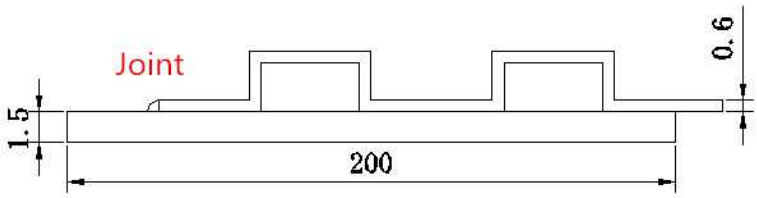

Fig. 3 Schematic of the welding configuration

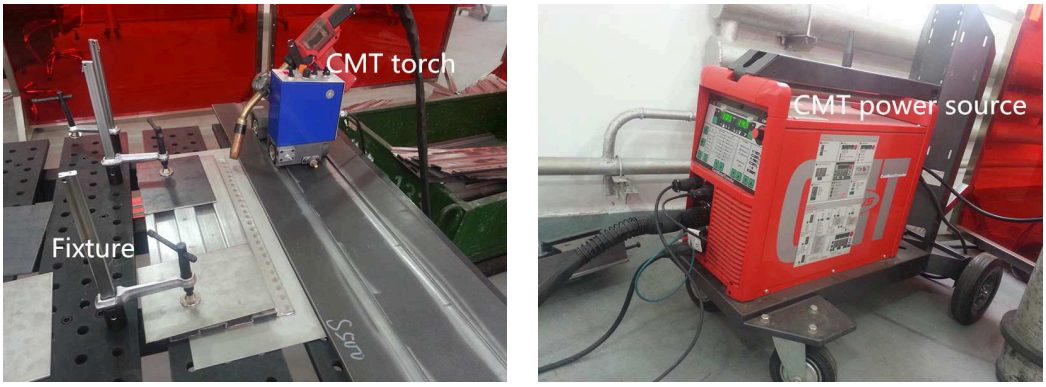

Fig. 4 Experimental set-up

The CMT equipment model used in this study is TransPuls Synergic 2700.As shown in Fig. 4 ,It is the environment of experimental set-up.When the leftward welding method was adopted,97.5%Argon and 2.5%carbon dioxide was used as the shielding gas at a flow rate of 28.5L/min.

Considering the CMT process parameters of welding equipment with expert system,welding current and welding voltage were directly controlled by wire feed rate.Hence,three factors were investigated included wire fee speed,welding speed and arc-length modification coefficient[12].

The wire feed rate ranged from 6m/min.to 11m/min.,in 1m/min. step.and the welding speed was in the range of 360mm/min.-680mm/min.,every step is 80mm/min.Then arc-length modification ranged from－25% to 25% in step of 5%[13].

Results and discussion

Microstructural examination. After the welding, the welds were sectioned into blanks with dimensions of 10mm×20mm,polished and etched for microstructure analysis.Optical microscopy(OM) and scanning electron microscope(SEM) were used investigate the weld microstructure.

Due to a very small heat input from the CMT welding,the distortion was not observed in the weld,and the HAZ zone was narrow comparing with traditional fusion welding.In the macroscopic view,as shown in Fig. 5(a) .The welding line of weld metal and base metal was a stretch of v-shaped contour.The crystallizing morphology on the weld seam was equiaxed grains and dendrites and that on the fusion area were columnar crystals.Crystals on the weld appeared in growth to the weld center,and coarse grain size of austenite in HAZ was relatively uniform.

Further studies on CMT welding joint microstructure morphology by using SEM.As shown in Fig. 5(b),Microstructure morphology is more distinct and the heterogeneity of grain size nearby the fusion line is obvious.Base metal grain with dimensions of 20 microns to 40 microns.The fusion zone is only about 150 microns width due to small heat input from the CMT welding.

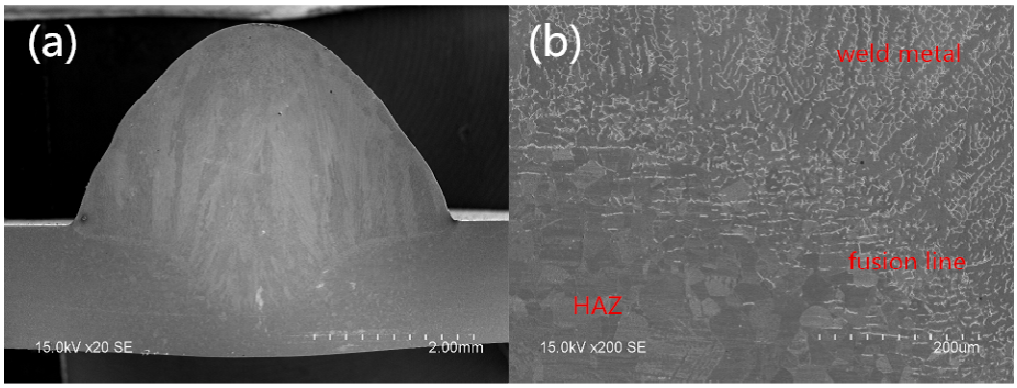

Fig. 5 Microstructure characteristics of joint

Effect of wire feed rate. According to the actual needs,wire feed rate selected ranged from 6mm/min.to 11mm/min,in step of 1mm/min.As shown in Fig. 6 ,the cross-sectional views of the welds obtained in different wire feed rate.When wire feed speed is low,such as 6mm/min.Weld bead presents the characteristic of the high reinforcement and the narrow weld width.But With the improvement of wire feed rate,the weld width and reinforcement increase gradually.It is need to explain that if wire feed rate is further improved,especially exceed 9m/min.,variation of CMT weld appearance is not very obvious.Analysis the reason,when wire feed rate exceeds a certain value,welding current growth begin to play a major role in weld appearance morphology.

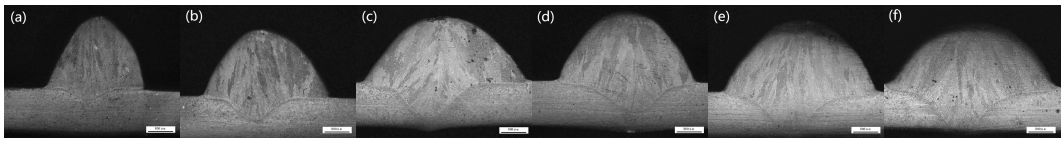

Fig. 6 Cross-sectional views of the welds obtained in different wire feed rate
(a:6m/min.b:7m/min.c:8m/min.d:9m/min.e:10m/min.f:11m/min.)

Effect of welding speed. For cold metal transfer (CMT) welding process,welding speed is a influencing factor corresponding to the welded quality and appearance.Six wire feed rate parametersincluding360mm/min.,440mm/min.,520mm/min.,600mm/min.,680mm/min.,760mm/min .were selected.As shown in Fig. 7 ,the cross-sectional views of the welds obtained in different welding speed.With the improvement of welding speed,it means that decrease of the deposited metal mass per second.Hence,the weld width of weld deposited metal showed a trend of gradual decline.With the increase of welding speed,weld reinforcement and weld penetration is smaller while increased welding speed.

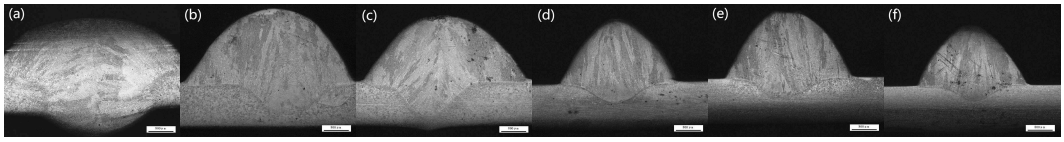

Fig. 7 Cross-sectional views of the welds obtained in different welding speed (a:360mm/min.b:440mm/min.c:520mm/min.d:600mm/min.e:680mm/min.f:760mm)

Effect of arc-length modification coefficient. As shown in Fig. 8 ,cross-sectional views of the welds obtained in different arc-length modification parameters.We selected five parameters including－25%,－15%,－5%,＋5%,＋15%and＋25%.The CMT welding quality and appearance morphology was investigated while different arc-length modification parameters.With arc-length modification changed from small to large,weld width presented a gradually increasing trend,But variation of weld reinforcement was not evident.Due to adjust arc-length modification parameter,there were no significant changed in current and greatly changed in voltage.therefore,The current is the main factor of weld penetration,while the voltage is the main factor affecting weld width.

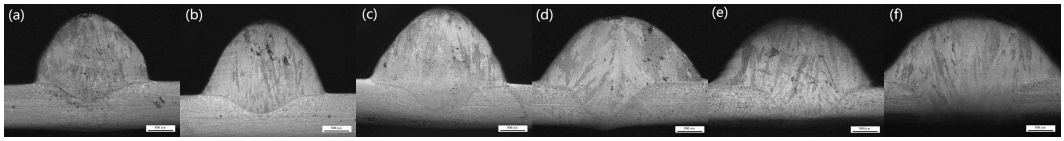

Fig. 8 Cross-sectional views of the welds obtained in different arc-length modification (a:－25% b:－15% c:－5% d:5% e:15% f:25%)

Conclusions

Based on the experimental results and discussions,conclusions were drawn as follows:

(1)The stainless steel sheet was successfully welded by cold metal transfer (CMT) process. Experiment achieved the sound weld with acceptable weld strength of the welded joints and smooth appearance.

(2)Cold metal transfer (CMT) has many potential applications due to its advantages, such as limited heat-affected zone and welding process with no spatter.Practical application shows that the characteristics of CMT make itself feasible in stainless steel railway vehicle manufacture.

(3)By single factor and multifactor orthogonal experiment,it is concluded that the fine weld bead can be obtained under the following parameters: welding current was 99A,welding voltage was 10.5V,wire feed rate was 8m/min,welding speed was 520mm/min,the arc-length modification coefficient is 5%.

Keywords: Energy consumption, Porcelain, Modeling, Operating condition

Abstract. Porcelain produce is a very high energy consumption process. According to total energy balance analysis, a variety of operating conditions are analyzed for effect of net energy consumption. One real porcelain plate produce process is introduced as the reference case. Operating conditions are defined in three parameters, which are air excess number, fuel distribution and solid mass ratio. A simplified model based on finite difference method (FDM) is solved to calculate axial gas and solid temperature profiles and net energy consumption. The net energy consumption in porcelain produce is calculated and discussed in quantity with three operating conditions above separately. Finally, it is concluded that net energy consumption is higher with bigger air excess number and solid mass ratio, while fuel distribution will have no influence on net energy consumption.

Introduction

Porcelain is one of materials commonly seen in our daily life. According to the material properties differences, the porcelain is one kind of ceramic product. Generally, the energy consumption range of ceramic produce process is from 2.3 MJ/Kg to 50 MJ/Kg. Especially; the thermal efficiency of whole process is also very low, which are about from 33% to 46%. The tunnel kiln is one of main devices to produce porcelain products. More than half percentage of energy is lost to ambient and absorbed by furniture in tunnel kiln. Therefore, energy consumption analysis is a very hot topic these days [1]. Due to the limitation of experimental conditions in the real porcelain factory, the simulation and modeling is the only validated method to predict energy consumption with different operating situations.

In order to produce different porcelain products according to different sintering temperatures and temperature gradient, the real factories also do it by adjust operating conditions. The operating conditions are meanly about burner group operation. However, different operating conditions may cause energy consumption difference. In the following subsections, the simplified model and operating conditions on energy consumption will be discussed.

Total Energy Balance

According to total energy balance analysis, the factors which will affect net energy consumption can be analyzed theoretically. The whole porcelain produce process is assumed as a closed energy system. The mass and energy flows in this system are shown in Fig. 1.

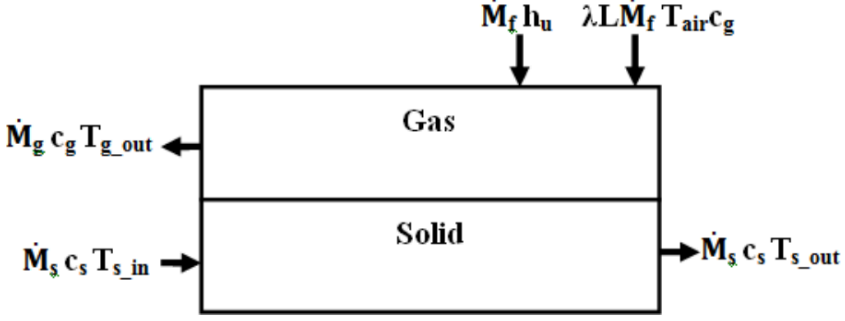

Fig. 1 Simplified energy flows in porcelain produce process

In the graph representation of energy flows, there are gas and solid flows are in parallel and opposite directions. The hot gas flow is from fuel combustion. The net energy from fuel is $\dot{M}_f h_u$ and the energy of air used for combustion is $\lambda L \dot{M}_f T_{air} c_g$. While $\dot{M}_f$ is mass flux of fuel, T_{air} is ambient air temperature, λ is air excess number, L is mass related air demand with Kg_{air}/Kg_{fuel} and c_g is heat capacity of ambient air. After heat transfer from hot gas to cold porcelain products, the gas with energy $\dot{M}_g c_g T_{g_out}$ is sucked out from tunnel kiln with T_{g_out} is gas temperature out from kiln and $\dot{M}_g$ is mass flux of flue gas. For solid, green porcelain products with energy $\dot{M}_s c_s T_{s_in}$, the product with energy after thermal process is $\dot{M}_s c_s T_{s_out}$. With $\dot{M}_s$ is mass flux of porcelain product which is assumed still a constant in whole process. T_{s_in} is temperature of green porcelain product when entering the tunnel kiln and T_{s_out} is temperature of porcelain products out of the tunnel kiln. Due to the simplification, only preheating and firing zones are considered for energy consumption, the T_{s_out} is the sintering temperature.

From the total mass and energy analysis, the energy flows pushed in E_{in} and pushed out E_{out} are defined in Eq.1 and Eq.2

$$E_{in} = \lambda L \dot{M}_f T_{air} c_g + \dot{M}_f h_u + \dot{M}_s c_s T_{s_in} \tag{1}$$

$$E_{out} = \dot{M}_g c_g T_{g_out} + \dot{M}_s c_s T_{s_out} \tag{2}$$

Based on mass and energy balance, the E_{in} must be equal with E_{out}, finally the equation to calculate the net energy consumption for porcelain produce process can be defined in Eq.3 with h_u is fuel enthalpy.

$$E = \frac{\dot{M}_f h_u}{\dot{M}_{prod}} = \frac{(c_s T_{s_{out}} - c_s T_{s_{in}})\dot{M}_s h_u}{[\lambda L T_{air} c_g + h_u - \left(1 + \lambda L\right) c_g T_{g_{out}}]\dot{M}_{prod}} \tag{3}$$

Due to the fuel enthalpy h_u is too much bigger than term $\lambda L T_{air} c_g$ and $(1 + \lambda L)c_g \approx \lambda L c_g$, the whole equation can be simplified as Eq.4

$$E = \frac{\dot{M}_f h_u}{\dot{M}_{prod}} = \frac{(T_{s_out} - T_{s_in})c_s \dot{M}_s h_u}{(h_u - \lambda L c_g T_{g_out})\dot{M}_{prod}} \tag{4}$$

We can conclude which parameters will affect the net energy consumption theoretically from this equation. In real industry, two porcelain product temperatures T_{s_out} and T_{s_in} are fixed, which are sintering temperature and 50℃. The air demand L and energy enthalpy h_u are dependent on fuel. Therefore, two parameters air excess number λ and Solid Mass Ratio (SMR) $\frac{\dot{M}_s}{\dot{M}_{prod}}$ will affect net energy consumption, which is related with operating conditions.

In another way, the fuel distribution (FD) in burner groups can be different in reality. Therefore, the FD can be another operating condition that will be discussed for net energy consumption. Gas temperature in outlet T_{g_out} cannot be known in advance, only modeling and simulation can predict its possible value. Therefore, a simplified model programmed in MATLAB is introduced to adjust operating conditions and calculate T_{g_out}. Finally, the net energy consumption with different cases can be discussed in this simplified model.

Simplified model introduction

The simplified model for porcelain plate production is already developed with finite difference method (FDM) [2]. The differential equations can be solved with two fixed porcelain products temperatures, which are porcelain temperatures before pushing in kiln and sintering temperatures. In the existed model, only preheating zone and firing zone are considered. Because all flue gas is only pushed through these two zones, and no flue gas in cooling zone. It means no energy

consumption in cooling zone. Therefore, this model can be developed further to discuss net energy consumption. The Fig. 2 shows the how the porcelain plate are produced in tunnel kiln.

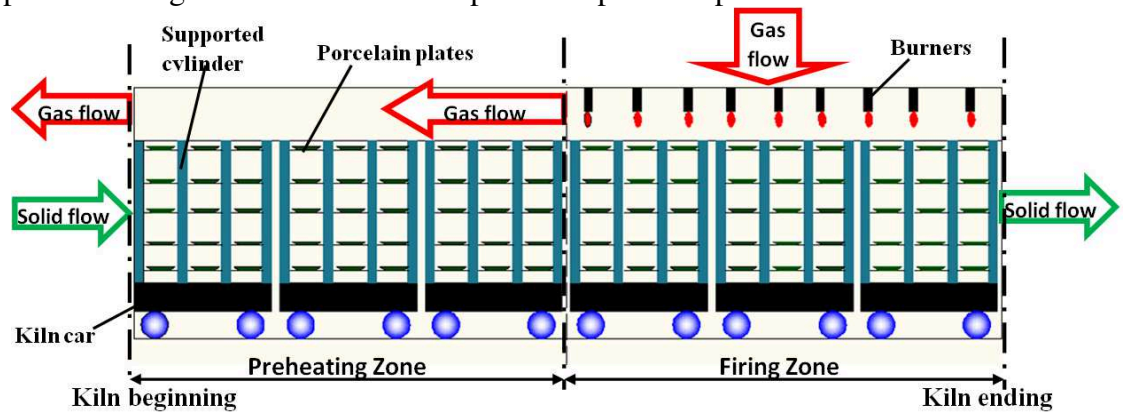

Fig. 2 Brief representation of work principle of porcelain produces

In this model, all porcelain products keep the same temperature with furniture and kiln car. The convective and radiative heat transfers from flue gas to porcelain products are considered. The convection description is from Lorenz's Nusselt function [3]. All constructions of tunnel kiln are the same as the real existed kiln. The detailed construction data are shown in Table 1.

Table 1 Construction data of one real porcelain plate tunnel kiln

Preheating length	8 [m]	Plate diameter	0.26 [m]
Firing length	36 [m]	Sintering temperature	1350 [℃]
Kiln width	1.5 [m]	Net performance	500 [Kg/h]
Kiln height	0.8 [m]	Net energy consumption	14 [MJ/Kg]
Car length	1.9 [m]	Fuel	Natural gas
Plates per car	144 [-]	Burner groups number	9
Solid mass ratio	10 [-]	Gas heat capacity	1100 [J/Kg/K]
Solid heat capacity	880 [J/Kg/K]	Fuel heating value	50.28 [MJ/Kg]

It is already proved this model is available to predict axial flue gas and solid temperature profiles. Therefore, it can also be applied to predict net energy consumption for porcelain produce.

Results and Discussions

According to the energy consumption analysis and model operating condition discussion, there are three main parameters we can discuss. They are air excess number, SMR and FD.

Firstly, the air excess number of nine burner groups can be discussed in four different cases shown in Table 2. Theoretically, air excess numbers of these nine burner groups can be different. In order to make sure all discussions are based on the same standard, only the air excess numbers in the middle three burner groups are variables. From case 1 to case 4, they are varied from 1.2 to 2.4, the mean air excess number is from 1.4 to 1.8. In the first three burner groups, the air excess numbers are exactly one, because oxygen is not allowed in this region. Due to porcelain products temperatures are fixed in the tunnel kiln beginning and ending, only axial flue gas temperature profiles are shown in Fig.3 and net energy consumption are shown in Fig.4.

Table 2 Air excess number in burner groups with four different cases

Burner	9	8	7	6	5	4	3	2	1	**Mean λ**
Case 1	2	2	2	1.2	1.2	1.2	1	1	1	1.4
Case 2	2	2	2	1.6	1.6	1.6	1	1	1	1.53
Case 3	2	2	2	2	2	2	1	1	1	1.67
Case 4	2	2	2	2.4	2.4	2.4	1	1	1	1.8

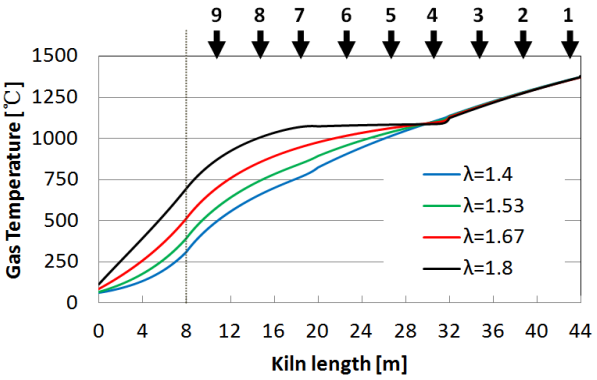

Fig. 3 Gas temperature profiles with different air excess numbers

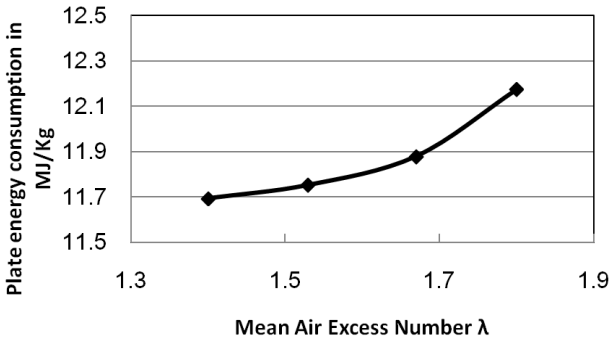

Fig. 4 Net energy consumption curve with different air excess numbers

In gas temperature curves, they are covered absolutely in the first three burner groups region, because the operating conditions are exactly the same. In the following burner groups region, gas temperature profiles are raised higher with bigger air excess number. Because the temperature gradient is related with mass flux of flue gas [4]. Finally, it is shown that net energy consumption increase with bigger air excess number. Because of more energy should be used to heat cold air. However, air excess number does not have a very big effect on energy consumption. There is only about 4% energy consumption increase with about 30% increase of air excess number.

Secondly, different FD is discussed. Fuel is distributed in three different ways shown in Table 3. The sum of fuel percentages in burner groups is 100%. For case 1, less and less fuel is input along gas flow direction. Case 2 distributes fuel in average while case 3 distributes more and more fuel in burner groups. Finally, axial gas temperature profiles are shown in Fig.5 and energy consumption curve is shown in Fig.6.

Table 3 Fuel distribution with different arithmetic progressions

Burner	9	8	7	6	5	4	3	2	1

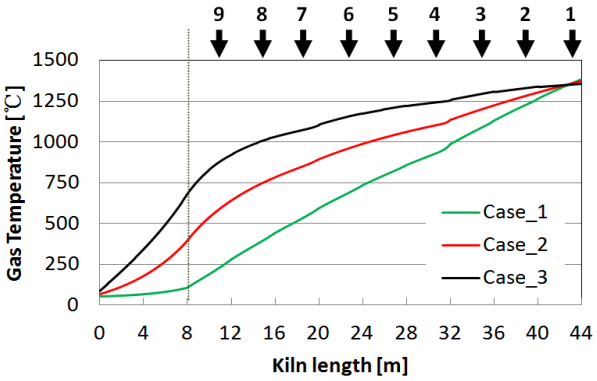

Fig. 5 Gas temperature profiles with different fuel distribution

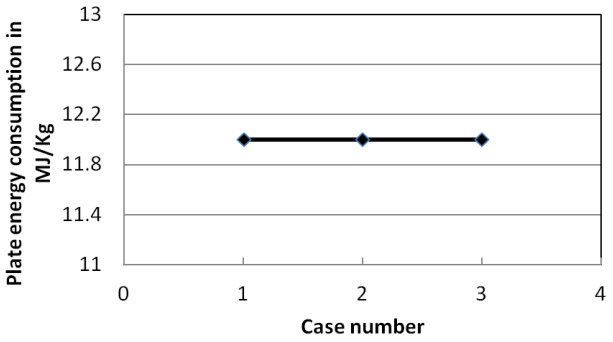

Fig. 6 Net energy consumption curve with different fuel distribution

As seen in Fig.5, gas temperatures in kiln ending and beginning are the same for cases. The flue gas variances during whole process are different with different cases. One important point is shown in preheating zone of case 1 from 0m to 8m, the flue gas temperatures almost keep a constant. It means almost no heat transfer from hot flue gas to cold porcelain products is this region. In reality, the porcelain factories always want more heat transfer in this region and temperature of porcelain product can increase faster. Therefore, the situation of case 3 should be avoided in reality and more fuel should be input in the last burner groups. The net energy consumption profile shows that net

energy consumptions are the same with different fuel distribution. The reason is the same amount of fuel is input in whole process but only with different percentages in burner groups. According to definition in Eq.3, the net energy consumptions must be the same with the same fuel mass flux.

Thirdly, the axial flue gas temperature profiles and net energy consumptions with different SMR are discussed and shown in Fig.7 and Fig.8. The SMR is changed from 4 to 13.

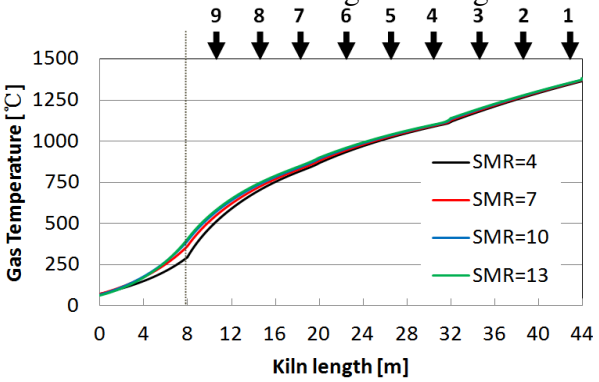

Fig. 7 Gas temperature profiles with different solid mass ratio

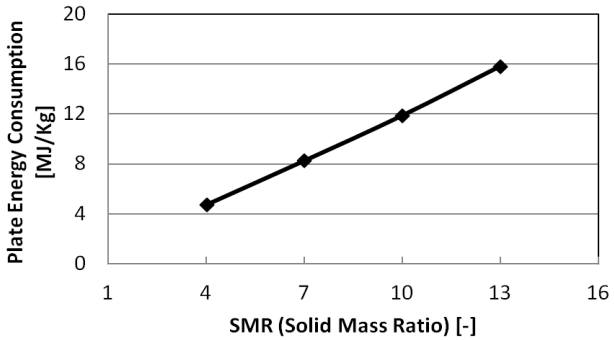

Fig. 8 Net energy consumption curve with different solid mass ratio

As shown in gas temperature profiles, different SMR will have less effect on temperature profiles. As shown in net energy consumption curve, the net energy consumption will be bigger with bigger SMR. According to definition of total solid mass flux, it is the sum of porcelain products, furniture and kiln car. If mass flux of porcelain products is fixed, the mass flux of furniture and kiln car will be bigger with bigger SMR. In these four cases, the mass flux of porcelain product is assumed to be a constant. Therefore, it means more energy is absorbed with heavier furniture and kiln car. The net energy consumption will be three times bigger when SMR is two times bigger [5]. Compared with net energy consumption influence of air excess number, the SMR will dominate the energy consumption influence.

Conclusion

This paper discussed the net energy consumption, which the porcelain plate as an example. The existed model can predict the axial porcelain temperature and calculate net energy consumption. The net energy consumption is discussed with three different operating conditions including air excess numbers, fuel distribution and solid mass ratio. The following conclusions can be obtained:

(1) When porcelain performance is fixed, with bigger air excess number, the net energy consumption will be bigger.

(2) When air excess number and porcelain performance are fixed, different fuel distribution in burner groups will only affect axial porcelain temperature profiles. Moreover, fuel distribution will not affect net energy consumption

(3) When air excess number and fuel distribution are fixed, the net energy consumption will increase with bigger solid mass ratio

(4) In order to produce the certain amount of porcelain products with fixed fuel amount, the lighter furniture and kiln car should be applied.

Keywords: Dissimilar welded joint, Submerged arc welding filled with Ni wire, Transition width, Peak temperature, Holding time at elevated temperature.

Abstract: Aim at the issue that the bending crack is easy to generate inside dissimilar welded joint of low alloy steel and stainless steel, a new process of submerged arc welding filled with Ni wire is put forward. The influence mechanism of filling quantity of Ni wire to the joint of microstructure evolutions and mechanical properties is mainly explored based on the contrast test of non-filling Ni wire and three different filling speeds of Ni wire. The experiment results indicate that, the filling process of Ni wire supplies austenite forming element, and alters heat allocation process of molten pool. The filling quantity of Ni wire is the quantitative parameter, it is used to control the transition width between low alloy steel and weld metal, also to adjust the peak temperature and holding time at elevated temperature of molten pool. When the value of the filling quantity of Ni wire is determined, the problem of bending crack in the fusion zone of low alloy steel can be solved, and also the overheat damage can be eliminated. At the same time, the grains of weld metal and heat affected zone are refined. And on this basis the plasticity, toughness and microhardness of welded joint can be guaranteed.

Introduction

Dissimilar weldments have been widely used in shipbuilding and chemical industry because of reducing fabrication costs as well as the full advantage of each outstanding physical property, such as stainless steel with corrosion and oxidation resistance[1,2]. Although the welding joints of austenite stainless steel (ASS) and low alloy steel (LAS) are often applied in the manufacture of pressure vessels, some weld defects such as dilutions and cracks will generate in the weld metal (WM) and lead to great decrease of properties of the welded joint[3,4]. This is mainly because austenite forming element deficiencies in the fusion zone close to LAS side leads to develop temporary stabilization structure of austenite and martensite[5]. Submerged arc welding filled with Ni wire is a welding process that inserting another filling wire without power supplying in submerged arc welding molten pool. Filling wire can make WM component uniform and control heat reallocation of molten pool reasonably[6]. Submerged arc welding filled with Ni wire is tried to solve the welding problem about the dissimilar joint of Q245R and SUS304 in this paper.

Materials and Experiment

Base metals employed are LAS (Q245R) and ASS (SUS304), arcing wire adopts 4mm diameter ER309, their chemical composition is given in Table 1. Filling wire adopts 1mm diameter pure Ni wire. All of the plates are machined to the same dimension of 300 mm×100 mm×10 mm. The joints were produced in two passes (front and back) using the following parameters: 530A; 35V; and 30m/h welding speed. The front without groove and the back with 90°single-V edge preparation was followed with a root face of 5 mm. To find out the effect of the filling process of Ni wire on microstructure and properties of the dissimilar joint, four type tests are carried out. Their test condition is different, so we can get four different type joints. Type Ⅰ represents the joint without

filling Ni wire; type Ⅱ, Ⅲ, Ⅳ represent the joints on the condition of filling speed of Ni wire is 130m/h, 194m/h, 266m/h respectively. A series of microanalyses and properties tests on these joints are conducted. The mechanical properties tests of welded joints include bending test, Charpy 'V' notch impact test and microhardness measurement. The microstructure characterizations of the dissimilar joints are analyzed using scanning electron microscopy (SEM). The chemical analysis in different zones of weldments is detected employing Energy-dispersive spectroscopy (EDS).

TABLE 1 CHEMICAL COMPOSITIONS OF BASE METALS AND FILLER METALS (WT.%).

Materials	C	Cr	Ni	Mn	Si	Mo	S	P

ER309	≤0.12	23.0-25.0	12.00-14.00	1.00-2.50	0.30-0.65	≤0.75	≤0.03	≤0.03

Results and Discussion

Microstructure

The difference of thermal physical property and electromagnetic property between ASS and LAS, not only makes different temperature of liquid metal in both sides of the molten pool, but also makes the liquidity of molten pool metal, mechanical agitation and electromagnetic stirring effect relatively weak. So the metal in the edge of Q245R molten pool can't blend with the filling metal from arcing wire intensively, result in forming solidification transition layer with certain width close to LAS side. The layer can be described by EDS spectra at interfaces between Q245R and WM, which is shown in Fig.1. The diluting effect of LAS on WM and the fast cooling of the molten pool leads to alloy element gradients near the fusion line[7]. From Fig. 1, the variations in Cr, Ni content decrease gradually. They present evident gradient variation near the fusion zone, and the content of Cr varies more markedly than that of Ni. The concentration gradient curve of Cr and Ni shows that the interface of LAS and WM with a certain width sudden change zone, it is defined as transition width (TW). Although this zone location overlaps solidification transition layer, it expresses the failure location more accurately than solidification transition layer (the zone between type Ⅱ boundary and fusion line)[8,9]. Fig. 1(a) represents EDS spectra of type Ⅰ, and Fig.1(b), (c) and (d) represent EDS spectra of type Ⅱ, Ⅲ and Ⅳ respectively. The TW is maximum in Fig. 1(a), as is seen in Fig. 1(b), (c), (d), the TW is decreased gradually with the filling speed of Ni wire increasing. It make the weak zone of the joint is improved obviously that the Ni wire provides adequate austenite forming element for the organization transformation of LAS on the action of the heat of molten pool and the force of electromagnetic stirring.

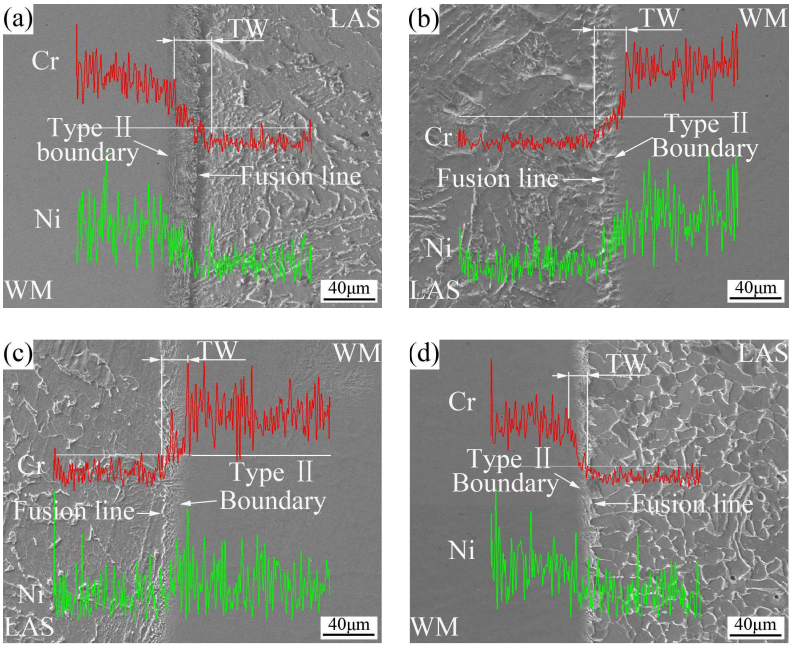

Fig. 1 EDS line scanning across the Q245R-WM interface: (a) type Ⅰ; (b) type Ⅱ; (c) type Ⅲ; (d) type Ⅳ.

The filling process of Ni wire not only provides austenite forming element for the WM, but also changes the heat distribution of molten pool. To reflect its impact on the temperature fields of molten pool, the computer data acquisition system is built. By means of the system, the thermal cycling curve of the center of molten pool is measured, which is shown in Fig.2. NW and FW represents the thermal cycling curve of type Ⅰ and type Ⅳ respectively, the peak temperature of FW is up to 243℃ lower than the NW. t_1 and t_2 represent the holding time at elevated temperature of type Ⅰ and type Ⅳ respectively, the holding time at elevated temperature of FW is 8s shorter than that of NW. This shows that the filling process of Ni wire alters the heat distribution of the molten pool markedly. The change is mainly due to the fact that a part heat of molten pool is used to melt Ni wire. Through controlling the filling quantity of Ni wire, anticipant peak temperature and holding time at elevated temperature can be also obtained.

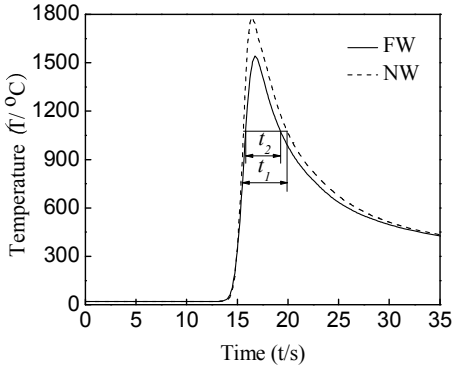

Fig. 2 The thermal cycling curve of type Ⅰ and type Ⅳ.

Reasonable peak temperature and holding time at elevated temperature are the condition precedent of eliminating grain coarsening and obtaining the anticipant microstructure of HAZ. The microstructure of type Ⅰ is shown in Fig.3(a). The HAZ structure mainly is the coarse block ferrites and widmanstatten structures. The HAZ microstructure of type Ⅱ, Ⅲ and Ⅳ is shown in Fig.3(b), (c) and (d) respectively. Apparently, their microstructures are greater improvement than that of type Ⅰ. The difference of the structure between the HAZ and the base metal is decreased, the matrix structure is lamellar pearlite, ferrite distributes uniformly along the grain boundary. And the dimension of grains becomes finer, more homogeneous and rounder with the filling speed of Ni wire increasing. Consequently, the anticipant microstructure of HAZ can be achieved by means of controlling the filling quantity of Ni wire.

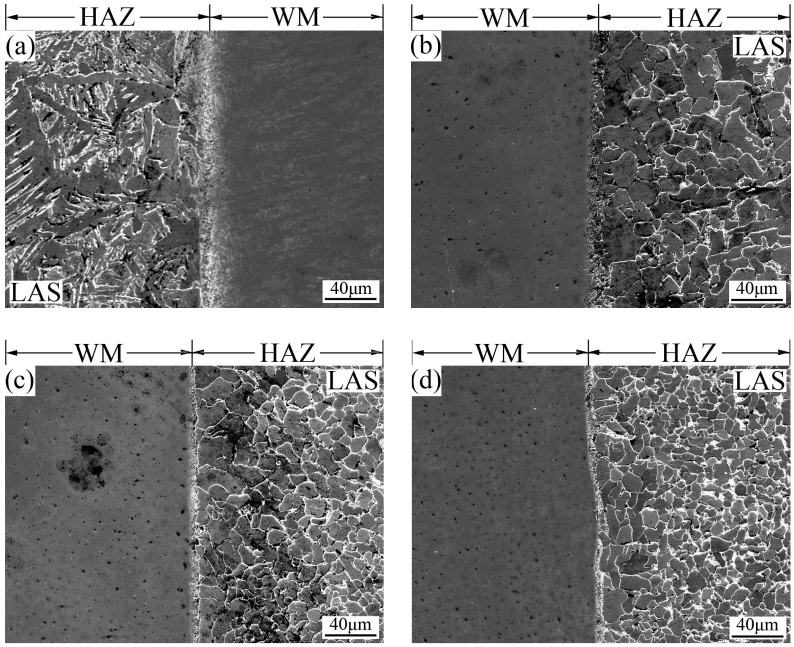

Fig. 3 Microstructures of HAZ in LAS side: (a) type Ⅰ; (b) type Ⅱ; (c) type Ⅲ; (d) type Ⅳ.

Mechanical Properties

Root bending tests are accomplished for the joints of four type tests. In all joints of the test, the cracks with no exception appear in the fusion zone close to LAS side. This indicates that the zone is the weak location of the dissimilar welded joint. In the four type tests, whether generating the crack or not and the length of the crack are selected as evaluation indexes. The two indexes are measured and shown in Table 2 and Fig.4. The joints of type Ⅰ, Ⅱ and Ⅲ almost generate the crack, while only the two of the twenty joints appear the crack for type Ⅳ test. This shows that the joint plasticity of the type Ⅳ is better than the others. The crack length is closely related to the filling speed of Ni wire. In Fig. 4, WE1, WE2 and WE3 represent the number of samples. The crack length of type Ⅰ, Ⅱ, Ⅲ and Ⅳ is contrasted in each sample. The fact observed from Fig. 4, the crack length is obviously shortened with the filling speed of Ni wire increasing. Apparently, the shorter crack length, the better joint plasticity is. The austenite phase increased and the brittle nitrides phase reduced with the filling speed of Ni wire increasing. This is a major reason for the improvement of plasticity and crack resistance. Therefore, the plasticity of welded joint can be guaranteed by means of the filling process of Ni wire.

TABLE 2 THE BENDING TEST RESULTS OF WELDED JOINT.

Test type	Number of joint [pcs]	bending angle [°]	Number of generating the crack [pcs]
Type Ⅰ	20	180	20
Type Ⅱ	20	180	18
Type Ⅲ	20	180	18
Type Ⅳ	20	180	2

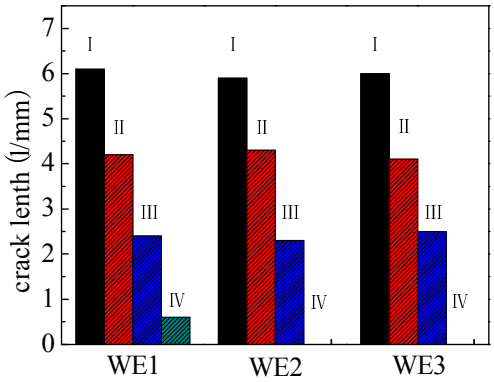

Fig. 4 Crack length of root bending test.

The Charpy impact test of LAS in HAZ is conducted. The relation curve between the filling speed of Ni wire and impact energy is shown in Fig.5. The data point is the mean, which is taken from running each test three times. The value of impact energy increases with the filling speed of Ni wire increasing. The filling process of Ni wire also brings a welcome change to microhardness of the joints. This change can be indicated from the microhardness curve of FW and NW in Fig.6. The filling process of Ni wire not only decreases hardness of HAZ and WM obviously, but also makes the width of HAZ narrow. Furthermore, it is for the filling process of Ni wire that carbon migration near fusion line is availably inhibited. This makes the change range of hardness in fusion zone decrease. These changes are advantage to improve mechanical properties of the dissimilar joints.

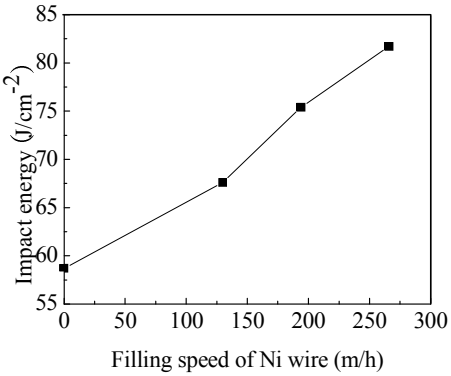

Fig. 5 Relationship between impact energy and filling speed of Ni wire.

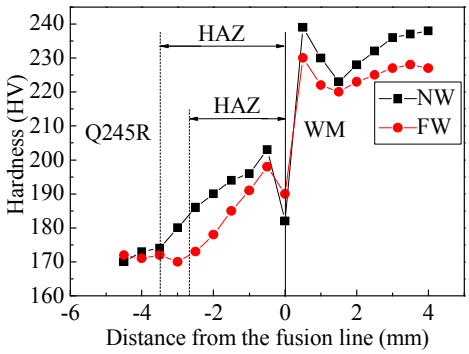

Fig. 6 Microhardness profile across the LAS-WM interface.

Summary

When LAS and ASS are connected by fusion welding, the existence of solidification transition layer is the mainly reason for bending property degradation. The filling of Ni wire supplies austenite forming element when LAS melt to form WM. When the value of the filling quantity of Ni wire is determined, the value of TW can be controlled within the limits of mechanical properties. If so, the problem of bending cracks can be solved.

When the Ni wire inserts molten pool to melt, it will absorb part heat to result in altering temperature fields of molten pool. So, reasonable peak temperature and holding time at elevated temperature of molten pool can be obtained by controlling the filling quantity of Ni wire. On this basis, microstructure and mechanical properties of welded joint can be guaranteed. Submerged arc welding filled with Ni wire puts forward to a new idea for the joint of LAS and ASS.

The Behavior of Second Phase Particles in a Ti-Nb Microalloyed Steel During Welding Thermal Cycle

Maoai Chen[1a], Chuansong Wu[1b]

MOE Key Lab for Liquid-Solid Structure Evolution and Materials Processing, Shandong University, Jinan 250061

[a] chenmaoai@sdu.edu.cn, [b]wucs@sdu.edu.cn

Keywords: Second phase particle, Microalloyed steel, Weld thermal cycle

Abstract. The behavior of second-phase particles in a microalloyed steel during weld thermal cycle has been investigated using analytical electron microscopy. All the particles in the base metal contains Nb and Ti, and the Nb weight fraction of the analyzed particles ranged from 0.22 to 0.85. During the heating stage of the weld thermal cycle, the small particles which were rich in Nb disappeared through complete dissolution and the large particles survived the weld thermal cycle with Nb weight fraction decreased. With a high cooling rate ($t_{8/5}$ no greater than 60s), only heterogeneous re-precipitation occurred during cooling. With a low cooling rate ($t_{8/5}$ = 120s), homogenous re-precipitation also occurred, producing a large number of small Nb-rich particles during cooling.

Introduction

During welding of HSLA steel, austenite grain growth will inevitably results in poor toughness of the coarse grained heat-affected zone (CGHAZ).One method of alleviating this problem is to introduce fine dispersed particles, such as TiN, TiNb(C,N) into the steel. These stable second phase particles are expected to pin the grain boundaries, thus restricting austenite grain growth [1-4]. However, the second phase particles in the microalloyed steel can dissolve, coarsen and re-precipitate during welding, which affect the size, quantity and distribution of the particles, and therefore affect the impact toughness in the CGHAZ. Hence, it is important to understand the response behavior of the second phase particles to the welding thermal cycle.

In this paper, the morphology, quantity, size of second phase particle in Nb, Ti and Ti-Nb microalloyed steels and their simulated CGHAZ were investigated so as to understand change of these second phase particles in the weld thermal cycle.

Experimental

The composition of the microalloyed steel used is shown in Table 1. Specimens with dimension of 10.5mm×10.5mm×55mm were cut from the steel plate and subjected to CGHAZ simulation by using a Thermorestor simulator. The peak temperature (T_p) of weld thermal cycle was 1350°C, the heating rate was 96.6°C /s, and the cooling times from 800°C to 500°C ($t_{8/5}$) were 16s-120s.

TABLE 1 THE COMPOSITION OF TI-NB MICROALLOYED STEEL USED/%

C	Mn	Si	Nb	Ti	Al	N	S	P
0.13	1.36	0.35	0.023	0.017	0.030	0.013	0.005	0.016

The procedure described in reference 5 was used to fabricate carbon replica. The samples used in the carbon extraction replica experiment were cut from the center of the simulated specimen.

The morphology, quantity, and size of the particles on the carbon replica were examined by H-800 TEM, the particle compositions were also investigated by the energy dispersive X-ray spectroscopy (EDX). More than 150 fields were examined and the number of particles analyzed was at least 1000 for every specimen.

Results and Discussion

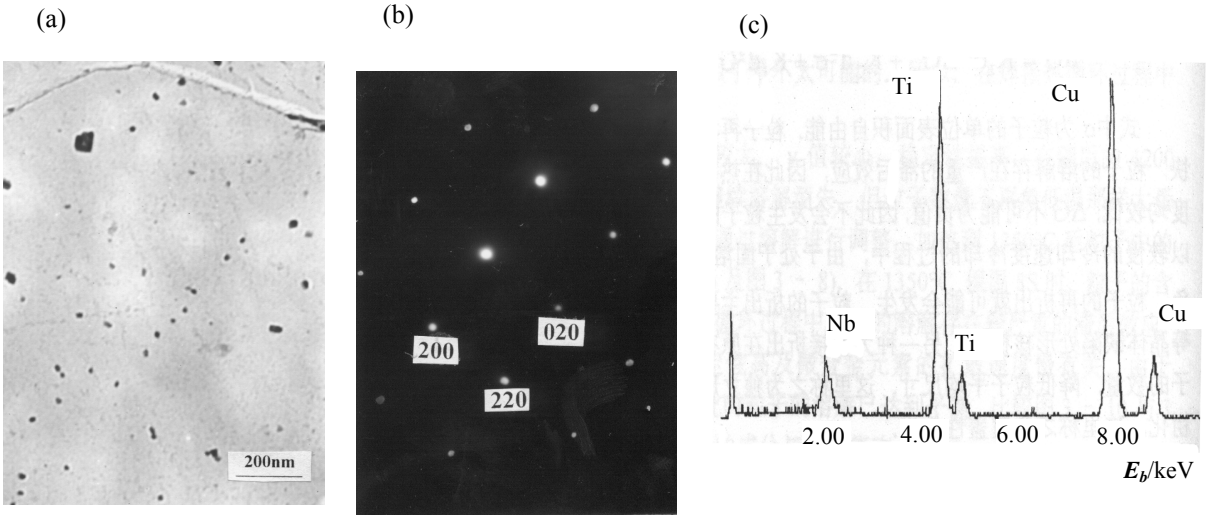

Fig. 1 TEM morphology (a), diffraction pattern (b) and EDX spectrum (c) of particles in Ti-Nb microalloyed steel

Fig.1 shows the typical morphology, diffraction pattern and EDX spectrum of particles in the base metal. Most of the particles are roughly spherical and only a few of them are roughly cubical (see Fig.1a). Electron diffraction analysis revealed that particles possessed a face center cubic structure (see Fig.1b). The lattice constant measured was 0.43502nm, which was closed to those of TiC, TiN, NbC, NbN. EDX analysis indicated that all the particles contains Ti and Nb. These particles are complex carbo-nitrogen compound of the form Ti_xNb_{1-x}, (C_yN_{1-y}).

Fig.2 shows the particle size distribution and composition in the base metal, where D is the average diameter of particles, N is the particle number per unit area (μm^2). Most of the particles is less than 20nm in diameter, the average diameter is just 14.2nm, and the particle number per unit area is about 42.88 /μm^2(Fig.2a). The relative weight fraction of Nb ranges from 0.22 to 0.85(Fig.2b). Small particles less than 50nm tend to be rich in Nb (Nb/(Nb+Ti) >0.5), and large particles greater than 50nm tend to be rich in Ti (Nb/(Nb+Ti) <0.3).The Ti and Nb content of the particle vary with its precipitating temperature[6]. During cooling of the steel, the particles precipitating at high temperature are rich in Ti, and those precipitating at low temperature rich in Nb. The Ti-rich particles precipitating at high temperature have more time to coarsen, thus tending to be larger, the Nb-rich particles precipitating at low temperature have less time to coarsen, thus tending to be smaller.

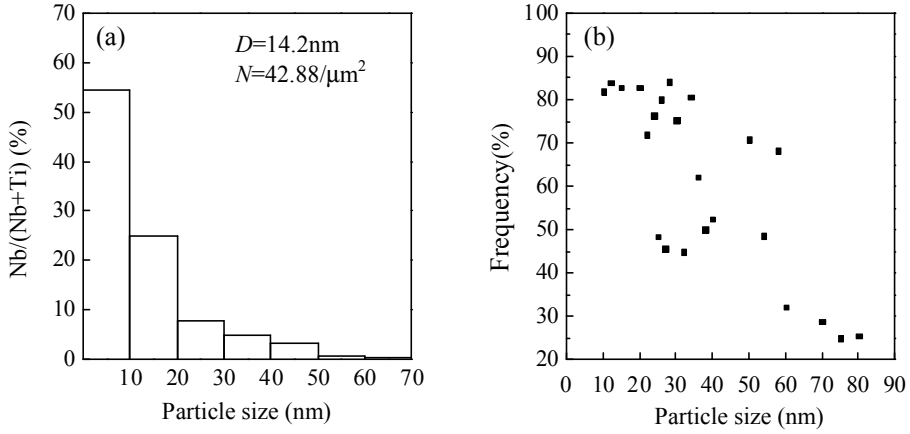

Fig. 2 Size distribution (a) and composition distribution (b) of particles in the base metal

Fig.3 shows particle morphology, size and composition distribution in specimen heated to1350℃ at a heating rate of the weld thermal cycle and then quenched into water after 2s at 1350℃. After heating to 1350℃, all the particles have a cubical morphology, see Fig.3a. The particle number per unit area changes from 42.88 to 3.144, the average particle diameter changes from 14.2nm to 24.6nm,

see Fig.2b. While the Nb weight fraction of the particles decreases considerably, falling in a narrow range from 0.06 to 0. 16. These all suggest that the small Nb-rich particles dissolve completely, the large particles dissolve partially accompanied by a composition change from Nb-rich to Ti-rich during heating stage of the weld thermal cycle.

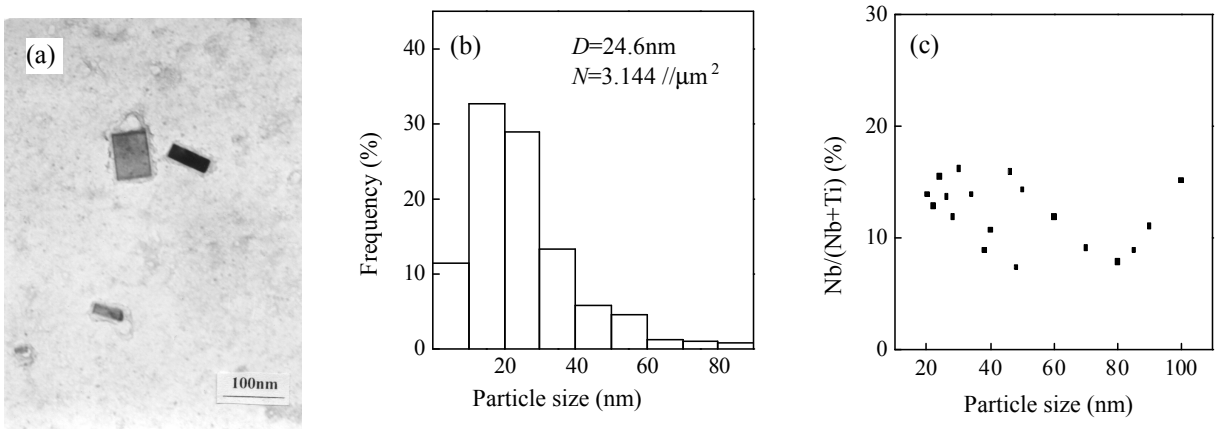

Fig. 3 Particle morphology (a), size distribution (b) and composition distribution (c) in specimen heated to 1350°C and then water quenched

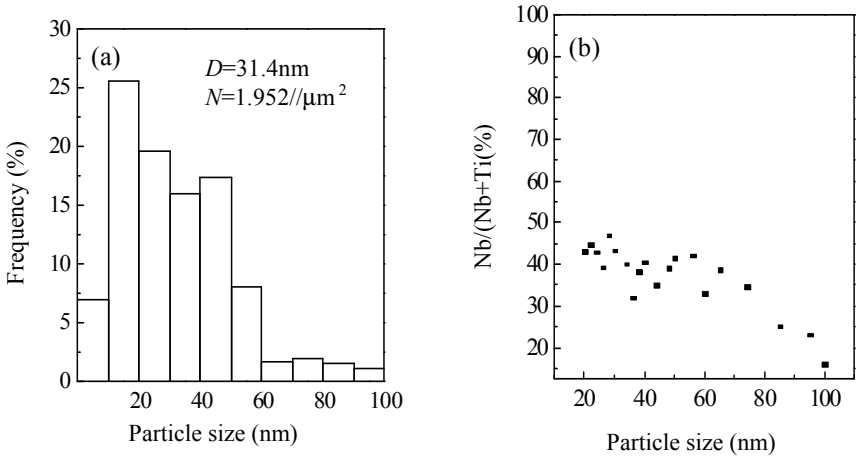

Fig. 4 Particle size distribution (a) and composition distribution (b) after weld thermal cycle with a $t_{8/5}$ of 16s

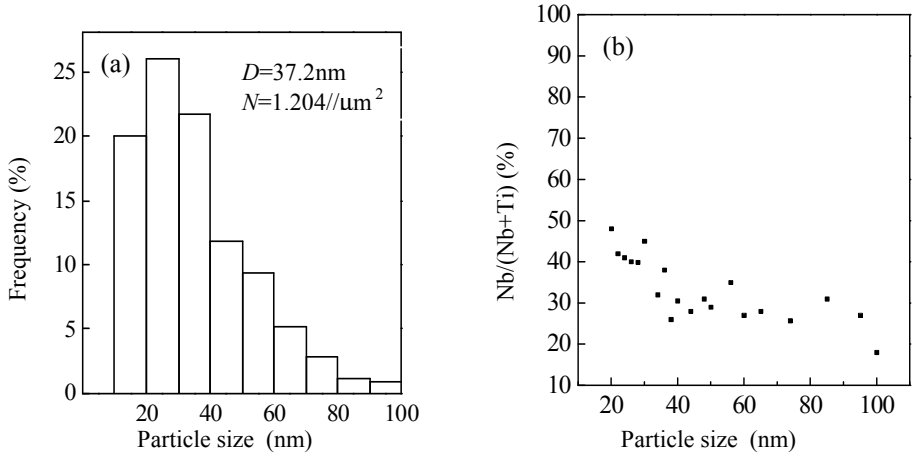

Fig. 5 Particle size distribution (a) composition distribution (b) and after weld thermal cycle with a $t_{8/5}$ of 60s

Fig. 4 shows particle size and composition distribution after weld thermal cycle with $t_{8/5}$=16s. After cooling down from 1350°C at a $t_{8/5}$ of 16s, the mean particle size increases and the particle number per unit area decreases, see Fig. 4 a and Fig. 3b, suggesting that dissolution still occurs during cooling and no homogenous reprecipitation occurs. The slight increase in Nb weight fraction after cooling down (see Fig. 4b and Fig.3c) results from the heterogeneous reprecipitation of Nb-rich particles on the survived particles.

Fig. 5 shows particle size and composition distribution after weld thermal cycle with $t_{8/5}$=60s. With increasing the $t_{8/5}$ from 16s to 60s, the particle number per unit area decreases and the average particle size increases (see Fig.5a and 4a), while the particle composition changes little (see Fig.5b and 4b). It is also noted that the small particle less than 10nm complete disappear through dissolution after weld thermal cycle with $t_{8/5}$=60s, see Fig. 5a .This confirms that dissolution still occurs in the high-temperature stage of cooling.

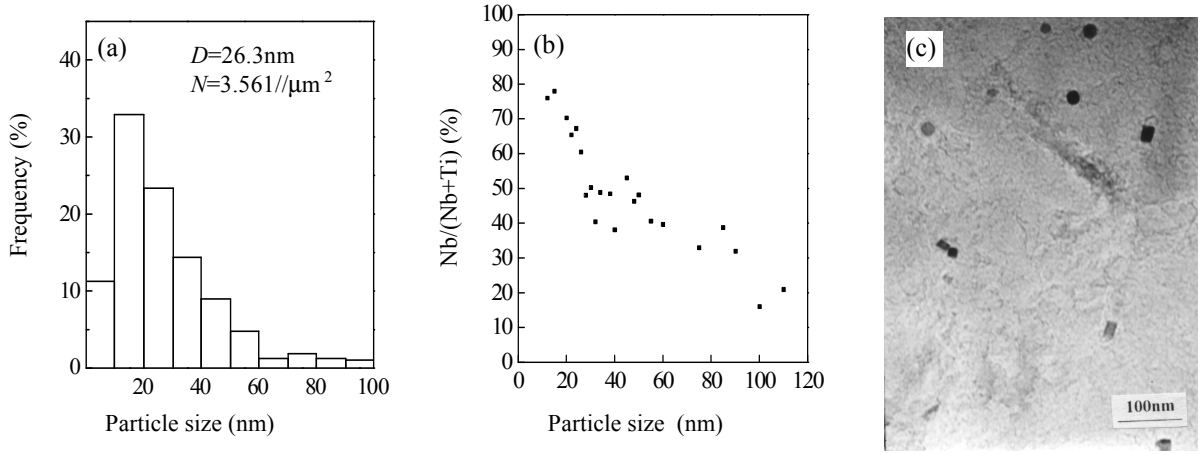

Fig. 6 Particle size distribution (a), composition distribution (b) and morphology after weld thermal cycle with a $t_{8/5}$ of 120s

With the $t_{8/5}$ increasing from 60s to 120s, the particle number per unit area increases, the mean particle size decreases unexpectedly (see Fig.6a and 5a) . It can also be noted that after cooling down from 1350°C at a $t_{8/5}$ of 120s, the mean particle size decreases and the particle number per unit area increases, see Fig. 6a and Fig. 3b; the Nb weight fraction increases and ranges from 0.18 to 0.80. These all suggest that not only heterogenous but also homogenous reprecipitation of Nb-rich partials occur when cooling at a $t_{8/5}$ of 120s. The homogenously reprecipitated particles have a spherical shape, see Fig 6c.

Conclusions

All the particles in the Ti-Nb microalloyed steel contains Nb and Ti, and the Nb weight fraction of analyzed particles ranged from 0.22 to 0.85. The large particles greater than 50nm tend to be rich in Ti (Nb/(Nb+Ti) <0.3), and large particles greater than 50nm tend to be rich in Ti (Nb/(Nb+Ti) <0.3). During the heating stage of the weld thermal cycle, the small particles which were rich in Nb disappeared through complete dissolution and the large particles survived the weld thermal cycle with Nb weight fraction decreased. With a high cooling rate ($t_{8/5}$ no greater than 60s), only heterogeneous re-precipitation occurred during cooling. With a low cooling rate ($t_{8/5}$ = 120s), homogenous re-precipitation also occurred, producing a large number of small Nb-rich particles during cooling.

Keywords: Aluminum alloys, Semi-solid, Low-pressure die casting (LPDC), Wheel, Casting defect

Abstract. Technology and defect in the low-pressure semi-solid die casting of aluminum wheel hub under different process has been studied. The simulation software ADSTEFAN 2012 is used to analyze the solidification in different die temperature. Stereomicroscope, digital camera and optical microscope (OM) are used to study defect in the casting. The result shows that the low slurry temperature (606℃) will result in higher viscosity, and the low preheated die temperature will increase the cooling rate so that shrinkage is formed in the isolate solidification area. In the technology of casting wheels, the optimum temperature of the slurry is 614℃, preheated temperature of die is 400℃.

Introduction

With the increasing attention on the environmental consequences of the burning of fossil fuels and the expected increase in the oil price, there is a growing interest in the automobile lightweight. The lightweight of automotive can be effectively achieved by using aluminum wheels [1-2].Semi-solid metal (SSM) forming has been recognized as a technique offering several potential advantages over casting and solid state forming, such as producing aluminum wheels. On one hand, contrasting with casting processes, an enhanced die life, lower shrinkage and a reduction in macroscopic and microscopic porosities are gained through SSM. On the other hand, the lower forming pressure and higher deformation homogeneity are some advantages of the SSM over traditional solid state forming procedures such as rolling and extrusion [3-6]. Generally, the main technology for casting aluminum alloy wheels is the low-pressure die casting (LPDC), which guarantees to obtain a good compromise between high mechanical properties, high production, cost-effectiveness and design demand. In the process of LPDC, filling and solidification are under a pressure which uses compressed air. Due to the fluidity of slurry will be hindered by the increased viscosity in semi-solid condition, the pressure of low-pressure semi-solid die casting is higher than LPDC [7].In order to aid the optimizing technology of filling system, computer simulation technique is introduced to predict forming process and to reduce defect during trial manufacture of automotive wheels by using low-pressure semi-solid die casting process [8-9].

Experimental Procedure

Materials and Procedures. Commercial aluminum A356 alloy (Al, 7.48 wt.% Si, 0.384 wt.% Mg, 0.132 wt.% Ti, 0.148 wt.% Fe, 0.02 wt.% Cu, 0.0067 wt.% Mn) was used. The alloy liquidus and solidus temperatures are 615℃ and 555℃, respectively [10].

Firstly, A356 alloy was melted in an electric-induction furnace setup at 720±5℃.The melt was refined with HGJ-1 and modified with HGSrB. AlTi5B1 rod type grain refiner was also added to the molten metal. Secondly, the molten metal is transferred to a crucible for low-pressure semi-solid die casting of aluminum alloy wheels. Then, the preheated die is assembled on the forming equipment. Thirdly, open the electromagnetic stirring when the temperature of molten aluminum has been decreased to semi-solid state. When slurry reaches the casting temperature, switch on the pressurized air valve. Open the die and remove the wheels after the process of filling and pressure maintaining.

Three wheels are obtained after casting. Wheel-1 is cast at 606℃ and die is preheated to 500℃, Wheel-2 is cast at 614℃ and die is preheated to 400 ℃, Wheel-3 is cast at 614℃ and die is preheated to 300℃.

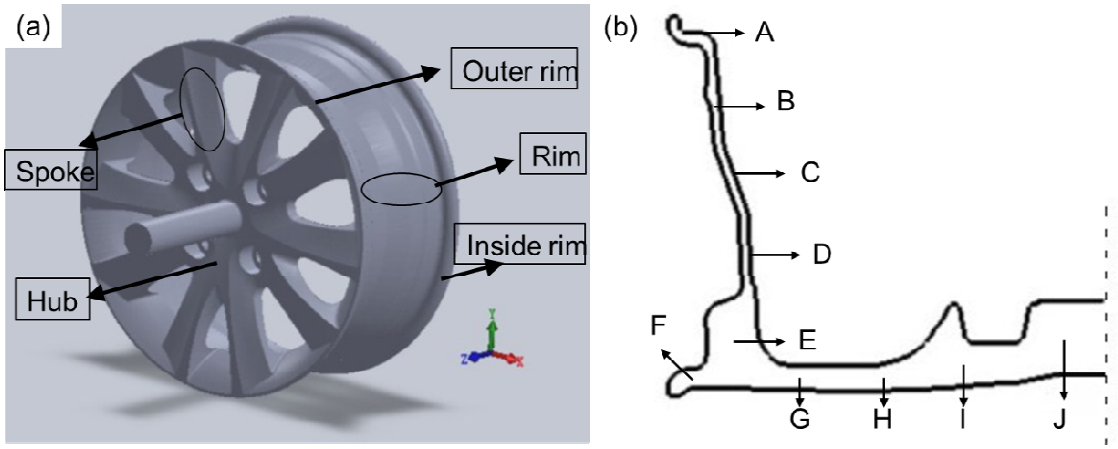

Fig. 1 (a) 3D models of automotive wheel hub, (b) wheels' section number along the XZ plane.

Casting Simulation. The ADSTEFAN2012 software which is based on the finite element method (FEM) published by Hitachi was used for study the solidification process of low-pressure semi-solid die casting. Numerical simulating parameters is that casting temperature at 614℃ and die heated temperature at 300℃and 500℃.

Analysis of Defect and Microstructure. Defect in the specimen drawn from the cross-section of spoke and rim (the position of B, C, D, G, H, I in Fig. 1(b)) region of the wheels (Fig. 1(a)) were studied with stereomicroscope and digital camera. A ruler is used as a measure of the proportion of each scale 1mm. In order to observing the section, three wheels were cut along the XZ plane in rim and XY plane in spoke (Fig. 1(a)). The microstructure and defect of wheels were evaluated by OM, which the metallographic samples come from the position A to J in the wheels.

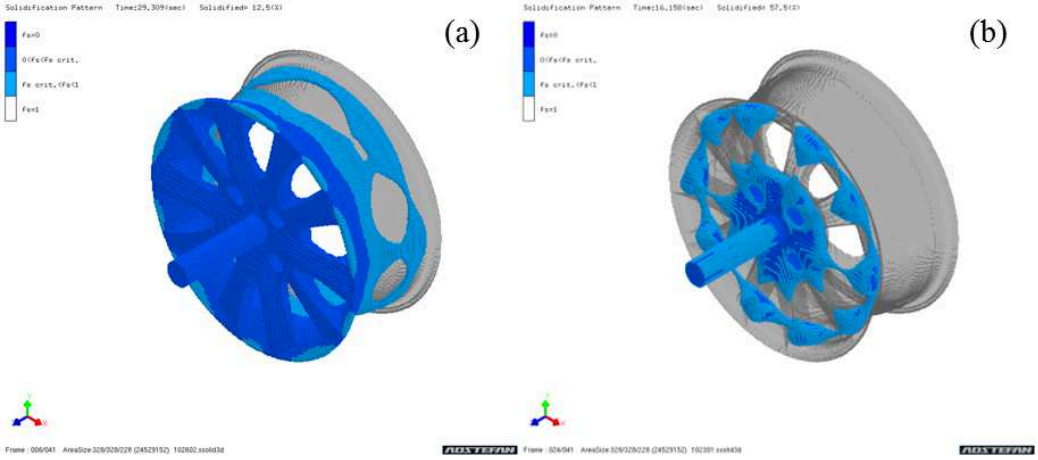

Fig. 2 Simulation results of wheel forming at filling temperature 614℃, blue represent liquid and gray is solid, (a) die preheating temperature 500℃, fs = 12.5% (b) die preheating temperature 300℃, fs = 57.5%

Results and Discussion

Simulation Results. It is easy to find shrinkage and pore at rim and spoke because of rim is thin and large, while spoke is thick and narrow. Therefore, the results of simulation select the solid-phase fraction (fs) of 12.5% to reveal the rim in Fig. 2(a), and fs of 57.5% to reveal the spoke in Fig. 2(b). Isolated solidification can be found in rim and spoke, this is called non-directional solidification. The existing of non-directional solidification result in mass shrinkage and cold shut. The purpose of this study is to decrease the extent of non-directional solidification, so as to reduce the defect.

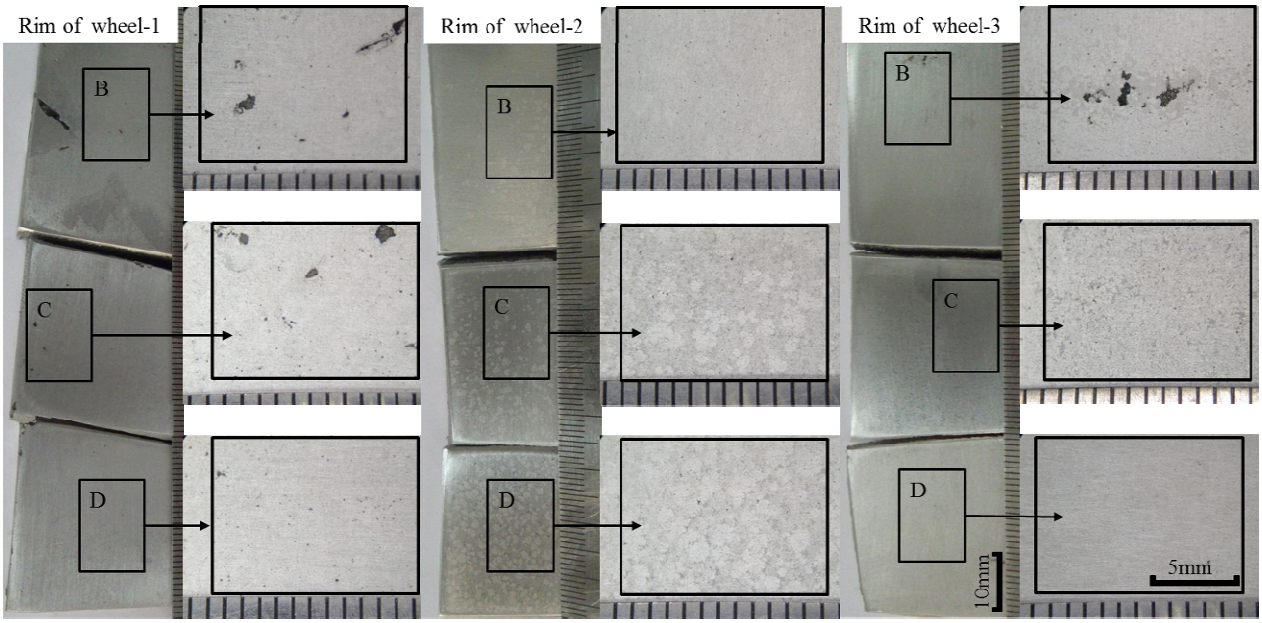

Fig. 3 Macroscopic defect of rim in wheel-1, 2, 3

Solidification Defect in Rim. Three wheels' rim is divided into three regions, respectively, B, C and D (Fig. 1(b)), and macroscopic defect situation is shown in figure 3. As shown in figure 3, there is obvious difference among the wheel-1, 2 and 3, wheel-1 has a maximum of defects, wheel-2 is fewer defects, and wheel-3 is between the two. And the macroscopic figures also show that there is much defect in the direction close to the inside rim (position B), and less defect near to the outer rim (position D), which is corresponding to simulation result (Fig. 2(a)). Solidification that start from position A and C and end with position B makes position B have more defect, on the other hand, position D has a directional solidification started from position D to G makes position D have less defect (Fig. 1(b)). Above all, wheel-1 with too much defect is because of a low slurry temperature (606℃), which results higher alloy viscosity. A low die temperature (300℃) of wheel-3 increases the cooling rate so that shrinkage is formed in the isolate solidification area.

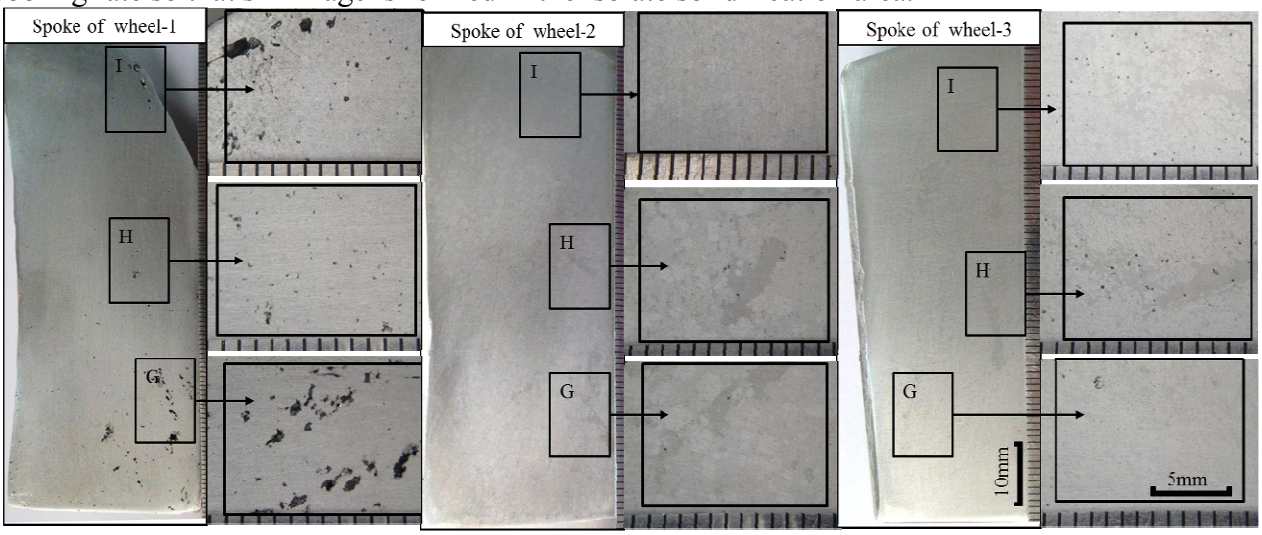

Fig. 4 Macroscopic defect of spoke in wheel-1, 2, 3

Solidification Defect in Spoke. Three wheels' spoke is divided into three regions, respectively, G, H and I (Fig. 1(b)), and macroscopic defect situation is shown in Fig. 4. It is clear to know in wheel-1 that the defect is mainly located in position G and I. In wheel-2 and wheel-3, defect is mainly loceted in position H. A non-directional solidification which start from position H and F and end with position G and J makes G and J become the final solidification areas which can generate defect easily. The defect area is moved from G to H with the die temperature declined from 500℃ (wheel-1) to

300℃ (wheel-3). The die temperature of wheel-3 is 300℃, which results in the fact that the final solidification region can not obtain continuous. Wheel-2 has fewer defect in the three wheels, and it is significant to continue research.

Microstructural Investigations. Wheel-2 shows the minimal defect combine with previous analysis. The microstructure of wheel-2 in different position are very different as illustrated in Fig. 5, where the white is primary α-Al, gray is eutectic silicon. As can be seen from Fig. 5, the direction of the wheel filling is from hub to inside rim (from position J to A), and solidified direction is the opposite order (from position A to J).

The first solidified position of inside rim and rim has a smaller grain size (Fig. 5 A, B, C), but there still exists little dendrites, which is due to higher cooling rate. As the solidification progresses, primary α-Al start to transfer from dendrites to rosette-like because of heat dissipation slows down (Fig. 5 D, E, F). The large and round is shrinkage, small and long is porosity in the gray area of eutectic silicon, which is consistent with previous analysis (Fig. 5 D, G).

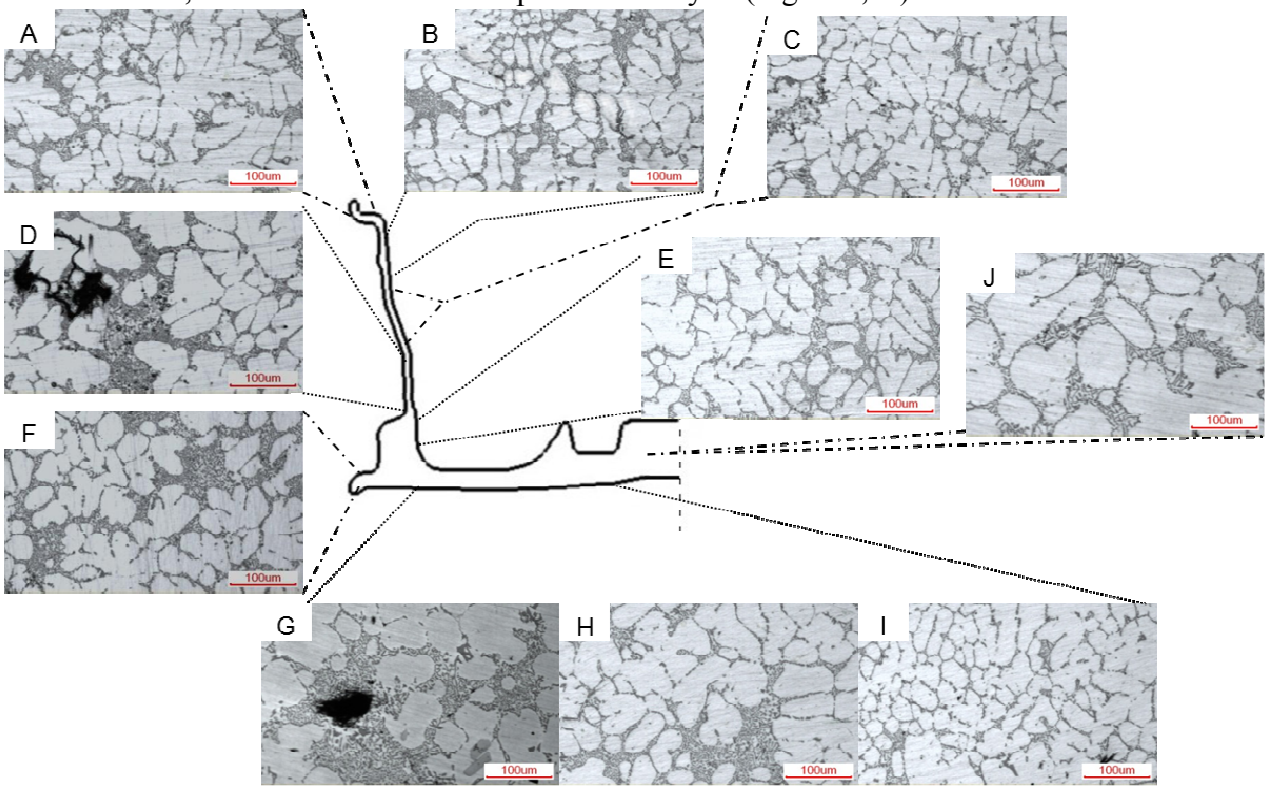

Fig. 5 Microstructure of wheel-2 located in different positions

It can be observed that primary α-Al grains start to become spherical and large slowly in the positions G, H, I, J of Fig. 5). But the grain size has become larger than rim and inside rim because of spoke and hub is massive and thermal dissipation is slow. Therefore, to prevent grain growth need to consider the factor of die design, cooling and filling process.

Summary

The technology and defect of low-pressure semi-solid die casting aluminum wheels are studied. From the simulation results, defect was predicted during the forming process because of the non-directional solidification often occurs at rim and spoken. Wheel-1 with too much defect is because of the slurry temperature is low (606℃). For another, a low die preheated temperature (300℃) will increase the cooling rate so that shrinkage is formed in the isolate solidification area. The factor of casting wheels is die structure, cooling and filling process. The results showed that optimum temperature of the slurry is 614℃, preheated temperature of die is 400℃ to decrease the casting defect.

Influence of Heat-treatment on Properties, Microstructure and Corrosion Resistant of Zirconium Sheet

DANG Peng [a], ZHANG Xiao Wei, WANG Yun, ZHANG Qing, LI Chang Liang

Western titanium technologies Co., Ltd, Xi'an 710201, China

[a] dpengg@aliyun.com,

Keywords: R60702; Vacuum annealing; Microstructure; Mechanical properties; Corrosion resistant.

Abstract: The influence of annealing temperature on the microstructure, mechanical properties and corrosion resistant of cold rolling zirconium sheet were studied in the manuscript. The experimental results shown that the tensile strength and yield strength of zirconium sheet were decreased and the elongationwas raised with the raising of annealing temperature from 500 ℃ to 580 ℃. The recrystallization are not happened in zirconium sheet at the annealing temperature of 500 ℃. Zirconium sheet complete recrystallized and the strength and elongation get a well match at the annealing temperature of 540℃. Zirconium sheet also complete recrystallized at the annealing temperature of 580℃ but the crystalline grain has the tendency of growing. The annealing temperature has no effect on the corrosion resistant of zirconium sheet.

Introduction

Zirconium and zirconium alloys are a kind of excellent corrosion resistance of rare metal and an important structural materials in the chemical industry. Zirconium and zirconium alloys show impressive corrosion resistance in harsh corrosive medium such as most of the organic acid, inorganic acid, strong base and a number of the molten salt. Greatly improve the life and reliability of the chemical equipment. In recent years, zirconium and zirconium alloys increasingly widely applied in civil chemical equipment manufacturing field, such as heat exchanger, scrubbing tower, reactor, pump and corrosive medium pipeline and so on[1-4].

However, there are some disadvantage of R60702 zirconium sheet such as instability of mechanical performance, and inconformity of corrosion resisitance, which will limited its application. Thus, the influence of annealing temperature on the microstructure, mechanical properties and corrosion resistant of cold rolling zirconium sheet were studied in the manuscript. The better heat treatment regime is determined and provide a reference for the industrial production of zirconium sheet.

Materials and Methods

The R60702 slab size is 100×1000×1200mm in this experiment. The slab chemical component as shown in table 1. The slab was heated to 650~750℃, lasting 2~2.5 h, and then its thickness was decreased to 30 mm by the first hot rolling. Subsequently, the second heating temperature was 600~700℃, holding 40~50min, and the thickness was reduced to 4.5 mm by the second hot rolling. Finally, the treated slab was dealed with cold rollding, and its thickness was changed to 3mm. After stress relief annealing and surface treatment. The zirconium sheet was disposed by vacuum annealing treatment using three different heat treatment:

Sample1: 500℃, 3h, furnace cooling;

Sample2: 540℃, 3h, furnace cooling;

Sample3: 580℃, 3h, furnace cooling.

The samples were processed 3×20×30mm which was deal with at different heat treatment. Samples successively were burnished with 200 to 800 mesh water sand paper, then were degreased with acetone, then were chemical polished in HF, HNO3 and water volume is 1:3:9 6 chemical

polishing solution, and then were rinsed with water more than 3 times, the last were rinsed with deionized water. The corrosion test were carried out after the samples drying. the samples were put in boiling 70% sulfuric acid solution, for 72 h. The operational approach carried standard GB/T4334-2008, process B. The sample weight before and after corrosion are measured using high precision electronic balance (0.0001 g). Zirconium sheet room temperature mechanical properties are tested by computer control electro-hydraulic servo universal testing machine, Zirconium plate microstructure observe by around OLYMPUS PMG3 metallographic microscope.

Table 1. Chemical compositions of slab

Furnace No.	Mass fraction/%						
	bases		impurities（≤）				
R60702	Zr+Hf	Hf	Fe+Cr	C	N	H	O
1	99.4	2	0.038	0.02	0.008	0.001	0.15
ASTM B551	≥99.2	≤4.5	0.2	0.05	0.025	0.005	0.16

Experimental Results and Analysis

The influence of annealing temperature on the mechanical properties

The room temperature mechanical of zirconium sheet properties under different annealing temperature were shown in table 2. The results shown that the tensile strength and yield strength of zirconium sheet were decreased and the elongation was raised with the raising of annealing temperature from 500 ℃ to 580 ℃. This can be explained by that the atom can be obtained more enough activity with a higher annealing temperature in the same annealing time, which make the density of point defect and dialocation decline and the internal stress gradual eliminate. The tensile strength and yield strength of zirconium sheet were decreased slightly, but the elongation has a little increased at the annealing temperature of 500 ℃. However, because the sheet was at recovery stage, and its internal stress was taken away partly at this condition, the sheet also had a higher strength and lower elongation. When the annealing temperature was raised to 540 ℃, the tensile strength and yield strength of zirconium sheet were decreased signally, while the elongation has a complete crosscurrent. At this moment, the internal stress of sample was eliminated completely, and the strength was matched with its elongation well. When the annealing temperature was 580 ℃, the strength of zirconium sheet went on declining, but the elongation only had a little change.

Table 2. Room-temperature mechanical properties of zirconium sheet annealed at various temperature

Temperature /℃	Direction	σb/MPa	σ0.2/MPa	A/%
Cold-rolled state	C	587	510	15
Cold-rolled state	L	590	517	14
500	C	565	480	17
500	L	575	505	16
540	C	467	380	28
540	L	470	372	30
580	C	420	330	27
580	L	435	340	31

C: Cross; L: Longation.

The influence of annealing temperature on the microstructure

Figure 1 was given the microstructure of zirconium sheet annealed at different temperature. From figure 1(a) and (b), it can be see that the sample does not recrystallization at the annealing temperature of 500 ℃, and both the across organization and vertical organization were processing organization. When the annealing temperature raised from 500 ℃ to 540℃, the perfect recrystallization was grown on zirconium sheet. From figure 1(c) and 1(d), it can be obtained that the grain grown up as novel and orthoscopic equiaxed grain perfectly, and the average size of grain was about 10μm. It can be

explained by that the transmutative metal transformed to a stable state spontaneously with a higher annealing temperature, deu to a higher activity. And then recrystallization core is generated by the driving of deformation energy, because that the grain boundary or subboundary are combined together. The recrystallization core is growing bigger and bigger by the driver. Until primary deformed microstructure disappear completely, the microstructure after recrystallized process present equiaxed grain, according to a lower interfacial energy. The strength of recrystallized zirconium sheet was decreased significantly, on the contrary, its plasticity was increase rapidly, which is in accordance with the teast result of mechanical property. When the annealing temperture added to 580℃, the higher temperature resulted in that the average diameter of recrystallized grain was raised up to 20μm,which can be seen clearly in figure 1(e) and (f). In this situation, the reasons of the grain growth phenomenon were that large grain swallowed small grain and the total system free energy declined after grain boundary migration.

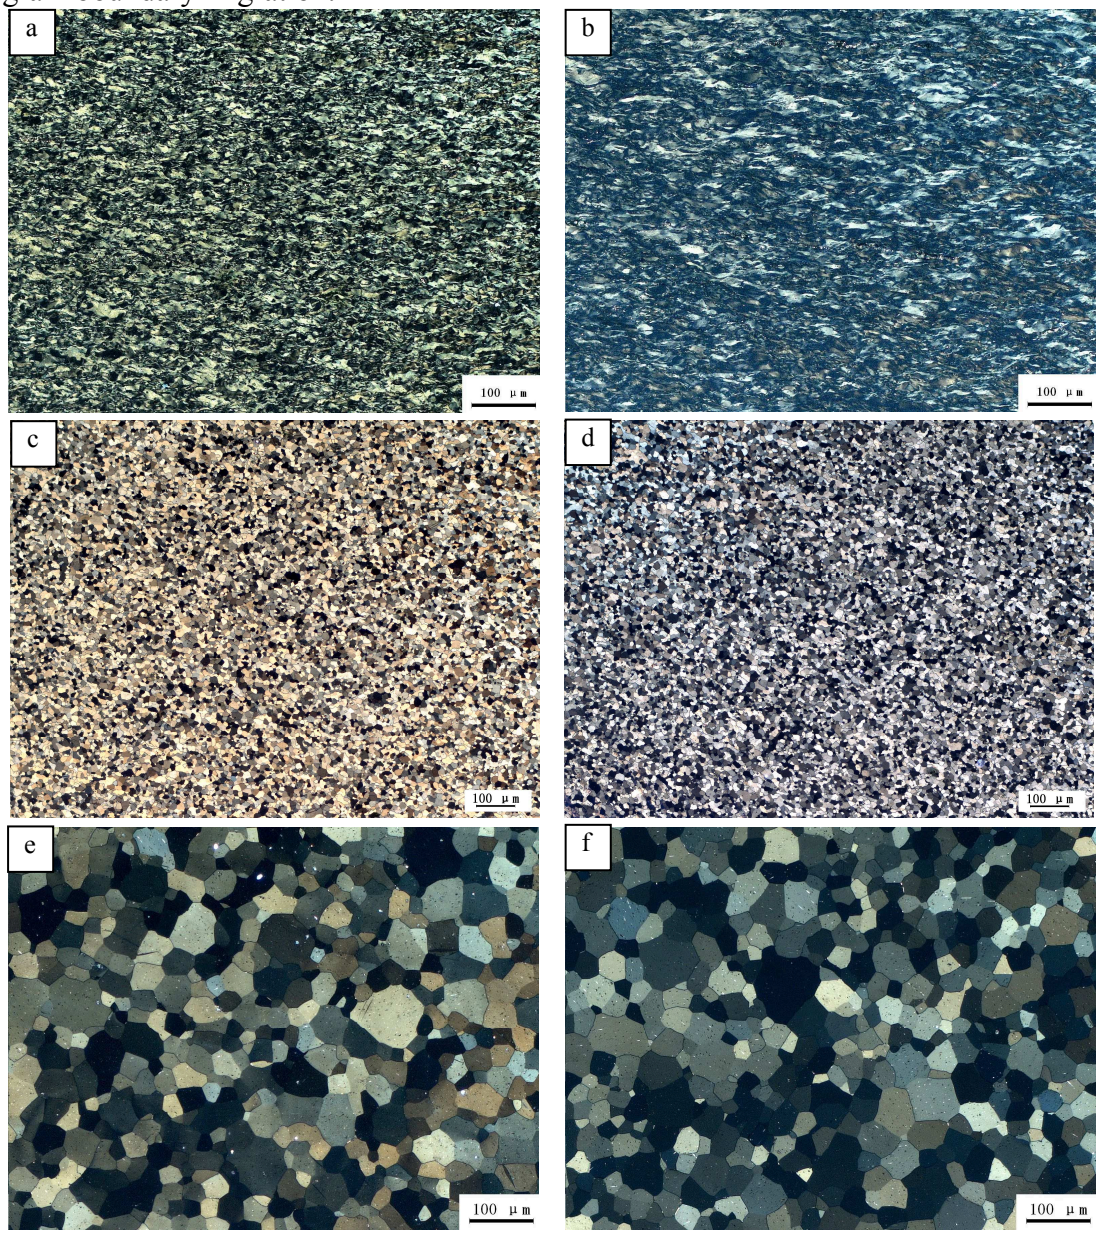

Figure 1. Microstructure of zirconium sheet annealed at various temperature
a: sample1，C，b: sample1，L，c: sample2，C
d: sample2，L，e: sample3，C，f: sample3，L

The corrosion rate of zirconium sheets annealed with different temperatures were listed in table 3. The data in table 3 shown that the corrosion rate of samples changed from 0.19 mm/year to 0.22

mm/year, which is consistent with report [5,6]. This can be explained that the superficial zirconium was oxidized as ZrO_2 in air, which because that zirconium is a reactive metal as many refractory metals. ZrO_2 film is a inert film, which hardly has chemical reaction with O or N in air. Thus zirconium had a perfectly stability. Additionally, ZrO_2 film also can be generated in strong deoxidizing medium. Figure 2 was given to indicate that the corrosion velocity of zirconium R60702 in sulfuric acid media. From this figure, it can be obtained that the zirconium can retain a low corrosion velocity in less than 70% of sulfuric acid solution, and then its corrosion velocity increased with a higher concentration of sulfuric acid solution. When the concentration of sulfuric acid solution was more than 80%, the corrosion velocity is large. The reason was that zirconium sheet was oxidized as ZrS in more than 80% sulfuric acid solution. Thus, it can be said that the corrosion resistance of zirconium closely related to the dense passive film on the surface of zirconium sheet, but not internal microstructure.

Table 3. The corrosion rate of zirconium sheets annealed at various temperature

Temperature /℃	corrosion rate/year
500	0.19mm
540	0.21mm
580	0.22mm

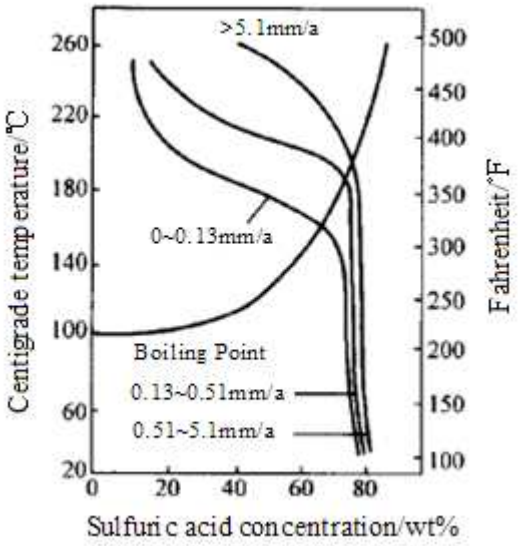

Figure 2. The corrosion rate of zirconium R60702 in sulfuric acid

Summary

The relationship of annealing temperature and the microstructure, mechanical properties and corrosion resistant of cold rolling zirconium sheet were investigated in the manuscript. From the experiment result, it can be come to the conclusion that the tensile strength and yield strength were reduced when the annealing temperature raised from 500 ℃ to 580℃, but elongation was increased. The metallograph shown that recrystallization was not appeared at the annealing temperature of 500 ℃. However, the perfect recrystallization was obtained at 540 ℃, meanwhile, the strength and plasticity cooperated very well. When the annealing temperature was up to 580 ℃, the recrystallization was also acquired, but the difference is that the grain was grown up. Lastly, corrosion experiment indicated that the annealing temperature had no effect on corrosion resistance of zirconium.

Abstract: The objective of this paper is to determine the optimum values of drilling parameters of carbon fibre reinforced carbon (CFRC) composite material with the help of an experimental investigation, which includes the application of unique Grey theory method. The growing application of CFRC composites, which are popularly known as 'carbon-carbon' composites in Aerospace, Automobile, Defence and other advanced industries has prompted research studies to develop drilling technology of these special materials. The present work demonstrates the optimization process of multiple responses.The optimum values of drilling characteristics of these composites are calculated by the application of Taguchi method in combination with Grey Relational Analysis technique. The drilling experiments were carried with a High speed steel tool on a plate of carbon-carbon composite material on a CNC Drilling vertical Machining centre.

Introduction

Drilling is probably the most frequently used metal cutting process operation and it is one of the major complicated machining processes. This process further becomes more complicated, when the work piece is a composite material. But much attention was not given on the drilling process of the most advanced and promising engineering material called 'carbon fiber reinforced carbon (CFRC)' composite. The use of CFRC composites in Aerospace, Automobile, Defence, Bio and other related industries has grown recently, due to their low weight and high strength properties. Drilling of Carbon Fibre Reinforced Carbon composites may generate several kinds of damage, which can lead to the degradation of quality of holes. Hence care should be taken in selecting the parameters of drilling process. Hence an experimental investigation of drilling of Carbon-Carbon composites has been considered for study.

CFRC composites-Fabrication and uses

CFRC or C-C composites are the materials, in which Carbon/Graphite fibres are reinforced in a Carbon Matrix. The Carbon fibre preform, which is woven, is impregnated under heat and pressure with pitch. This is followed by pyrolysis of the pitch to obtain a carbonaceous matrix. .This cycle may be repeated to obtain the desired densification. This is also obtained by chemical vapour deposition method from a gaseous phase [1]. CFRC seems to be a promising material for use in orthopedic surgery due to its good biocompatibility and low stiffness. The replacement of knee and hip joints with metallic prosthetic devices has provided mobility to many elderly patients suffering from bone diseases. Heart valves have been produced with isotropic pyrolitic carbon and they have been implanted in more than two lakh patients [2].Most notable applications of this special material are Heat shields for re entry vehicles, hot pressing dies, nozzles, and nose cones of intercontinental ballistic missiles and leading edges of the space shuttles. Carbon/Carbon brakes are used in subsonic aircrafts, supersonic aircrafts and racing cars. Tooling, Racing Helmets, Race car seats, sports equipment etc., are built entirely from carbon-carbon composites. Agni missile, a reentry structure has used this advanced material for its production. CVRDE has developed high performance Carbon fibre reinforced carbon Brake discs for Main Brake assembly of MBT Arjun [3.4,5].

Taguchi method and Grey theory method

Design of Experiment is a powerful statistical tool suggested by Mr. Taguchi is used to design and conduct the experiments with minimum resources. Orthogonal Array is a statistical method of defining parameters that convert test areas into factors and levels. In this work, an L_{27} orthogonal array table was chosen for the experiments based on Taguchi's quality design technique as shown in fig.1 [6].

Fig. 1 Orthogonal array (l_{27})

Grey theory, which was introduced by Mr. Deng, provides an efficient solution to uncertain and multi-input problems. By this method, the experimental results are first normalized and then the grey relational coefficients are calculated from data. Then, the grey relational grade was computed by averaging the grey relational coefficients corresponding to each response parameter. The overall evaluation of the multiple responses is based on the grey relational grade. Optimization of a factor is the level with the highest grey relational grade [7].

Experimental Investigation

Drill bit point Angle, Spindle speed and Feed rate were chosen as the controlling drilling parameters and each parameter was designed to have three levels, denoted by 1, 2, and 3 as shown in Table 1.

TABLE 1: EXPERIMENTAL PROCESS PARAMETERS AND THEIR LEVELS

Drilling Parameters	Symbol	Unit	Level (1)	Level (2)	Level (3)
Point Angle	A	degree	100	118	135
Spindle Speed	N	r.p.m	1000	2000	3000
Feed Rate	F	mm/rev	100	300	500

The experiments were carried out on a computer numerical control Vertical Machining centre (VMC100). A Tin coated solid carbide drill bit of 10mm diameter is used for drilling of carbon-carbon composite material plate. The experimental setup is shown in Fig.2.

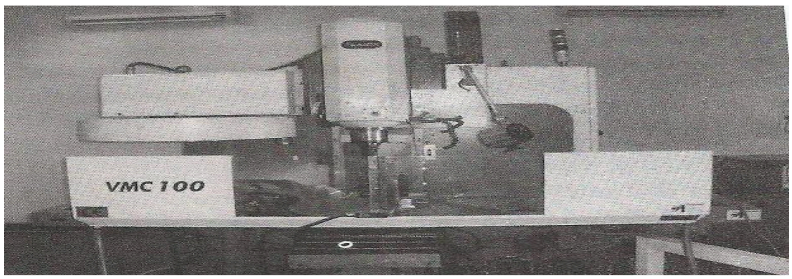

Fig.2 CNC vertical machining centre

The drilling process performance is evaluated by five following response parameters.

Thrust Force

It is the axial force required to drill the work material and is measured in Newtons. The values are obtained by observing through Kistler make piezoelectric dynamometer . Data acquisition and analysis software, Dynoware is used to plot the force signals with respect to time. The typical plot observed in experimental study is shown in Fig.3.

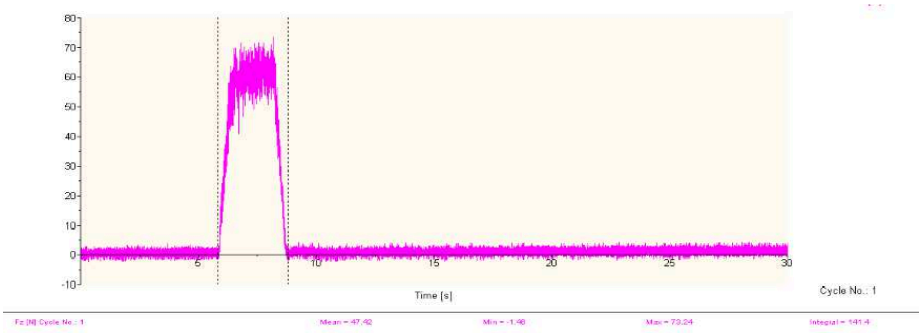

Fig.3 A typical thrust force observed from Kistler Dynamometer

Torque

It is the twisting moment required to drill the work piece and is measured in N-m. The Torque values are obtained by observing through Kistler piezoelectric dynamometer by means of sensors. Dynoware is used to plot the torque signals with respect to time. The typical plot observed in experimental study is shown in Fig. 4.

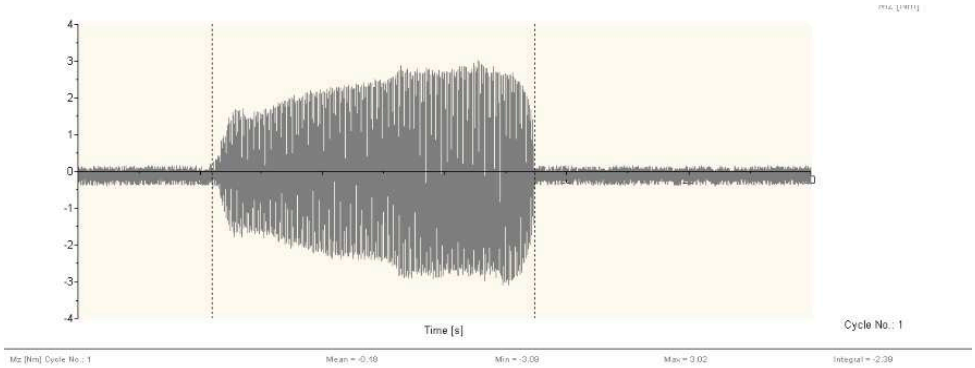

Fig.4 A typical torque observed from Kistler Dynamometer

Surface Roughness {R_a}

It is the roughness of the walls of the drilled hole and is measured in microns. It is measured by using Surface Roughness Tester**.** The setup is shown in fig.5**.** The arithmetic mean average roughness (R_a) is used to indicate the roughness of a drilled surface.

Delamination Factor {D_f}

It is the degree of Delamination and Delamination is a mode of failure in composite materials. It is the separation of layers in a laminate. The most important phases during drilling composite laminates are close to the entry and exit where extensive damage in terms of delamination occur due to peel-up and push-out effects respectively [8].The drilled holes are photographed by using a digital camera and it is measured with the help of Corel Draw image software. The values of diameters of drilled holes are magnified by 5 times and the delamination factor is calculated by using the ratio D_{max}/D.

Fig.5 Surface roughness tester

The experimental values of all five response parameters are given in Table.2.

TABLE 2: EXPERIMENTAL VALUES OF T.F, TORQUE, RA AND DELAMINATION FACTORS (ENTRY &EXIT)

Data Deprocessing

Generally the normalized value of the data is known as comparable sequence. The range and unit in one data sequence may differ from others, hence normalization is necessary. It is also necessary when the sequence scatter range is too large, or when the directions of the target in the sequences are different.

The normalized value of "higher-the-better" characteristic and it is expressed as,

$$x_i^*(k) = \frac{x_i^0(k) - \min x_i^0(k)}{\max x_i^0(k) - \min x_i^0(k)} \quad (1)$$

The normalized value of "lower-the-better characteristic is expressed as,

$$x_i^*(k) = \frac{max\, x_i^0(k) - x_i^0(k)}{\max x_i^0(k) - \min x_i^0(k)} \quad (2)$$

If the characteristic is "nominal-the-best", then the normalized value is expressed as,

$$x_i^*(k) = 1 - \frac{|x_i^0(k) - x^0|}{\mathrm{Max}\, x_i^0(k) - x^0} \quad (3)$$

Where i=1… m; k=1… n. m is the number of experimental data items and n is the number of parameters. $x_i^0(k)$ is the original sequence, $x_i^*(k)$ is the sequence after the normalization, $max\, x_i^0(k)$ is the largest value and $\min x_i^0(k)$ is the smallest value of $x_i^0(k)$ and x^0 is the desired target value [9].The normalized values of the response parameters are tabulated in Table 3.

Determination of Grey Relational coefficients and Grades

The GRC (grey relational coefficient) value is calculated after the calculation of normalized values. The GRC expresses the relationship between the ideal and the actual normalized experimental results. The Grey Relational Coefficient, $G_{ij\ is}$ expressed as,

$$G_{ij} = \{\Delta_{min} + \zeta\Delta_{max}\} / \{|x_i^0 - x_{ij}| + \zeta\Delta_{max}\} \quad (4)$$

Where x_i^o is the ideal normalized results for the i^{th} performance characteristic and ζ is the distinguishing coefficient, which is defined in the range $0 \leq \zeta \geq 1$. But for practical purposes, ζ is taken as 0.5.

After the calculation of GRC values, the data can be reduced to a single value known as Grey Relational Grade (GRG). The GRG is calculated by the following formula by giving equal importance to the influence of various response parameters. The GRC and GRG values of all 27 trials are entered in Table.4.

$$\mathrm{GRG}\ (\alpha_j) = \frac{1}{N}\sum_{I=1}^{N} G_{ij} \quad (5)$$

The highest grey relational grade will give the optimal combination of various process parameters.i.e. 0.803775 (7th experiment).

Experimental Results Analysis by Using Response Table and Response Graphs.

The average grey relational grade for each level of all input parameters can be computed and the overall mean also calculated and entered in the Table 5.

TABLE 5. RESPONSE TABLE

DRILLING PARAMETER	SYMBOL	GREY RELATIONAL GRADE		
		Level 1	Level 2	Level 3
Point Angle	A	**0.6467**	0.5199	0.5844
Spindle Speed	N	0.5870	0.5460	**0.6179**
Feed Rate	F	**0.6087**	0.6077	0.5345
Overall mean of Grey Relational Grade = 0.5836				

The effect of each drilling parameter can be clearly presented by means of the response graph shown in Fig 5.

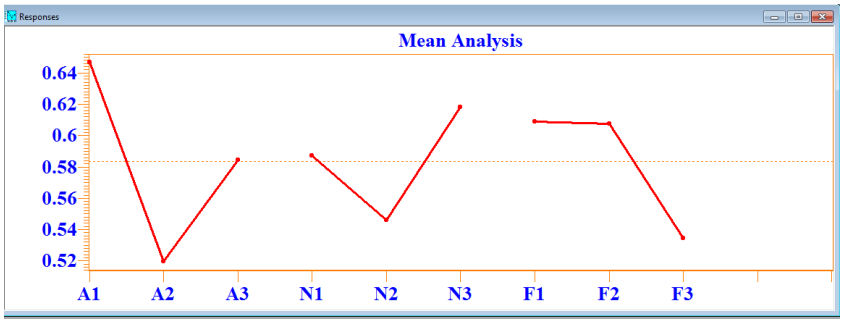

Fig.5 Response Graph

Validation Experiment

After the optimal level has been selected, the final step is to predict and verify the improvement in the response characteristics for the CFRC plate by drilling process with respect to the chosen initial parameter setting.

This validation test is important and last part of the parametric design. The expected mean grey relational grade at the optimal settings is calculated by using the following model.

$$\tilde{\alpha} = \alpha_m + \sum_{i=1}^{n} [\overline{\alpha_1} - \alpha_m] \quad (6)$$

where α is the total mean of grey relational grade, $\bar{\alpha}$ is the mean grey relational grade corresponding to the i^{th} significant factor on the j^{th} level and n is the no. of significant factors that affect the multiple response parameters.

The predicted value of GRG,

$$\tilde{\alpha} = 0.5836 + (0.6467-0.5836) + (0.6179-0.5836) + (0.6087-0.5836) = 0.7061$$

TABLE 6: RESULTS OF VALIDATION EXPERIMENT

Setting Level	Initial Drilling process Parameters	Optimal Drilling process Parameters	
		Prediction	Experiment
Response Parameters	$A_2N_3F_3$	$A_1N_3F_1$	$A_1N_3F_1$
TF [N]	63.06	-	12.18
M[N-m]	10.3	-	1.32
$R_{a[}\mu m]$	4.20	-	3.93
Entry-D_f	1.0433	-	1.0091
Exit-D_f	1.1089	-	1.0347
Grade	0.4181	0.7061	0.8037

Table 6, shows the comparison of the predicted and the actual drilling performance of the Tin coated solid carbide drill for multiple performance characteristics using their optimal cutting parameters. The confirmation experiment results at the optimal level show that Thrust Force is decreased from 63.06 N to 12.18 N, Torque is also decreased from 10.3 N-m to 1.32N-m, Surface finish has improved from 4.2 μm to 3.93 μm and delamination factor has also come down in both the cases, i.e., entry and exit of holes due to the improvement of grade by 0.3856.It is clearly evident from the results that the multiple performance characteristics in the CFRC composite material drilling process are greatly improved through this technique.

Conclusion

1. The predicted results were checked with experimental results and a good agreement was found.
2. A point angle of 100^0, a feed rate of 100mm/rev and a spindle speed of 3000 rpm of 7^{th} experiment is the optimal combination to have good drilling results.
3. A combination of high speed and low values of feed rate and point angle seems to be an appropriate selection for minimizing the delamination.

Keywords: Shot coke, Microwave heating, Activated carbon

Abstract. The activated carbon was prepared from the Jing Bo shot coke using KOH as the activation agent by microwave heating. The effect of microwave radiation time, the microwave power and the ratio of activation to shot coke on the properties of the activated carbon were investigated in detail. The result showed that the optimized condition of preparation of activated carbon is as followed: the ratio of activation agent to shot coke is 3:1, the microwave power 900 W and the microwave radiation time is 40 min. In this condition, the BET surface area of the activated carbon is 2668 m^2/g; the iodine adsorption value 2281 mg/g and the benzene adsorption value 1368 mg/g.

Introduction

Activated carbon is the most widely used adsorbent because of its larger porous area which has been commonly used for adsorption separation purification in pharmaceutical, food, environmental, chemical engineering and especially in pollution control applications. The precursor of activated carbon can be coal, wood, fruit shells and coke. During upgrading, a larger amount of petroleum coke is generated as a by-product. And the amount of petroleum coke is rapidly increasing along with the worldwide supply of heavy crude oil continues to increase. Currently most of the petroleum cokes are used as aluminum industrial fuel combustion with low value and low processing depth. While as the precursor of activated carbon, petroleum coke has great advantages of low cost and high carbon content. Shot coke is a kind of petroleum coke, with spherical the shape, smooth and shiny little hole, generally only used for power generation, cement and other industrial fuels [1]. In this article, the shot coke was used to prepare the active carbons.

Microwave heating in the environment applications in recent years has caused considerable attention of researchers which has unique advantages over convention heating method due to its high energy efficiency, fast heating rate, volume and selective heating from the inside to the outside of the heating [2,3]. Most of the carbonaceous material have a high dielectric loss, and can be quickly heated in a microwave oven [4]. The above advantages provide a strong motivation to prepare the activated carbon from shot coke in trough microwave heating. This paper reports a method for the preparation of high surface area active carbon from coke by microwave radiation

using KOH as active regent. Factors affecting the adsorption properties of the products produced with microwave activation were studied as well as the BET surface area and pore volume of the activated carbon. Optimizing the microwave conditions and the KOH/Coke ratio were investigated in the article.

Experimental

Preparation of microporous activated carbons

The shot coke from Shandong Jingbo Holdings Co., Ltd was used as raw material. It was grounded and sieved to 74 μm before use. The Proximate and elemental analysis of shot coke is listed in table 1.

TABLE 1 PROXIMATE AND ELEMENTAL ANALYSIS OF SHOT COKE

Parameter	Proximate analysis (wt %)			Elemental analysis (wt %)				
	A	V	M	C	H	N	S	O[b]
Raw	0.6644	10.60	0.86	88.61	3.57	2.20	2.65	2.97

[b] by difference

Then the shot coke was placed in a drying oven for 24 h and at 120 ℃ and mixed with KOH. A 2.45 GHz microwave oven (MKG-F2-1) with 1400W nominal power output and continuously adjustable microwave power was used for activation the coke samples. The mixture was placed in a microwave tube oven which was purged with 100 cm^3/min nitrogen to provide an inert atmosphere. After activation, the activated carbon was washed with hydrochloric acid and deionized water till neutral. Then, it was dried at120 ℃in an oven for 24 h.

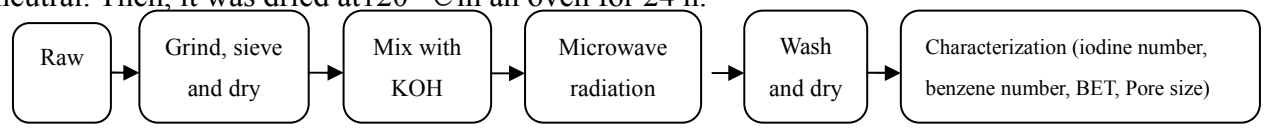

Fig.1 A schematic diagram for the microwave activation process

Characterization of microporous activated carbon

The iodine adsorption value was determined according to the standard test method GB / T 7702.7-2008. The adsorption of benzene was measured by a static Paul drying method, namely: 0.1 g of sample is placed in a desiccator containing benzene for 24 h. Based on the mass changes before and after the adsorption, benzene adsorption value of per gram of activated carbon was obtained.

The specific surface area and pore structure of activated carbon were measured using low temperature (77 K) N_2 adsorption method by a surface area analyzer (Quantachrome Instruments, Autosorb-1). The total surface areas were calculated from the BET formula, the total pore volume were measured when the relative pressure P/P0 = 0.97, and the micropore volume from the t-plot method, pore size distribution from the BJH method. The surface morphology of raw materials and activated carbon was characterized using a scanning electron microscope (Japanese production, JED-2300).

Results and discussion

Effect of microwave radiation time

According to the literature [5-7], in this paper we chose KOH as activating agent. The effect of microwave heating time was studied at a KOH/Coke ratio of 3:1. Fig.2 shows the effect of microwave radiation time on iodine and benzene adsorption properties.

As can be seen from the figure, both of the adsorption values didn't monotonically with the microwave heating time, and the iodine adsorption and benzene adsorption of the activated carbon both reached the maximum at 40 min of microwave heating. When the radiation time was lower than 40 min the adsorption of iodine increased with the increasing activation time, while after 40 min, the iodine value of activated carbon decreased. The benzene adsorption value showed the same trend with microwave heating time. Overall, the Adsorption properties of activated carbon achieved the best conditions in the heating time of 40. This may be due to that the rate of generating new hole of raw material is higher than rate of the sample being ablated, the number of holes presents upward trend, and therefore increases the adsorption performance. With the increase of the activation time, the generation rate is gradually reduced, and is less than the rate of ablation, reducing the overall numbers of the holes, so that the adsorption properties of activated carbon decreased.

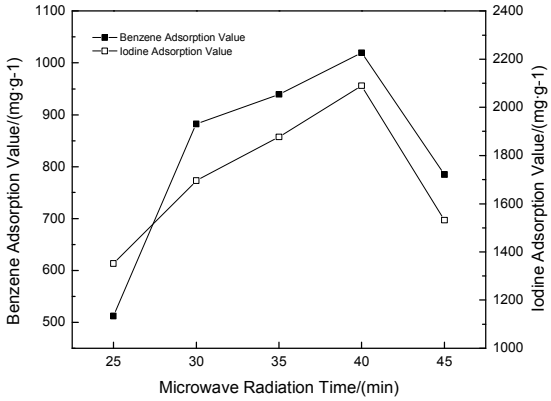

Fig.2 Effect of microwave radiation time on adsorption properties of activated carbon

TABLE 2 BET SURFACE AREA AND PORE STRUCTURE PARAMETERS OF ACS MADE BY DIFFERENT MICROWAVE RADIATION TIME

Microwave radiation time (min)	BET surface area ($m^2 \cdot g^{-1}$)	Total pore volume ($cm^3 \cdot g^{-1}$)	Pore diameter (nm)	Micropore volume (%)
25	1132.8	0.57	2.02	93.2
30	1913.4	0.99	2.08	90.0
35	1903.1	1.00	2.10	93.6
40	1960.8	0.99	2.02	92.9
45	1196.8	0.72	2.42	78.6

Table 2 presents the effect of microwave heating time on the pore structure. It can be found that the BET surface area of activated carbon and total pore volume were increased with the increase of heating time, and then decreased at 40min. This may because most of the holes that the activation produced are micropore. The rising content of microspores determined the BET surface area and total pore volume. While the activation time increasing, the rate of ablation of activated carbon increased and part of the microporous collapsed, which lead to the micropore content gradually reducing along with the BET surface area and pore volume decreased as well.

Effect of microwave power

Fig.3 presents the effect of microwave power on adsorption properties of activated carbon while the microwave heating time was 40min, the KOH/Coke ratio of 3:1.

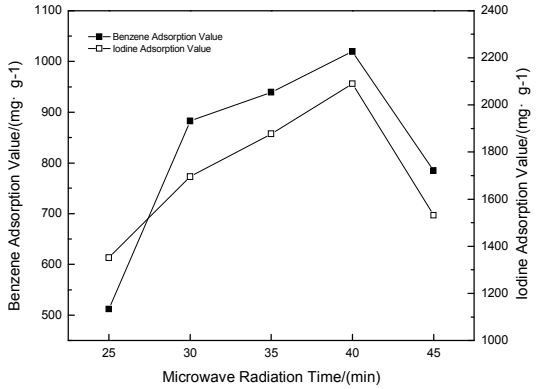

Fig.3 Effect Of Microwave Power On Adsorption Properties Of Activated Carbon

Figure 3 shows that with the increase of microwave power, benzene and iodine adsorption of activated carbon showed a decreasing trend after the first increase. When the microwave power is 900 W, adsorption got maximum properties. This is mainly due to that when the microwave power increased; the material temperature can be raised to promote the activation reaction, accelerating the hole generating speed, thereby improving the adsorption performance of activated carbon. However, higher than 900W, the power increases as well as the ablation of the material increases. The pore structure of the new generation is ablated, collapse, resulting in the decrease of the number and volume of the pores. Thus the adsorption performance of activated carbon degraded [8, 9].

TABLE 3 BET SURFACE AREA AND PORE STRUCTURE PARAMETERS OF ACS MADE BY DIFFERENT MICROWAVE POWER

Microwave power (W)	BET surface area ($m^2 \cdot g^{-1}$)	Total pore volume ($cm^3 \cdot g^{-1}$)	Pore diameter (nm)	Micropore volume (%)
600	2314.8	1.20	2.25	92.16
700	2316.8	1.13	2.10	92.61
900	2668.3	1.39	2.24	92.95
1000	1972.0	0.98	2.15	92.25
1200	1777.5	0.86	2.03	94.63

Table 3 indicated the BET surface area and pore structure parameters of ACs made by different microwave power. With the increasing power the BET area and total pore volume of the activated carbon increases. It can be seen that the increasing of power lead to a fast heating rate thus the activation behavior become obvious reflecting the pore development behavior. When the power was 900 W, the activated carbon surface area and total pore volume reached a maximum. Higher than 900 W, the sample was overreacted with pore collapsing along with the decreasing of the surface area and total pore volume.

Effect of KOH/Coke ratio

The effect of KOH/Coke ratio on the properties of the activated carbon was studied for the coke exposed to 900W microwave power for 40min.

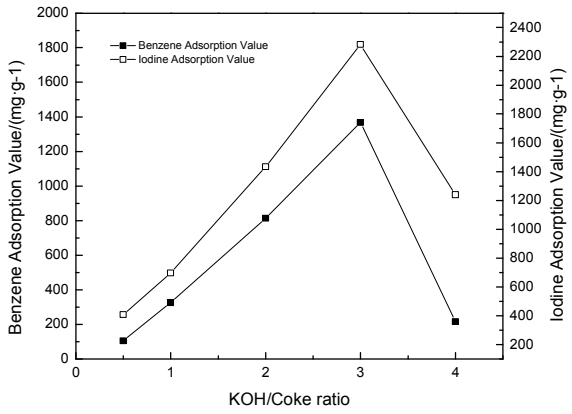

Fig.4 Effect of KOH/Coke ratio on adsorption properties of activated carbon

Fig.4 Shows the iodine and benzene adsorption value of the activated carbon at different KOH/Coke ratio. From the figure, we can see that when the KOH/Coke was 3:1, the activated carbons perform best. In the low range of ratio, the adsorption performance of activated carbon increases significantly as the ratio increased. When the agent coke ratio is higher than 3:1, the adsorption properties of activated carbon decreased. It can considered that with low ratio, the raw material was not fully activated, pore structure formation was not fully developed, so the adsorption performance of activated carbon was poor; As agents coke increases, the reaction between KOH and raw materials got developed, so the degree of porosity increased. Thus the activated carbon's adsorption property was also enhanced. When agents coke was 4:1, some micropore collapsed, resulting in decrease of absorption values.

Table 4 shows that the specific surface area of activated carbon, total pore volume and micropore rate was first increased and downward later when the ratio increased, the optimal KOH/Coke radio was 3:1. This was because when the agent coke ratio is increased, the better the mixing performance of raw material and activator is, the larger the contact area is, and therefore the activation react more fully and the micropore content is large, so the specific surface area and the total pore volume of the activated carbon rise . When the agent to achieve the best focal ratio, as the focal ratio of the agent is increased, because of the excess activating agent, the reaction is too violent and activated ablation rate increase; the new generation of pores continuously burned into collapse, resulting in reduce of micropore content. Thus the surface area and pore volume of activated carbon decreased [10, 11].

TABLE 4 BET SURFACE AREA AND PORE STRUCTURE PARAMETERS OF ACS MADE BY DIFFERENT KOH/COKE RADIO

KOH/Coke radio	BET surface area ($m^2 \cdot g^{-1}$)	Total pore volume ($cm^3 \cdot g^{-1}$)	Pore diameter (nm)	Micropore volume (%)
1:2	130.4	0.08	2.34	79.1
1:1	457.7	0.25	2.17	89.5
2:1	2146.9	1.14	2.13	92.5
3:1	2688.3	1.50	2.24	92.9
4:1	1503.9	0.81	2.16	88.8

SEM images

Figure 5 shows SEM images of samples under different power conditions. In the Figure 5 (a), we can see that in the layered structure of raw petroleum coke is more obvious, but the surface has

almost no gaps. After activation, the surface of petroleum coke is etched, showing varying degrees of crack. In particular, Figure 5 (b) and Fig 5 (c) etching is obvious, this is consistent with a high surface area activated carbon and the developed pore structure under this conditions. These cracks may extend to the very interior of the particle, although these cracks and cavities do not provide greater surface area and adsorption properties, they are able to provide the adsorbate a passage to enter microporous and mesopore of the particles. Figure 5 (d) shows surface pores is more obvious and surface smooth. This may be that in the higher power, the structural order of activated carbon improved and part of the pore collapse. This is more consistent with the aforementioned decrease in the specific surface area.

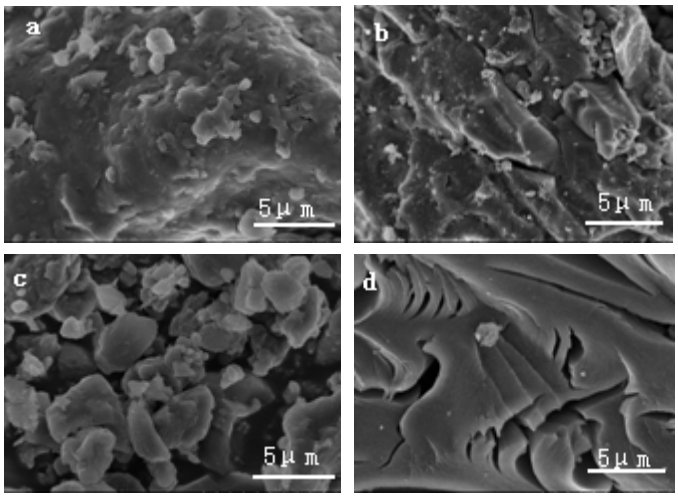

Fig.5 SEM images of different sample treated at different conditions

a .untreated; b. 800 W/40 min; c. 900 W/40 min; d. 1200 W/40 min.

Conclusions

The research determined the effect of different factors on the quality of activated carbon prepared from shot coke using microwave heating and KOH as activation agent. Based on the obtained results, the following conclusion can be made:

(1)The optimum KOH/ coke ratio and microwave power as well as microwave heating time exists due to the adsorption performance of the activated carbon. The optimum conditions of the microwave heating method for the microwave heating activation of activated carbon from shot coke are as follows: KOH as the activation agent, microwave power of 900 W and microwave heating time of 40 min, KOH/coke ratio of 3:1. Under this optimal condition, the BET area of the activated carbon reached 2668.3 $m^2 \cdot g^{-1}$with great iodine and benzene adsorption properties.

(2) Microwave-assisted activation of KOH mainly produce micropore with the microporous rates above 78% and up to 94.6%, with an average pore size distribution of about 2 nm.

Abstract: Nowadays Non-Crimp Fabrics (NCF) are of substantial use in the field of technical textiles. Due to their lightweight, multilayer set-up, NCF became to an important factor for several technology sectors, i. e. automotive, wind energy and civil engineering. In order to eliminate known drawbacks of current manufacturing technologies, to enhance mechanical properties and to increase production speed of such NCF, a novel technology is proposed. This manufacturing technique is based on the adhesive bonding of layers made of high-performance fibres. Different adhesives were investigated to check their wettability and adhesion properties in relation to the high-performance fibres made of carbon or glass. Furthermore, the interface between the adhesive and a classical matrix for fibre-reinforced plastics was examined.

Introduction

As lightweight materials for fibre-reinforced composites, Non-Crimp Fabrics (NCF) are increasingly used for applications as diverse as automotive, aerospace or civil engineering. Because of the ascending demand of technical textiles, the production process has to be revised as well as limitations of production have to be improved [1].

Issue. In a classic multiaxial warp-knitting machine, several layers of unidirectional high-performance fibres are fastened during a stich-bonding step. The reinforcement yarns are set up in the load direction of the prospective structural element. This technique induces a couple of disadvantages. Single filaments in the high-performance yarn can be damaged, which reduces the load transmission capacity [1]. In addition, the warp-knitting yarn narrows down the cross-section of the yarn and causes ‘fish-eyes’ in a layer of a closed NCF [2]. Such gaps represent a weak point for reinforced materials due to the accumulation of resin and the fact that an accurate position of load bearing fibres is no longer assured.

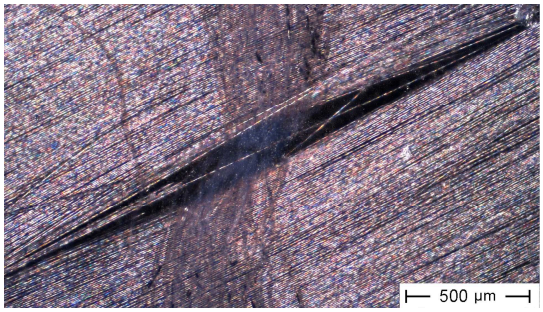

Figure 1: ‚Fish-eyes‘ in a closed NCF made of carbon

Therefore, a non-destructive joining method would be desirable that replaces the warp-knitting yarn in the NCF. The bonding with a adhesive system is proposed. Consequently, a new production technology for NCF has to be developed, which is the aim of the young researcher group SAXOMAX supported by the European Social Fund ESF.

The new process implies different key aspects which have to be clarified. For example, the adhesive system has to be suitable to the used high-performance fibre, to the process conditions and typical reinforcement matrices. Different adhesives were taken into account, i. e. hotmelts and reactive systems as cyanoacrylates. To ensure a good wettability of the binder to the yarn, the surfaces of fibres were modified by oxi-fluorination and plasma treatment. Finally, a method for adhesive application was developed that depends on the mode of action of adhesive corresponding to different chemical and physicochemical conditions.

Novel Production Technology. To a great extent, a warp-knitting unit is used to join at least two layers to an NCF with high-performance yarns made of carbon or glass. For special applications, the 'walking-needle' was invented to preserve the damaging by the stitching needle. In this case, the warp knitting unit moves in the conveying direction of the warp thread.

This work focuses on another approach which is the replacement of the warp-knitting unit by a binder application unit. Here, the adhesive is applied through the multilayer fabric in one step to fix the NCF. This method is defined by the use of a nozzle system for reactive adhesives and for hotmelts that fix a multilayer fabric in one step. To achieve the required draping properties of the fabric, smallest amounts of adhesive and statistically distributed adhesive dots in accordance with the later application are desired (Figure 2, right). These technical demands will be realized in a demonstrator by a jet valve P-jet CT (Liquidyn, Germany) and a Kuka robot KR 6- R900 which enables movements around six axes.

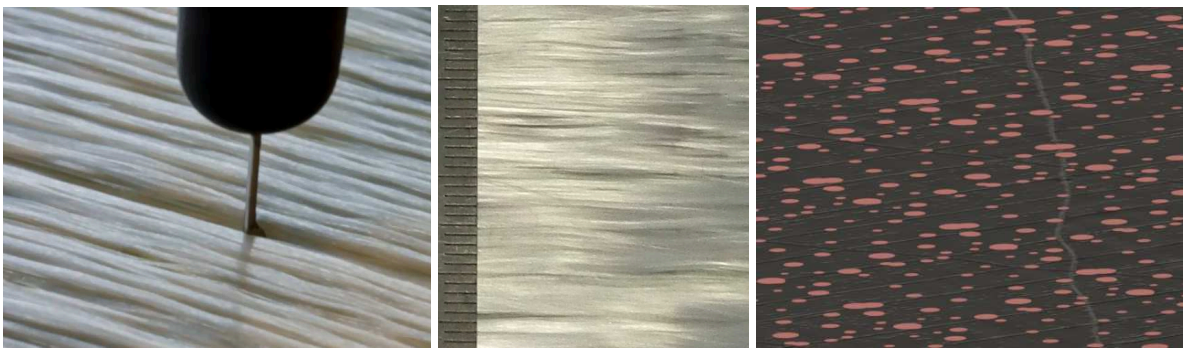

Figure 2: Left, Fixing of a multilayer glass fibres NCF by adhesive application; Middle: Adhesive fastened glass NCF; Right: Adhesive pattern on a carbon fibre NCF

Materials

High-performance fibres. The typical used high-performance fibres for NCF are based on carbon or glass. They exhibit high mechanical load bearing properties [4], especially carbon fibres. Both fibre types differ in the inner structure, glass fibres (GF) are defined by an amorphous structure and carbon fibres (CF) by an anisotropic graphite lattice [3]. In this work, the used CF were HTS 45 E23 (epoxy sizing), HTS 40 F13 (polyurethane sizing) and UMS 40 F23 (polyurethane sizing), all purchased from Toho Tenax, Germany. The used GF types were EC 600 350 and EC 600 354 with different silane sizings supplied by P-D Glasseiden GmbH, Germany. In general, the surface chemistry of CF is often driven by the applied sizing. Without such a sizing, the CF is characterized by acidic surface groups like carboxylic and hydroxylic groups [4, 5]. The mechanical properties of the used yarns are presented in Table 1. The diameter of the single filament of a carbon fibre was determined by a light microscope. The surface energy was measured by single fibres tensiometry as explained below.

Table 1: Properties of used carbon fibres

Typical properties		**Tenax®-E HTS45 E23**	**Tenax®-E HTS40 F13**	**Tenax®-J UMS40 F23**	**EC 600 350**
Sizing		PU-sizing	EP-sizing	PU-sizing	silane sizing
Linear density	[tex]	796.4	800.3	797.6	600
Grade	[K]	12	24	12	9

Diameter of single filament (average)	[µm]	6.19	4.40	6.30	20.6
Surface energy, total	[mN/m]	39.9	43.3	45.9	53.4
Surface energy, polar	[mN/m]	6.5	9.7	10.7	9.3
Surface energy, disperse	[mN/m]	33.4	33.6	35.2	44.1

Adhesives. The existing warp-knitting process gives well and narrowly defined specifications for the binding system and adhesive, respectively. Firstly, the present machine speed determines the potential curing time of the adhesive. Secondly, there are only a few installation options at the multiaxial machine for the application of the adhesive. Additionally, a couple of chemical aspects are important: The adhesive has to be suitable for the surface of the carbon or glass fibres, which are often sized with polyurethane, epoxides or silanes. Furthermore, the adhesive has to be compatible with the reinforcement matrix, i. e. epoxides or polypropylene. For a later forming of NCF in special geometries, it has to be considered to activate the adhesive by wetting or heat. Caused by the capillarity of the high-performance fibres, the viscosity of the used adhesive is of interest.
Different adhesives were investigated: Polyolefines B 42042 and B 41742 (Bühnen, Germany), the cyanoacrylates Delo 2351 and Delo 2219 (Delo, Germany) and Loctite 3090 (Henkel, Germany), 2K-Methylmethacrylate adhesive as 'Carbon Kleber' (Carbon Team), thermoplastic acrylate J 41619 (Bühnen, Germany) and copolyester hotmelt adhesive D 2351 E as granulates and as suspension (EMS Griltex, Switzerland) [6].

Matrix. The adhesives were embedded in a conventional thermosetting matrix based on epoxy resin MGS® RIM 135 (L135i) and the curing agent LARIT RIMH 137 (Lange + Ritter, Germany). The samples were cured out at room temperature.

Methods

Wetting Studies. Two different types of wetting studies were performed. First, the drop shape analyzer DSA 100 (Krüss GmbH, Germany) method was used which operates with a resting drop on an ideally, smooth and solid surface. This method estimates the wetting and adhesion on a solid surface. The contact angles of the high-performance fibres were determined by the single fibre tensiometry, Krüss K100 (Krüss GmbH, Germany) which works in accordance to the Wilhelmy plate principle [7]. In each case, the contact angle is a determining factor of the degree of attraction of the liquid by the substrate. The surface energy (γ) is composed of two components: The polar (^{p}) part is induced by dipol-dipol and acid-base interactions as well as hydrogen bonds. The disperse (^{d}) part is mainly driven by van-der-Waals forces [8].

Surface Modification of High-Performance Fibres. To increase the number of surface functional groups of carbon fibre, several methods were used. Firstly, the carbon fibres were treated with an atmospheric plasma torch (Plamsa Brush® Pb2, Reinhausen GmbH, Germany) fed by different process gases i. e. Argon, compressed air and Nitrogen. Another method to increase the surface energy was the use of oxi-fluorination. The oxi-fluorination was done by 10 Vol% fluor gas in the presence of oxygen (Fluor Technik System GmbH, Lauterbach/ Germany).

Scanning Electron Microscopy (SEM). The SEM was used to observe the fibre surface in the micrometre range. The measurements were performed with a high resolution low-voltage SEM with a field emission cathode Zeiss DSM 982 Gemini.

Results

Surface Morphology of High-Performance Fibres and Surface Modification. To understand the wettability by an adhesive, the morphology of the adherend has to be known. Therefore, the high-performance fibres were investigated via SEM. Exemplary, a single filament of a ultra-modulus carbon (UMS 40 F23) fibre is presented in Figure 3. In general, CF exhibits parallel oriented stripes and striations. These surface morphologies are probably caused by stretching of the fibrous

polyacrylonitrile precursor [4]. Often, this rough texture is filled by the used sizing, i. e. polyurethane (PU) or epoxy (EP). In the case of a surface treatment, the surface morphology changes significantly: Parallel striations and other roughness effects disappear during surface treatment. For example, the surface looks flatter and the sizing seems to be removed, because the irregularities became more substantial after removing the sizing (Figure 4).

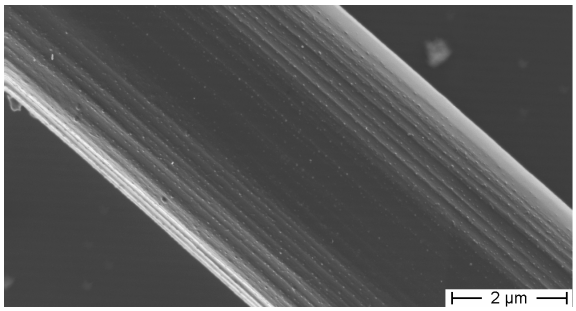

Figure 3: Ultra-modulus carbon fibre (UMS 40 F23)

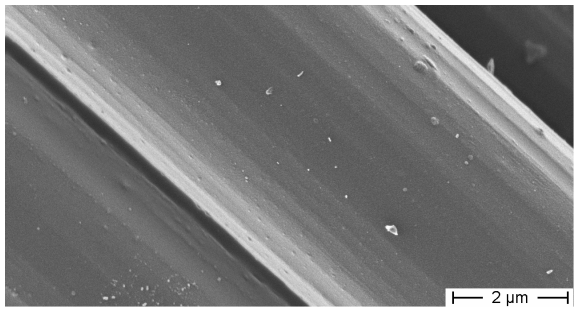

Figure 4: UMS 40 F23 treated with argon plasma

This assumption is supported by the finding of a reduced polar energy after atmospheric argon plasma treatment. The carbon fibre HTS 45 E23 exhibited a polar surface energy of 6.5 mN/m (in Table 1). After a short processing time, the polar energy increased and the sizing was functionalized. With increasing process time, the sizing was removed and the polar surface energy decreased to 6 mN/m. However, with passing time the polar surface energy increased again to 12 mN/m. In this case, the original carbon fibres surface and not the sizing received new functional groups, which were determined by the increase of the surface bound oxygen measured with X-ray photoelectron spectroscopy.

Wettability Studies. A good wettability of components to each other is realized, if the total surface energy (sum of polar and disperse) is comparable or the same, respectively. In regard to Figure 5 and Table 1, the surface energy of carbon fibres is around 40 mN/m to 46 mN/m.

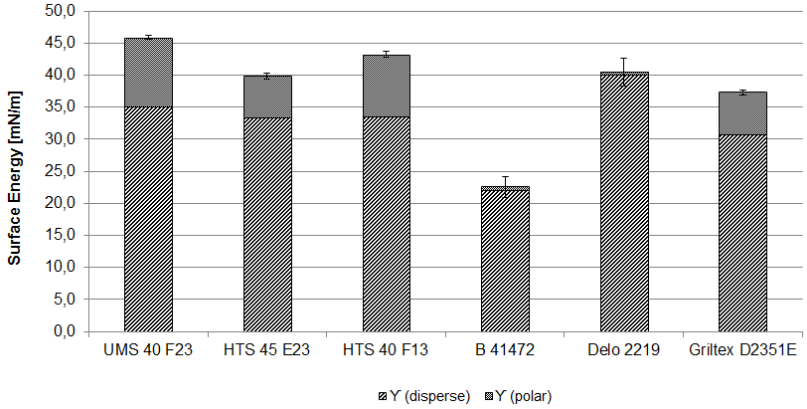

Figure 5: Surface energies of selected carbon fibres and possible adhesives

Furthermore, a selected number of potential adhesives are presented in Figure 5: B 41472 (polyolefin) and Griltex (copolyester) D 2351 E are typical hotmelts. Griltex D 2351 E exhibit a very high polar surface energy of 6.9 mN/m which indicates a high number of polar surface functional groups compared to the polyolefin hotmelt B 41472 with a polar surface energy of 0.6 mN/m. Another promising adhesive is the Delo 2219 (cyanoacrylate) which has a high total surface energy. Both binders, the Griltex D 2351 E and Delo 2219 were investigated successfully by tensile tests of glued high-performance yarns. Moreover, both adhesives are suitable for the used epoxy matrix. Therefore, they will not represent weak points that introduce fractures in a carbon fibres reinforced plastic.

Conclusion and Outlook

This fundamental work was done to achieve the innovative goal of a novel manufacturing technology for NCF. Different adhesive systems were investigated to find the optimal binder system for the non-stitched NCF. Limiting factors of process and chemical properties were considered and two adhesives were sorted out. They exhibit a short curing time and easy handling. The Griltex D 2351 E hotmelt is preferred for realisation of the new type of NCF. This binder can be implemented with the developed technology to achieve the desired structures. To improve the wettability of the fibre by the adhesive, different surface modifications were performed successfully, i. e. plasma treatment and oxi-fluorination.

Keywords: Warp Knit Fabric, Multilayer Fabric, Non-Crimp, Stitch-Free Fabric, Composite

Abstract: In the field of technical textiles, Non-Crimp Fabrics (NCF) are increasingly used as fibre-reinforced polymers in automotive, aircraft and wind power industry. The rising consumption of multi-axial fabrics for fiber reinforcement requires new fabrics and process requirements for the large scale production. The development of a new type of NCF demands a convergence of diverse disciplines namely mechanics, construction design and chemistry. This research includes the manufacturing of novel adhesive bonded NCF. The characterization and of the warp-knitted fabric, selection of binding technology, the development of suitable application system and numerical models for simulation are the major focus areas.

Introduction

Fiber-Reinforced Plastics (FRP) made of high-performance carbon and/or glass fiber textiles are increasingly used in various technical applications like automotive-, aeronautics and aerospace industry, mechanical engineering and civil engineering. Especially NCF produced on multi-axial warp-knitting machines are characterized by an excellent property profile combined with a high production rate and lead to novel developments. In the conventional manufacturing process of NCF, the reinforcement fibers are placed in parallel layers, each with a different specific orientation. In the consecutive step, these yarn layers are fixed by a binding thread during a warp-knitting process [1]. Hereby, the penetration of the material by the stitching needles damages the fiber material of NCF. This causes defects like gaps and fish-eyes which affect the load-bearing properties and creates weak area in the structure by inclusions of resin [2], shown in Figure 3. These defects are highly connected to the inner tension of the binding thread systems. In addition microscopic studies have also shown that these defects represent a weak area in reinforced materials where the resin can accumulate. Such issues lead to a decreasing quality of the final FRP product.

Technological Challenges and Requirements

The development of a new generation increased quality NCF require that some base conditions must be maintained. In addition to a fiber-friendly manufacturing process and associated decrease of fiber damages and deflections, the process must be comparatively productive to the conventional manufacturing process. For this reason new bonding technologies for oriented fiber layers are developed. These are based upon the local applied suited adhesives between the single fiber layers of the NCF. The used binder materials have to be adapted to different fiber materials as well as to their corresponding application system.

For the realization of this adhesive-based production approach, a patent for injection of adhesive into the unbound layers of oriented fibers has been registered. Multiaxial non-crimp fabrics are locally bonded by injecting very small adhesive droplets/microdroplets [3]. This binding system replaces the warp knitting yarn, which usually form loops around the fiber layers in order to fix the different layers. The current approach aims on a localized application and fixation by suitable chemical binders. The substitution of the knit yarn system with adhesive binders improves upon the current disadvantages of the stitch bonding technology. Figure 2 shows a sketch of the novel production technology. The arrangement of the adhesive nozzles is displayed. The adhesive system

can be seen here infiltrating the previously deposited layers by the nozzle-system. For laying the fibers on top of each other the existing system of the warp knitting machines of Karl Mayer (Germany) can be used. Either after the laying process or between every layer, the nozzle-system can induce the binder according to a computational pattern plan as shown in Figure 1.

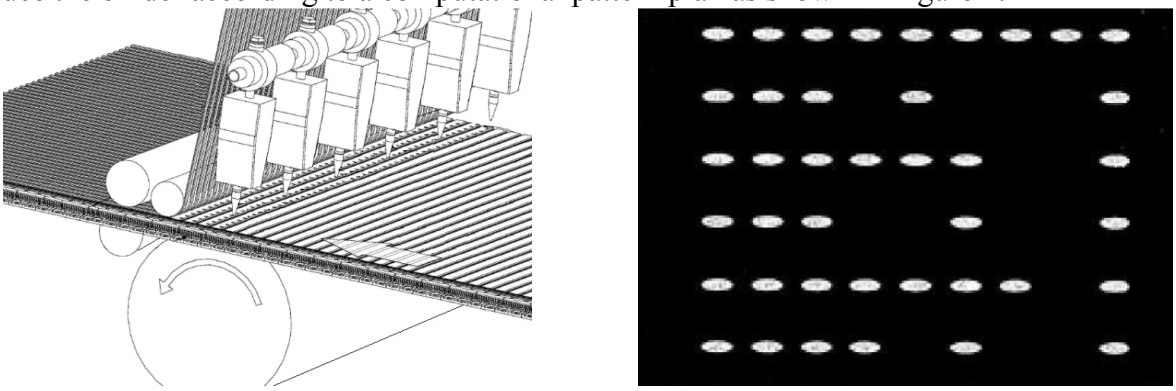

Figure 1: Left: Schematically principle of novel technology for yarnless layer binding by adhesives, Right: Sample pattern plan [2]

Technology Development

The binding of layers with a suitable adhesive system require an understanding of the bonding process, application technology and the surface properties of adhesives and fiber. In order to retain the fiber characteristics, a micro-scale application of the adhesives is essential. This can be only fulfilled using a high frequency application technique. Besides, process stability, durability and maintenance form a decisive factor in the selection of this technology. The modularity and flexibility for the integration with the common fiber laying system on the machine is also needed to be considered. Different systems were tested for upon these requirements to evaluate their suitability.

Studies were carried out on the application system with respect to the speed and their positioning accuracy. The dimension and the mass of the adhesive micro-droplets together with the speed of application were evaluated. It is required that the nozzle injection must ensure a fast and accurate binder infiltration in the fiber and between their layers. These analyses were experimentally carried out using a portal application system. The ability of the nozzle-systems was also investigated with this system in order to create accurate and reproducible samples which are shown in Figure 2.

Figure 2: Left: Portal system; Middle: Nozzle system; Right: Produced samples after binder activation

Manufacturing of Sample Structures

To validate the achieved results on the adhesive binder system and the chosen application technology, samples were manufactured on a laboratory scale. Figure 3 shows two produced specimens with two adhesive dot patterns which vary in their binding dot density. The achieved production speed was sufficient and the quality of the fixation was as expected. At this point of research, data about the mechanical behavior are still pending. Examinations concerning the

influence of the adhesive binder material in a cured composite will be done in addition to the economic analysis concerning the efficiency of this new technology. Figure 3 also shows the proof that some of the disadvantages of the classic production (Figure 3, left) technology can be eliminated by the novel introduced approach. A four layered fabric is fixed by a pattern of adhesive dots. It is clear to see that there is nearly no displacement of the fiber layers and no formation of fish eyes.

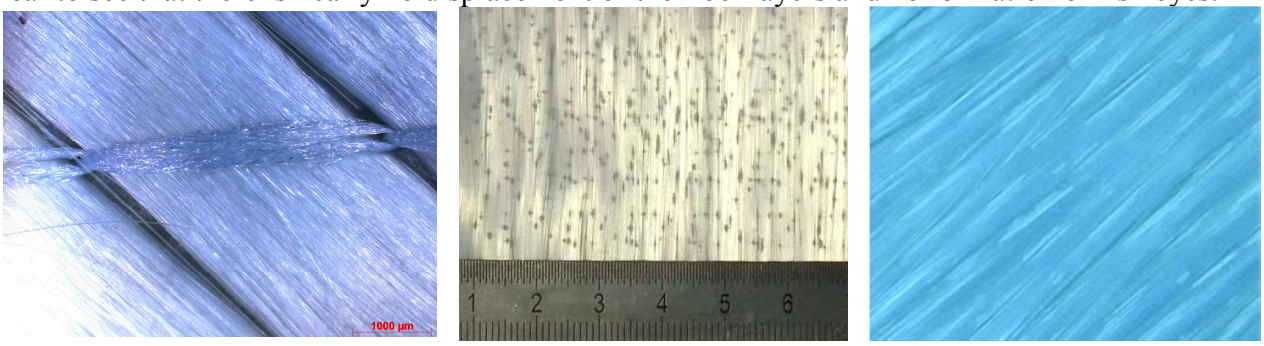

Figure 3: Left: NCF with fish-eye, Middle and Right: Produced multilayer adhesive bonded fabrics

Simulative Development of the Non-Crimp Fabric Structure

To support the development of the introduced production technology, simulative analysis will be done. With the help of numerical finite element models and simulations, knowledge about the structural behavior of fibrous materials interacting with cured adhesive dots will be generated. After successfully implementing a structural model with its characteristics, large scale models of the non-crimp structure with near microscopic resolution will be generated to examine the deformation behavior of the novel textile structure under deforming conditions. Deformation mechanisms on the yarn- and even on the filament-level will be investigated to qualify the novel textile structure with regards to micro- and meso-deformational effects.

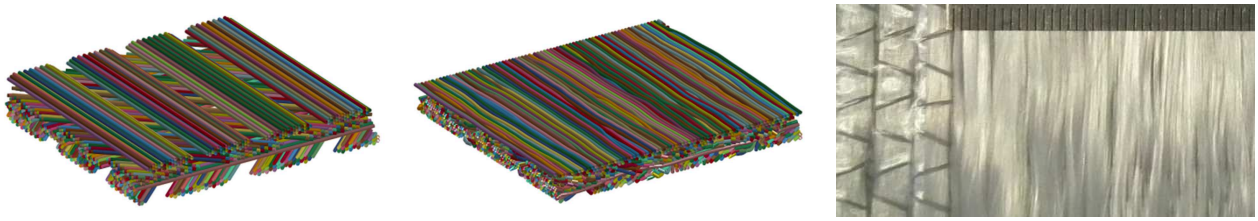

Figure 4:Unit cell model of 4 layered NCF before and after compaction
(right side: real structure without knitting yarns or adhesive dots)

For the model of the yarn layers, a near micro scale resolution was chosen to enable the analysis of inter and intra yarn effects. To handle this model and the accompanying computational costs, some simplifications have to be made. For this purpose, the digital element approach introduced by Wang and Sun [4] was chosen.

It is obvious, that not every single filament of a technical 12K glass-roving can be represented by a single digital element chain but a sufficient large number of these element chains are enough to satisfyingly represent a multifilament yarn [5]. For the introduced simulations, an amount of 39 digital element chains per yarn were chosen. Figure 4 shows the model of a unit cell which represents a four layered fabric. At the beginning of the simulation, the yarns are arranged in four different directions. The result of this simulation shows the alignment of the fiber bundles after compacting the structure without any bonding from knitting yarns or adhesive dots. As seen on the right hand side of Figure 4, the shape of the yarn traces matches the reality when the yarns are not bounded anyhow.

To gain knowledge about effects that occur while forming a textile structure with the introduced properties, a large dimensional model will be assembled. Not only results about effects on the filament level shall be obtained, but statements and suggestions about the adhesive dot pattern shall be created virtually with the help of such a mesoscopic model. The adhesive dots can be placed individually regarding the infiltration depth and the pattern. Variations in adhesive mass and dots per

inch can be made. Obviously, the adhesive dot concentration and the adhesive mass per unit cell have a significant effect on the local forming ability of the structure. Hence the influence of the adhesive injection process and its parameters shall be analyzed virtually to reduce cost intensive production and examinations. With knowledge about the adhesive influencing the deformation behavior, suggestions about local fixation patterns and the local adhesive amount can be made after analyzing the deformational process.

Conclusions

A suitable technology for the fixation of NCF by adhesive was adapted. The solution is based on systems that are available on the market, which enables options for integration in a large scale production technology on any multi-axial warp-knitting machine. Considering the lifetime of the nozzles, this is very important to guarantee a robust implementation of the technology and also to enables a user friendly attendance. Topics for further research will be the implementation in a non-laboratory dimension. Here economic aspects concerning the use of more than one nozzle and their controlling as well as the cost effectiveness of the resulting product has to be investigated.

All the examinations and investigations dealing with the analysis of suitable adhesive binder materials and sufficient application technologies to achieve a competitive reinforcement product for the use in large scale structural parts made out of composite material, done presently, ended in a successful preparation of loop less multilayer fabrics fixed with chemical adhesive binder materials. Disadvantages of the classic NCF production technology were eliminated and the produced samples were suitable for reinforcing thermoset matrices.

Keywords: INA-V drafting, Pressure bar, Break drafting ratio, Roving twist factor, Yarn quality.

Abstract: To improve the yarn quality, the pressure bar was installed in the break drafting zone of the INA-V spinning frame. The process parameters were optimized in the break drafting zone with pressure bar of the INA-V spinning frame, the drafting principle in the break drafting zone with pressure bar of INA-V spinning frame was analyzed, and the sliver configuration was observed in the break drafting zone with pressure bar. The result revealed that installed the pressure bar in break drafting zone after, when the roving twist factor was small, CV%, thinness, thickness and neps of the yarn spun decrease as the break drafting ratio increase; when the twist factor of roving was larger, the break draft ratio as 1.3 time was optimum drafting conditions. The yarn quality was improved as roving twist increased.

Introduction

Research shows that, in the break drafting zone additional pressure bar of INA-V spinning frame can improve the yarn evenness, reduce yarn thickness and thinness [1-8]. But, after additional pressure bar in the break drafting zone of INA-V drafting frame, the conditions of spinning changes, in order to further improve the yarn quality, we must optimized parameters. Based on analyzing drafting principle of the break drafting zone with pressure bar of INA-V drafting frame, experimental studied the effect of the different break draft ratio and roving twist factor to the yarn quality. Through defined reasonable spinning process parameters, to obtain the higher quality yarn.

Drafting Principle

The position of the pressure bar and roller center distance shown in Fig. 1.the diameter of the pressure bar is 6 mm ,the distance between the pressure bar center and the roller center is 24 mm, and the vertical distance from the middle roller is 18mm.

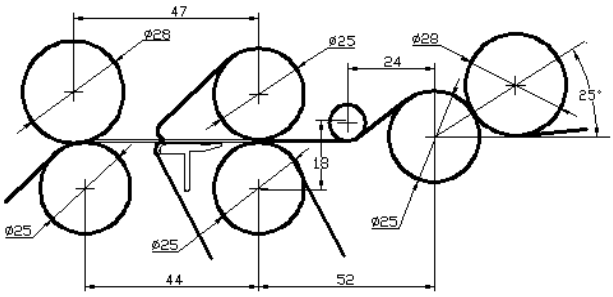

Fig. 1. The position of the pressure bar in break drafting zone

After additional pressure bar in the break drafting zone of INA-V drafting frame, the parameters such as the frictional force field distribution, the drafting force and the roving twist distribution will change.

Variety of Frictional Force Field and Drafting Force

After installing pressure bar in the break drafting zone, not only eliminate the back-surrounded arc on the middle roller, but also further expand the length of surrounded arc on the rear roller. Through calculated we can see: the length of surrounded arc of on the rear roller become 25mm from 20mm; simultaneously, the fiber strand is formed a surrounded arc about 6mm on the surface of the pressure bar, which make the friction force field strengthen and expand into the middle nip. The drafting force and its peak value are augmented, the critical drafting ratio increased too. At the same time, the drafting force wave is decreased, which is benefit to improving and stability of yarn quality.

Twist Distribution

In the break drafting zone, the fiber strands straighten and moved under tension. Thus, the roving strand is untwisted, and the twists transfer to the middle roller nip, it make the twists increase near the middle nip, and the twists decrease near the rear roller, that is the twists redistribution. Twists redistribution phenomenon makes the middle friction force filed weaken, the roving strand become loose, and it is unfavorable for improving yarn quality.

After installing pressure bar in the break drafting zone, the surrounded arc which is formed on the surface of pressure bar prevent the writhe of the roving, and the twists transfer to the middle roller gradually, thus it will decrease the twists redistribution phenomenon. Because the pressure bar has the function that prevent untwist and decrease the twists redistribution, the remaining twists in the break drafting zone can transfer to the front drafting zone, and make the fibers produce centripetal force in the up-down aprons. Thus, the compactedness and friction field are strengthen, and the fiber accelerated point approach to the front roller nip, the yarn quality can be improved.

Making use of the camera to photograph the roving strand in the drafting process, we can see that the stands distribution state with the pressure bar or no shown in Fig. 2 and Fig. 3.

In Fig. 2, when no pressure bar, the twists of the fiber stands almost disappear in the break drafting zone; On the contrary, when installing pressure bar in the break drafting zone in Fig. 3, due to the fiber stand contact with the pressure bar closely, it cannot be untwisted freely in the break drafting zone; According to the actual observation, when the twist factor of roving is 117, there are about 1.5-2 twists.

In a word, after installing pressure bar in break drafting zone of INA-V spinning frame, because the frictional force field, the drafting force and the compactedness of the fibers increase in the front zone, we must optimized parameters such as the break drafting ratio, roving twist factor and so on, otherwise, the drafting force and gripping force discordance and it will produce serious thickness, thinness, unevenness.

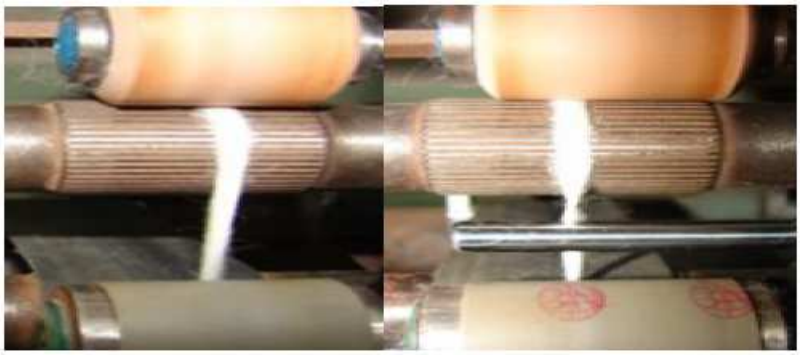

Fig. 2.The roving strand distribution Without t pressure

Fig. 3.The roving strand distribution bar with pressure bar

Experimental

Materials

The cotton we used has the following specifications:0.14tex, 5% of the span length for 35.12 mm, 50% of the span length for 23.43mm, effective length for 30.90mm ,the short fibers content that under the 16mm of 18.73%(n), the roving for 452tex,the neps count for 18 neps /g, CV% of the roving is 7.85%.

Experimental conditions

The SDDA2122P(D) type pneumatic weighting cradle was used in spinning frame. 20.2tex cotton yarn were spun on a laboratory spinning frame with the INA-V drafting system under the following conditions: the front roller center distance for 44mm, the rear roller center distance for 52mm, the apron nip for 3.0mm, the front roller pressure for 180N, the roving twist factor for 97,117, the break drafting ratio1.1, 1.2, 1.3, 1.4, and 1.5 respectively, spinning speed for 13000 rpm, OSS traveler.

Test equipments

Yarn quality such as CV%, thickness (+50%), thinness(-50%), and neps (+200%) was tested with the YG135 tester; Yarn breaking strength (cN/dtex) was tested with the INSTRON5582 strength tester; Yarn hairiness index(3mm)was tested with the YG172 hairiness tester.

Results and Analysis

When the apron nip is 3.0mm, the roving twist factor is respective 97 and 117, and the break drafting ratio is respective 1.1~1.5, the relationship between the roving twist factor and evenness thickness, thinness, hairiness index and strength shown in Fig. 4~Fig. 9.

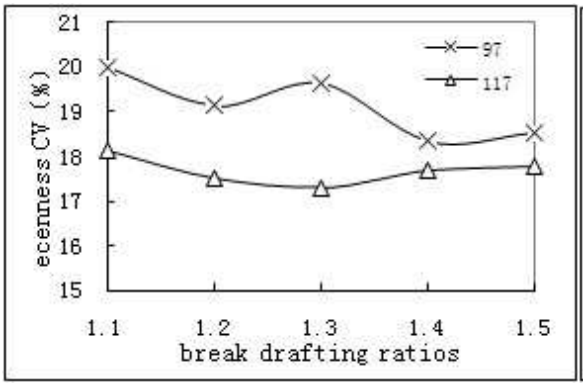

Fig. 4. Evenness CV%

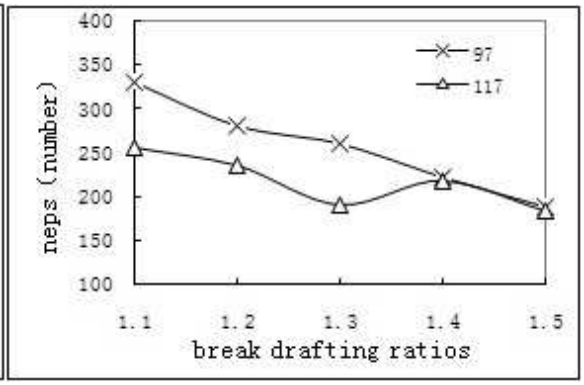

Fig. 5. Neps

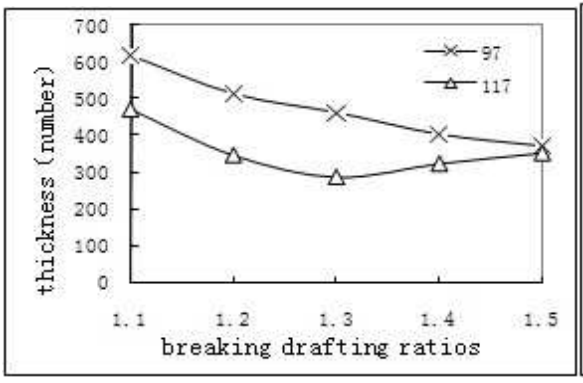

Fig. 6. Thickness

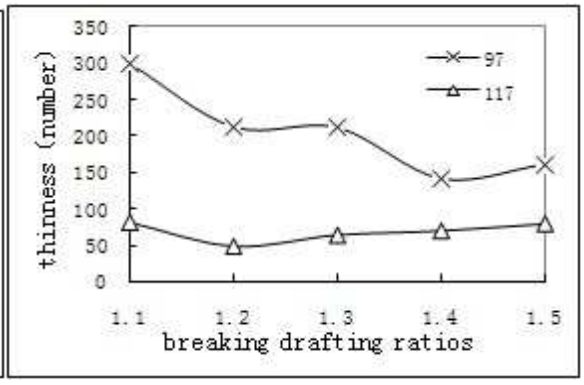

Fig. 7. Thinness

Compared the roving twist factor for 117 with 97, the evenness , thickness, thinness, neps and strength is improved significantly, which shows after installing pressure bar in the break drafting zone of INA-V spinning frame, adopting larger roving twist factor, not only enhances friction force, but also can make partial twists enter the front drafting zone. Thus, the compactedness and friction force of the fiber strands is increased in the front drafting zone, and strengthen the control to the fiber movement.

When the break drafting ratio changes from 1.1 to 1.5 time, the yarn quality is different in the laws of Change with the roving twist factor. When the roving twist factor is 97, CV%, thickness, thinness and neps almost all improve with the breaking drafting ratio increasing. However, when the roving twist factor is 117, CV%, thickness, thinness and neps increase after decrease with the break drafting ratio increasing; at 1.3 time the minimum when it has.

When the roving twist factor is smaller, the larger break drafting ratio is conducive to improve CV%, thickness, thinness and neps. When adopted the larger roving twist factor, the breaking drafting ratio has little effect on the yarn quality. Because after installing pressure bar in break drafting zone, the drafting force and its peak value are augmented, the critical drafting ratio increased also. At the same time, the drafting force wave was decreased, which is benefit to improve the yarn quality. This also shows that after installing pressure bar in break drafting zone of INA-V spinning frame, larger break drafting ratio is feasible.

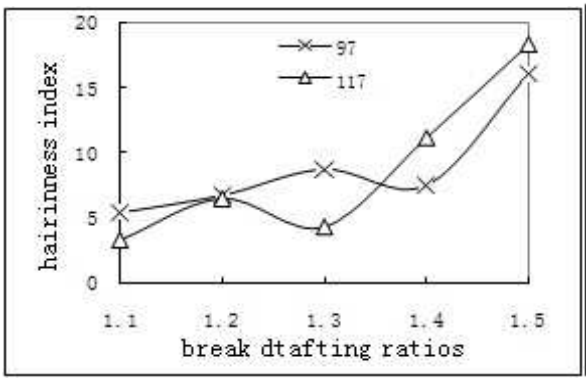

Fig. 8. Hairiness

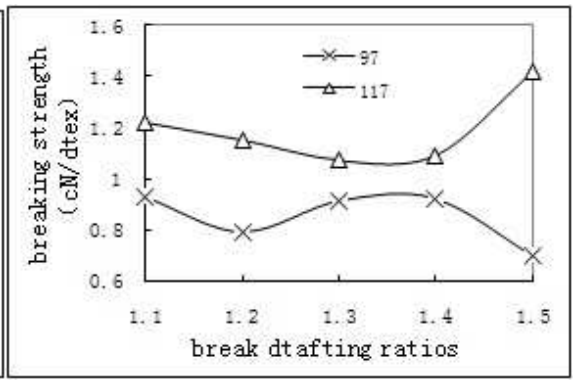

Fig. 9. Breaking strength

The roving twist factor changes in yarn hairiness index of no significant impact. When the break drafting ratio more than 1.4 time, the hairiness index increased significantly.

The larger the roving twist factor, the higher the yarn strength. The yarn strength increase after decrease with the break drafting ratio increasing, at 1.3 time the minimum when it has.

Conclusions

After installing pressure bar in break drafting zone of INA-V spinning frame, there are following characteristics:

Appropriate increase the roving twist factor, enabling improve the yarn quality such as CV%, thickness, thinness and neps and yarn strength.

When adopted smaller roving twist factor, CV%, thickness, thinness and neps almost will decrease with the break drafting ratio increased. When larger roving twist factor, CV%, thickness, thinness and neps increase after decrease with the break drafting ratio increasing, at 1.3 time the minimum when it has. Therefore, after installing the pressure bar in break drafting zone adapt to the larger break drafting ratio.

The effect of roving twist factor is not obvious to yarn hairiness index. When the break drafting ratio is more than 1.4, the yarn hairiness index will be increased significantly.

Non-isothermal Resistance Heating for Hot-stamped Parts with Tailored Properties and Tempering Treatment on Directly Hot-stamped Parts

SUN Caina[1, a] and Zhang Henghua[1,b]

[1]School of Materials Science and Engineering, Shanghai University, Shanghai 200072, China

Keywords: 22MnB5 steel, Hot stamping, Resistance heating, Tailored properties, Tempering treatment

Abstract. Non-isothermal resistance heating in the hot stamping of quenchable steel sheets was developed to produce ultra-high strength steel formed parts with tailored properties. The heating temperature of parts is related with width of samples heated by resistance heating. With the same input energy, the strength in the narrow portions is high owing to the high energy density and that in the wide portions is low owing to the low energy density. Hat-shaped products having a tensile strength arrange from 600 MPA to 1800 MPa were formed. The tempering treatment on the directly hot-stamped boron steel resulted in better mechanical properties and higher formability index. The SEM figures indicates that the nano-carbide formation during the tempering treatment were suggested as the evident reasons for the occurrence of the mentioned robust properties. Finally the combination of temperature 250 ℃ and holding time 45 min can achieve the best comprehensive mechanical properties.

Introduction

In the hot stamping, a whole body of parts is conventionally quenched with dies, and thus the whole body becomes highly strong. This leads to the limitation of application to high strength body panels having high crash safety for protecting passengers. But an improved crash performance of a vehicle structural component can be achieved by introducing regions which have an increased elongation for improved energy absorption. The manufacturing of a single part with tailored properties can be carried out using different process control strategies or tailor welded blanks[1-2]. In the present study, Non-isothermal resistance heating in the hots tamping of quenchable steel sheets was developed to produce ultra-high strength steel formed parts with tailored properties.

The lower toughness originates from the martensitic microstructure of the hot-stamped parts. XIN Peisen[3] recently managed to enhance the mechanical properties of the indirectly hot-stamped 22MnB5 steel using the quenching and partitioning (Q&P) process. They successfully generated a high product of tensile strength and ductility which is increasing 24% than the traditional hot stamping material. In the current work, in a new attempt, the effects of the tempering process on the microstructure and the mechanical properties of directly hot-stamped parts made of boron-alloyed steel were investigated. The hot stamping process was followed up by the tempering treatment for the various combinations of temperatures and holding times.

Non-isothermal Resistance Heating

Materials and procedures. The quenchable steel sheet 22MnB5 (C: 0.23%, Si: 0.26%, Mn: 1.1%, Cr:0.182%, B: 0.0038%) having 1.5 mm in thickness was employed for this experiment. The Vickers hardness of the as-received sheet was 229 HV.

Resistance heating method is to heating steel sheets by sandwiching with a pair of electrodes and it is sensitive to the sample size (length / cross section ratio)[4]. The heating temperature is related to cross-section, in other words, is related to width as the thickness is given due to per unit volume input energy is different. It is possible to obtain desirable heating temperature of the sample by varying the width of material. So parts with tailored properties followed by hot stamping can be obtained. The relationships between the Vickers hardness and properties versus the hating temperature and width of

samples are illustrated in Figure1. As described above, samples for non-isothermal resistance heating are designed as Figure 2. The length of the sheet is 200 mm and the distance between the two electrodes is 120mm. The width of the left 80 mm part is 10 mm and of the right 80 mm part is 12 mm. The width of the middle 40 mm is continuously changing from 12 mm to 10 mm. Thermocouples are welded on different parts to detect temperature. After hot stamping Vickers hardness are measured. The hardness detective pots on the surface of samples are illustrated in Figure 2.

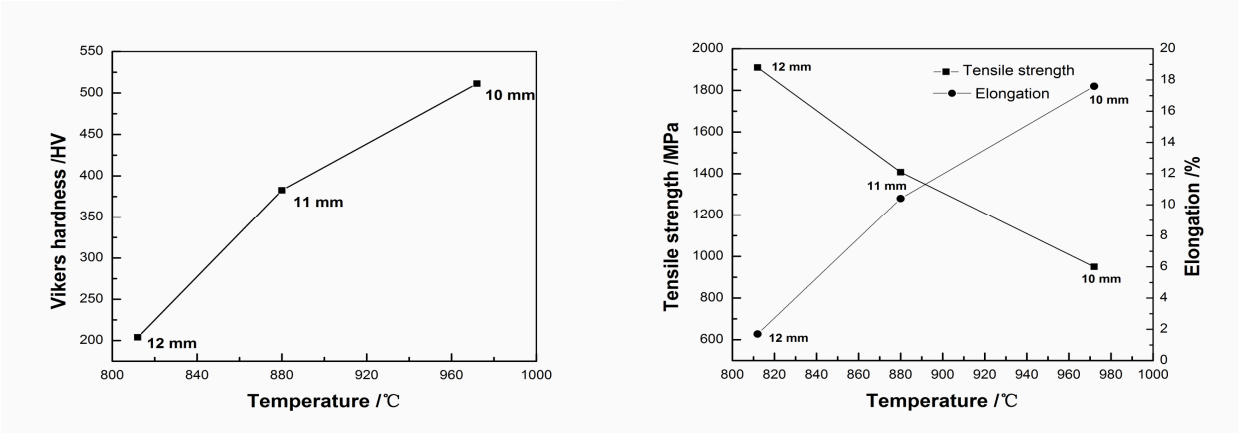

Fig.1 Relationship between Vickers hardness and properties versus the hating temperature and width of samples.

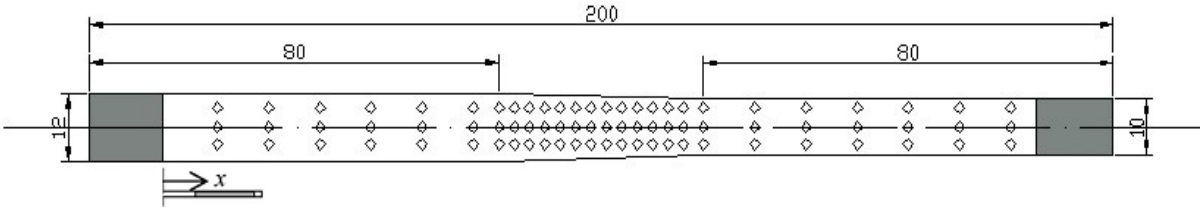

Fig. 2 The size of samples /mm

Results for non-isothermal resistance heating. The distributions of temperature in the longitudinal direction on the surface of the sheet measured by thermocouples are illustrated in Figure 3(a). Heating temperature varies with the changing width transition area of the sample which is about a linear relationship. The distributions of the Vickers hardness and microstructure in the longitudinal direction are shown in Figure 3(b). The hardness increases as the heating temperature increases. Temperature is above 950 ℃ and hardness is about 500 HV with the width 10 mm. And temperature is about 810 ℃ and hardness is about 220 HV for the width of 12 mm. In the transition zone, the hardness is changing slowly and flexibly depending on the changing slope of the temperature. Therefore, the tailored properties of samples can be obtained. When temperature is below the critical transition temperature, the microstructure of sample is same as the sample as-received containing about 75% ferrite and 25% pearlite. With heating temperature increasing, parts of pearlite began to transform into austenite and interface between pearlite and ferrite began to blur until finally completely transformed into austenite. Then martensite attained after quenching. The distributions of tensile strength and elongation of samples are given in Figure 3(c). The tensile strength in the high temperature portion is about 1800 MPa, and elongation is about 5% whereas tensile strength in the low temperature portion is about 600 MPa and elongation can reach 18%. In the intermediate transition zone the tensile strength and elongation of samples must changed continuously according to the change of hardness.

Tempering Treatment

Experimental Process. Some of the direct hot-stamped specimens were selected to undergo the tempering treatment. Tempering treatments at four different temperatures of 200℃, 250 ℃, 300 ℃ and 350 ℃ were performed for different holding times of 5, 15, 30, 45, and 60 minutes. All the tempering treatments were conducted in a furnace with a non-protected atmosphere.

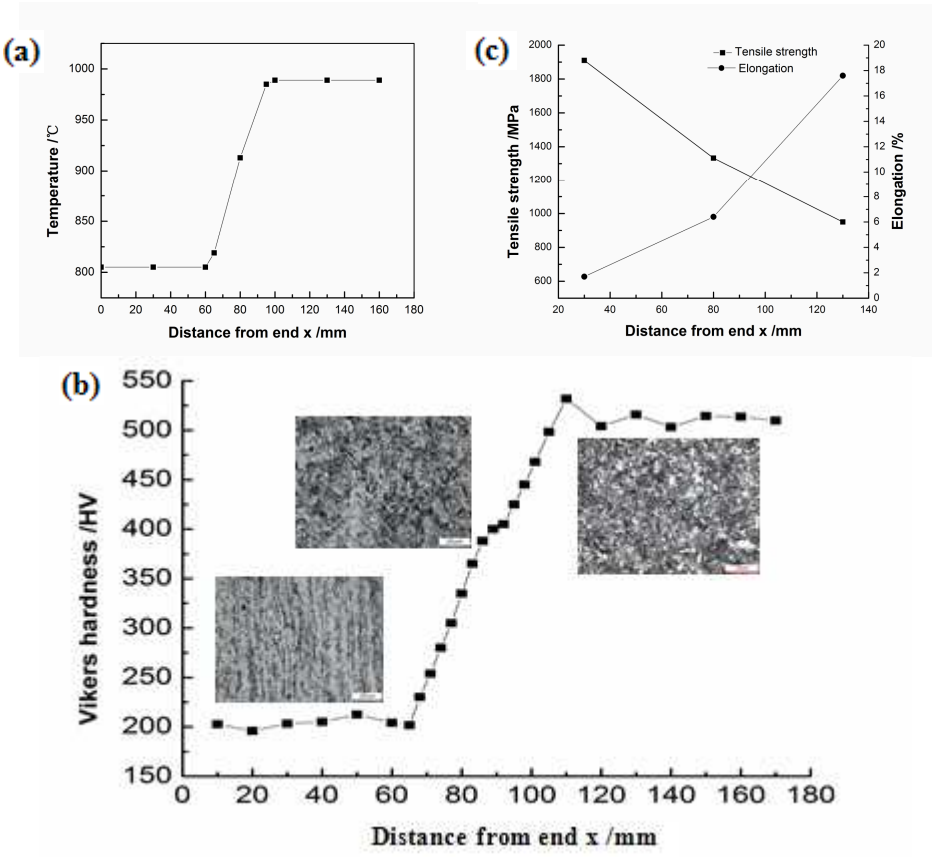

Fig. 3 Temperature, hardness and tensile strength versus distance from end

The microstructure of the samples processed under different conditions, hot-stamped as well as hot-stamped and subsequently tempered, respectively, were evaluated by OM and SEM. For the OM analysis, Nital was used as the etching agent by which ferrite, bainite, and martensite phases can be detected. The microstructure of the steel was characterized by a SEM after the conventional Nital etching. The mechanical properties of the processed samples were determined by tensile testing using disproportional samples due to the resistance heating samples are very small.

Results and Discussions for Tempering Treatment.

Microstructural Investigations. The OM microstructural changes during the tempering treatment are presented in Figure 4. A clear lath martensitic microstructure is representative of the hot-stamped specimen, while this characteristic began to blur in the microstructure of the tempered 5 minutes specimens. The SEM images of hot-stamped as well as hot-stamped and tempered specimens are compared in Figure 5. While the needle-like microstructure is observed for the quenched steel (Figure 5(a)), the micrograph of the quenched and tempered specimen (Figure 5(b,c)) clearly demonstrates the carbides precipitation. This observation agrees with well-known phenomena occurring during the tempering process in which carbides constitute, and a needle-like martensite phase is replaced by equilibrated phases (ferrite and cementite)[5].

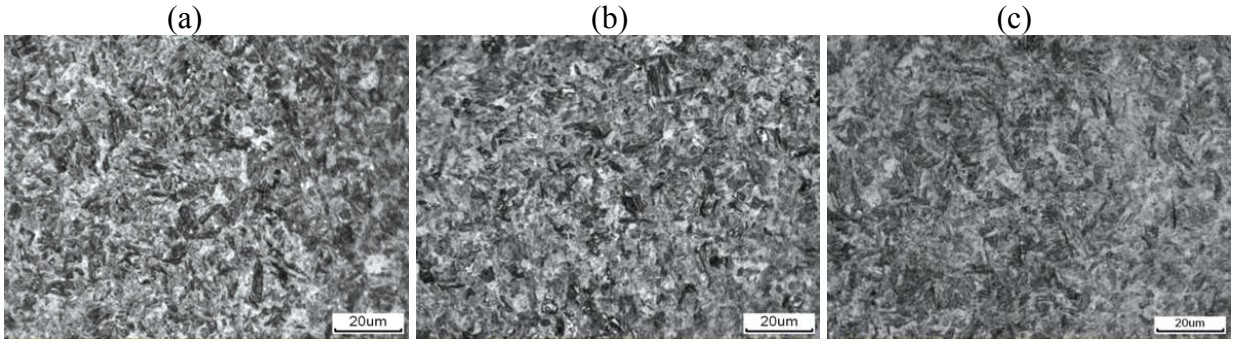

Fig. 4 OM microstructure images of (a) hot-stamped specimen, hot-stamped specimen and tempered at 250 ℃ for (b) 5 min, (c) 60 min

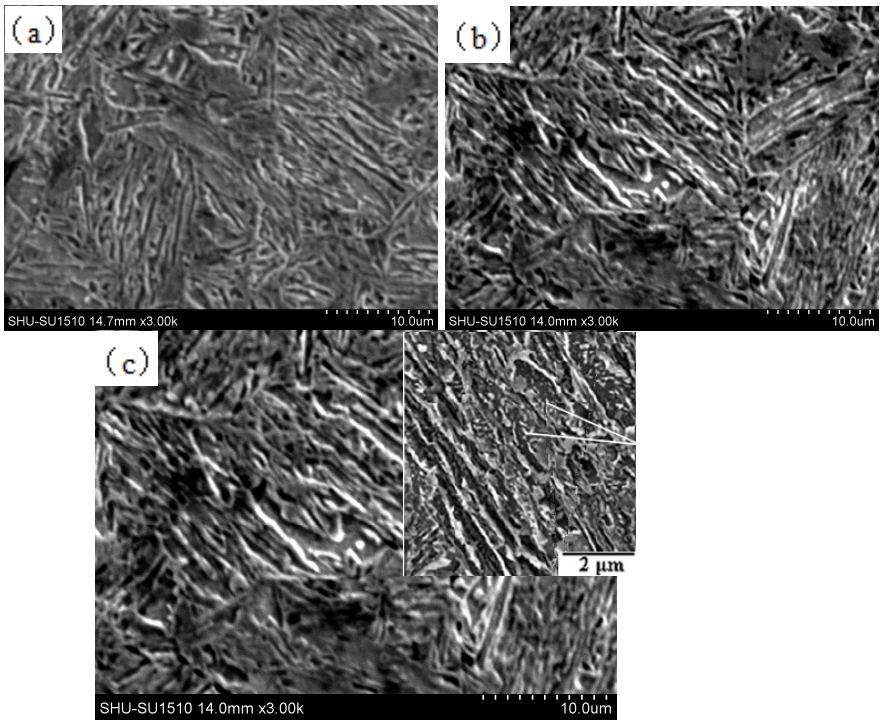

Fig. 5 SEM images after (a) hot stamping, (b, c) hot stamping + tempering at 250 ℃for 15 min.

Mechanical Properties. The mechanical properties of the studied specimens are represented in Figure 6. Tensile strength gradually decreases as the tempering time and temperature increase.While yield strength has a tend that increasing at shorter tempering times and decreasing at longer tempering times. It is well known that the quenching specimens shows a high dislocation density and as well as the hot-stamped specimens[6], while the lower dislocation density, together with the presence of nano-carbides, distinguishes the tempered specimens. The annihilation of dislocations during tempering treatment has been indicated by Gorynin et al. [7]. The increase of yield strength after tempering treatment can be related to the effect of carbide strengthening. The decreased effect of carbide strengthening at long tempering times can be related to the growth of carbides based on the "Ostwald ripening" mechanism[8] which decreases the contribution of carbide strengthening. The low yield strength/tensile strength ratio expresses the capacity of modern high-strength steels' grades to give a reliable behavior in service[9]. As seen in Figure 6 (b), when the tempered temperature at 250 ℃ the yield strength/tensile strength ratio is at a lower level. When holding times are at 5~30 min, the yield strength/tensile strength ratio increases while the yield strength/tensile strength ratio decreases when holding times are at 30~60 min. The product of tensile strength and elongation represents the overall mechanical properties of steel. As seen in Figure 6 (c), the product of tensile strength and elongation is at a high level. Compered with Figure 6 (b) and Figure 6 (c), it is found that the condition of temperature 250 ℃ and holding time 45 min can achieve the best comprehensive mechanical properties.

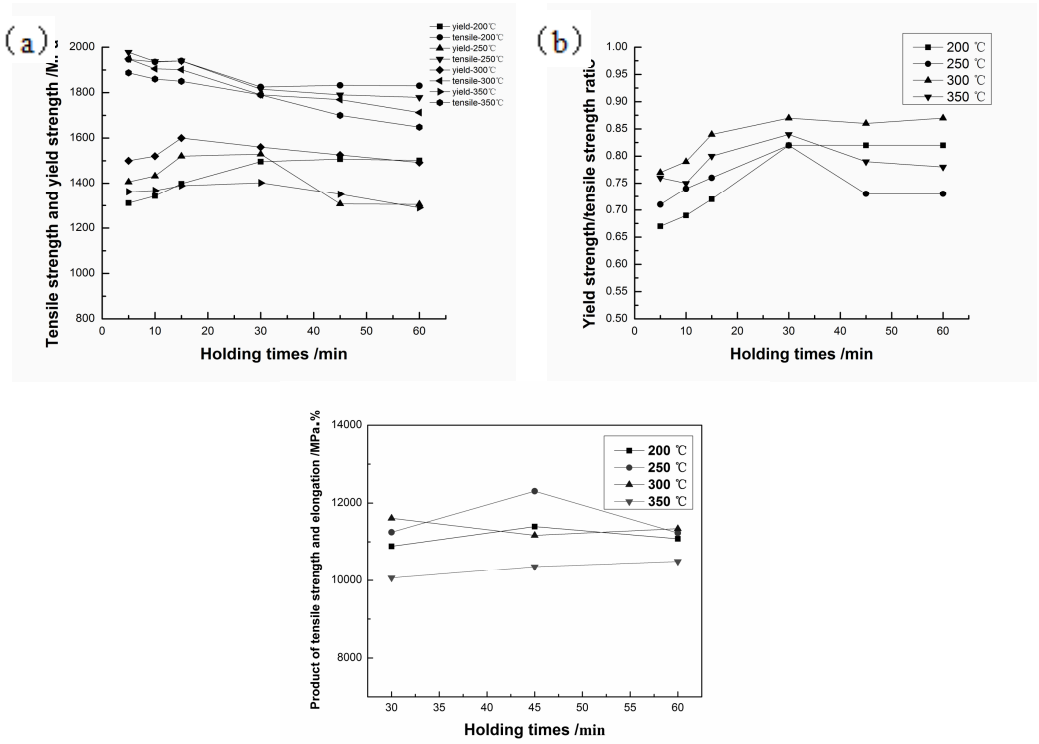

Fig.6 Mechanical properties of the studied steel after hot-stamped and tempered at different temperatures and times.

Summary

Non-isothermal resistance heating in the hot stamping of quenchable steel sheets was developed in order to form ultra-high strength steel products with tailored properties. The formed products can be obtained easily by changing the width of steel sheets and additionally mechanical properties of these products changed slowly and flexibly. The products with tensile strength from 600 MPa to 1800 MPa and elongation from 5 % to 18 % are formed. And mechanical properties can be changed with engineers' intention and special needs.

Hot stamping and tempering process makes it possible that significantly increase the ductility of hot stamping sample without decreasing the tensile strength greatly. By analyzing the different conditions that tempering temperature and holding time on the microstructure and properties of the sample it can be found that the condition of temperature 250 ℃ and holding time 45 min can achieve the best comprehensive mechanical properties.

Comparisons of Explicit and Implicit Finite Element Methods for Sheet Metal Forming

Lei Chen[1, a]

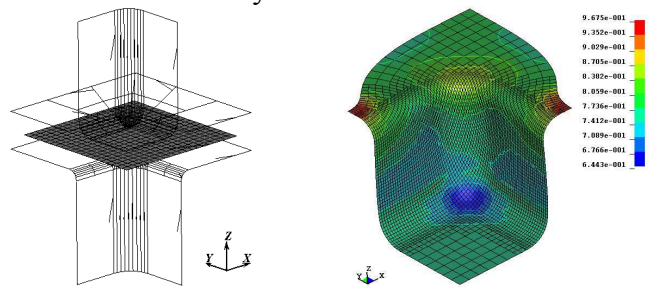
[1] Institute of Mechanical Engineering, Hangzhou Dianzi University, 310018, China

[a]ujs_cl@qq.com

Keywords: sheet metal forming, finite element method, simulation, comparison

Abstract: Sheet metal forming is one of the most commonly practiced fabrication processes in industry. Numerical simulations of the complex parts are possible by finite element method in the past thirty years. The most important problem of the simulation is the reliability of the model. Static implicit method (SI) and dynamic explicit method (DE) were used to simulation sheet metal forming process. It was found that simulation speed in dynamic explicit software has large effect on the simulation results. The best simulation speed is 5~10 m/s. Compared with the simulation and experimental results of thickness, draw-in and CPU time, the DE method is preferred.

Introduction



Sheet metal forming is one of the most commonly practiced fabrication processes in industry. Throughout the years, the sheet metal forming industry experienced technological advances that allowed the production of complex parts. However, the advances in die design and fabrication progressed at a much slower rate, and they still depend heavily on trial-and-error and the experiences of skilled workers.

With the development of the mechanical theory, finite element method and computer science, numerical simulation of sheet metal forming have been developed. It allows an early assessment of the part during the design stage, and enables a reduction in the product development time. Numerical simulations of the complex parts are possible by finite element method in the past thirty years. The most important problem of the simulation is the reliability of the model. An inappropriate model can lead to the long computer time and wrong results. There are at least two approaches available to model the sheet forming process. One is static implicit method (SI) and the other is dynamic explicit method (DE). Narkeeran et al. [1] utilized the explicit method to analyze the contact based forming operation of a production stamping process, and then an implicit solution was performed to simulate the springback that develops in a blank after the forming pressure has been removed. Ls-dyna3D and Pamstamp is the typical dynamic explicit software to simulate the sheet metal forming. Silva [2] illustrates the utilization of a dynamic explicit finite element computer program (PAM-STAMP) for evaluating the consequences of possible changes in process parameters and for debugging the causes of undesirable manufacturing occurrences. Firat [3] demonstrated in the stretch drawing process simulation using the Ls-Dyna finite element analysis code. Qiu [4] finishes the simulation of an engine hood panel's forming process with eta/DYNAFORM. Marc, Autoform and Abaqus/Implcit are the typical static implicit software. Taylor [5] used Abaqus to simulation the sheet metal forming. Kubli [6] optimized of sheet metal forming processes using the special purpose program AUTOFORM. Nguyen [7] described an inverse approach (IA) formulation for the analysis of tubes under free hydroforming conditions using the Marc finite element code. In this paper, the Numisheet 93 square benchmark problem was used to analyze the difference between the dynamic software Lsdyna and implicit software Marc. The simulation results were compared with the experiments.

Finite Element Model

Fig.1 shows the finite element model and simulation result. The blank thickness is 0.78 mm. the friction coefficient is 0.144. The blank holding force is 19.6KN. The plastic behavior of the sheet

material was modeled using a power law relation ($\sigma = K(\varepsilon_0 + \varepsilon)^n$), where σ is stress, K is material strength coefficient, ε_0 is initial strain, ε is strain, n is strain hardening coefficient. The material parameters are shown in Table1. The Barlat yield criterion was used.

90°			2.27	

Results and Discussion

Simulation speed in dynamic explicit software has large effect on the simulation results. So the simulation speed must be optimized firstly. Fig.2 shows the CPU time needed for different simulation speeds (1~100m/s). From the Fig.2, we can arrive that the CPU time decreases quickly with the increase of the simulation speed. When the simulation speed is more than 20 m/s, the CPU time is nearly steady.

Fig.3 shows the blank thickness with the different simulation speeds. From Fig.3, we can see that the largest and smallest thickness of the blank are nearly invariable with the speed of 1~10 m/s, and when the speed is larger than 10 m/s, the largest thickness decrease slowly and the smallest thickness decrease quickly. So the simulation results is unbelievably.

Fig.4 defines the draw-in length of the blank. Fig.5 shows the comparison of the simulation results and experimental results [8]. From Fig.5, we can see that the variations of the simulation results are very small with the simulation speed of 1~10m/s. When the simulation speed is larger than 20 m/s, the simulation results vary largely. Fig.6 shows the punch force with different simulation speeds. From the Fig.6, we can see that the punch force turn fluctuately largely with the increase of the simulation speed. Comparing with the experimental results, the best simulation speed is 5~10 m/s.

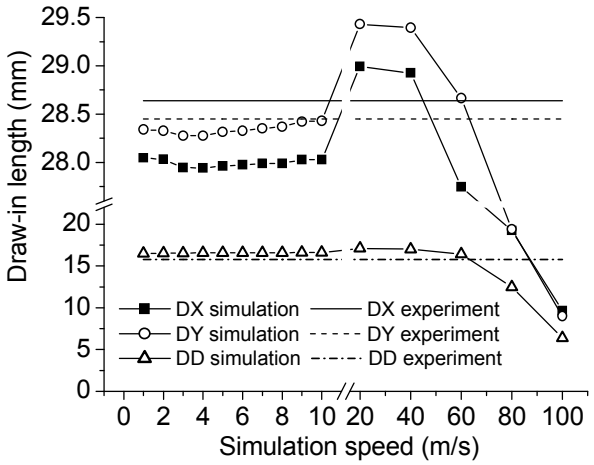

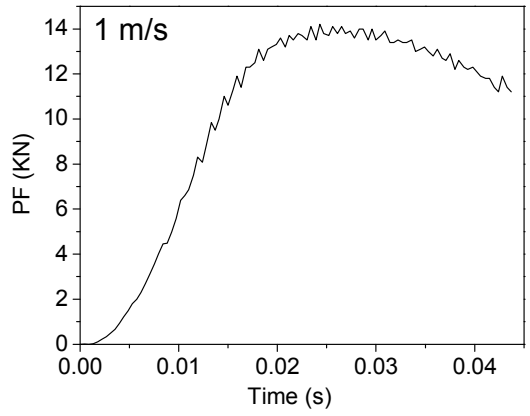

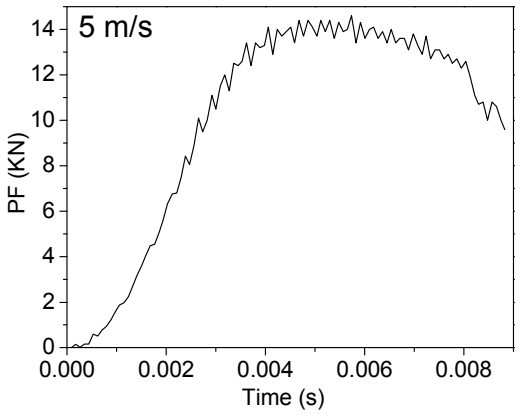

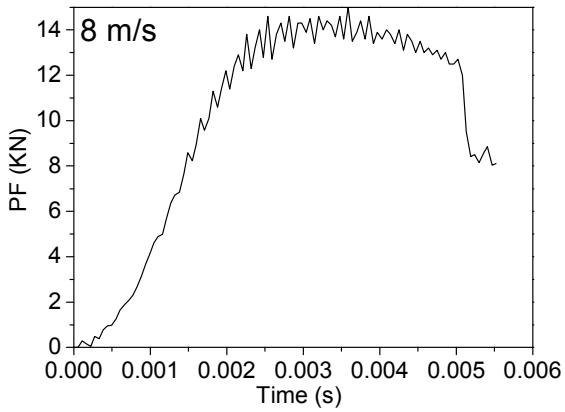

Fig.5 Draw-in length of flange with different simulation speeds

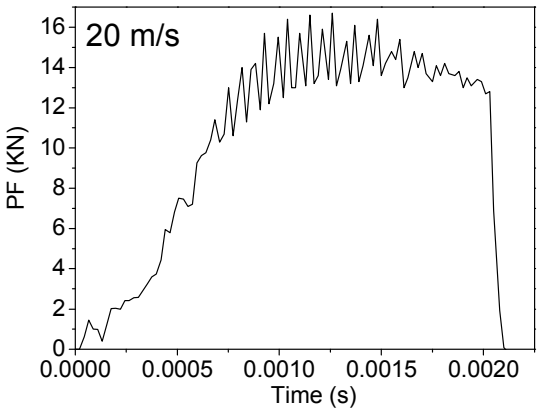

(a)

(b)

(c)

(d)

Fig.6 Punch force versus different simulation speeds

Table 2 shows the simulation results using different methods. The simulation speed in dynamic explicit method is 5 m/s. From the table, we can see that the Max thickness of SI is larger than that of DE, whilst the min thickness of SI is smaller than that of DE. The draw-in of SI is smaller than that of DE. The CPU time of SI is ten times of that of DE. Compared with the experimental and simulation results , the DE method is preferred.

Summary

Static implicit method (SI) and dynamic explicit method (DE) were used to simulation sheet metal forming process. It was found that simulation speed in dynamic explicit software has large effect on the simulation results. The best simulation speed is 5~10 m/s. Compared with the simulation and experimental results of thickness, draw-in and CPU time, the DE method is preferred.

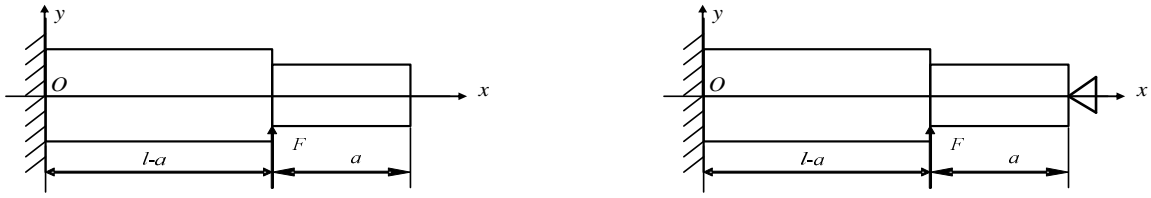
Keyword: Turning Work-piece; Bending Vibration; Model; Turning Depth; Numerical Simulation

Abstract: The mechanical models with and without thimble constraints for the turning work-piece are built respectively, applying ABAQUS software to analyze the modes of work-piece, then the law of the influence that different turning depth on the bending modes of work-piece is obtained. The study indicates that each-order natural frequency increase gradually in linear form for the work-piece without thimble constraint, while for the work-piece with thimble constraint, the natural frequency of the first four orders decrease linearly with the increase in the turning depth, but the change of high order frequency is relatively complicated.



Introduction

The effects of the dynamic characteristics especially the vibration characteristics of the work-piece and the cutting tool on the quality of products in the turning process are more and more concerned. Structural vibration characteristic analysis involves modal analysis, transient dynamic analysis, harmonic response and random spectrum analysis and so on. Modal analysis of structure is the basic of all structure vibrations analysis; it mainly studies the natural frequency and vibration mode of the structure. Modal analysis is the process to get the modal parameters and the parameters can be gained by calculation or experimental analysis [1-2]. The turning process of work-piece is time-variation and nonlinear [3]. At present, many basic researches have been studied; they are mainly about the deformation and vibration of work-piece [4-5], the vibration and wear of cutting tool [6-7], theoretical analysis and experimental test of dynamic characteristics [8]. When we analyze the modal of the work-piece in turning process, it is convenient to grasp the main modal characteristics of the work-piece in the easily effected frequency range at any processing time; it can also provide important reference for dynamic processing design of work-piece and diagnosis of vibration problem in manufacturing process. This article is based on the finite element calculation method, it studies the rule that how the turning depth influence the bending vibration model of the work-piece in the turning process.

Mechanical Model of Turning Work-piece

The work-piece can be simplified to a stepped shaft in turning process, seen as Fig. 1, turn short axis without thimble constraints; when turn long axis, there is thimble constraints on the right side.

As the turning tool moves, the location of the cutting force *F* and length *a* of the axis that has been cut will change along with time; with the material removals, the diameter and inertia moment of axis for the work-piece change with time piece-wisely.

(a) without thimble constraints (b) with thimble constraints

Fig. 1 Mechanical Model of Turning Work-piece

The free vibration equation of the work-piece is showed as follows

$$\frac{\partial^2}{\partial x^2}[EJ(x)\frac{\partial^2 w(x,t)}{\partial x^2}]+m(x)\frac{\partial^2 w(x,t)}{\partial t^2}=0 \quad (1)$$

Among them, $J(x)$ is the moment of inertia of axis on any section of the work-piece, m(x) is the weight of per unit length of the work-piece, $w(x,t)$ is the deflection on section x at time t.

Formula (1) is a time-varying differential equation, it's very difficult to seek out the modal analysis solution of the time-dependent dynamics in a variable boundary by analytical method, we will apply ABAQUS software which is based on finite element method to work out numerical solution.

Numerical Calculation Scheme and Finite Element Model

Set the calculating scheme of the short axis as following:

Select the parameters of the axis as following: Length l=100mm , diameter d=40mm , density ρ=7.8×10^{3}kg/m^3 ,turning speed n=600rpm, calculate the natural frequency and the vibration mode of the work-piece when the turning depth e=0.0, 0.5, 1.0, 1.5, 2.0 and 2.5mm ,respectively ,and the turning length a=50.0mm.

Set the calculating scheme of the long axis as following:

Select the parameters of the axis as following: Length l=600mm , diameter d=30mm,density ρ=7.8×10^{3}kg/m^3 ,turning speed n=600rpm , calculate the natural frequency and the vibration mode of the work-piece when turning depth e=0.0, 0.5, 1.0, 1.5, 2.0 and 2.5mm ,respectively, and the turning length a=300.0mm.

The numerical simulation is conducted by using software ABAQUS ，a large-deformation theory for static analysis is presented , the modal parameters are gained by linear perturbation analysis method , the element birth and death is used to realize the material failure in turning process. Short axis uses solid model, select C3D4 first-order tetrahedral element to mesh it; long axis uses beam element modeling, select BEAM31 to mesh it, Figure 2 is the corresponding finite element mesh figure of Figure 1.

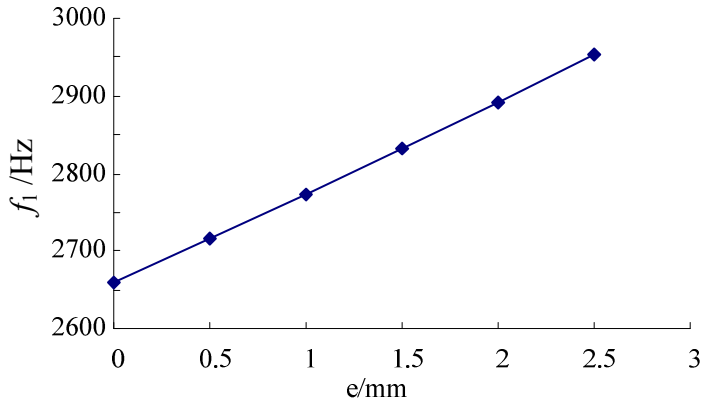
Figure 3 shows the first and the second order bending vibration model of the work-piece when we select the parameters: turning speed n=600rmp, turning depth e=1.5mm, turning length a=50.0mm; table 1 shows the natural frequency f of the work-piece with different turning depth e; figure 4 shows the change curve that the first order natural frequency f_1 of the work-piece change along with turning depth e in turning process.

(a)First order (b) Second order

Fig. 3 The first and the second order vibration mode of the work-piece at e=1.5mm

TABLE 1 BENDING NATURAL FREQUENCY F OF THE WORK-PIECE WITH DIFFERENT TURNING DEPTH

Natural Frequency	Turning Depth [e/mm]					
[f/Hz]	0	0.5	1.0	1.5	2.0	2.5
1st order	2658.4	2716.5	2773.2	2832.5	2892.9	2953.7
2nd order	2658.7	2716.7	2773.4	2832.8	2893.0	2954.3



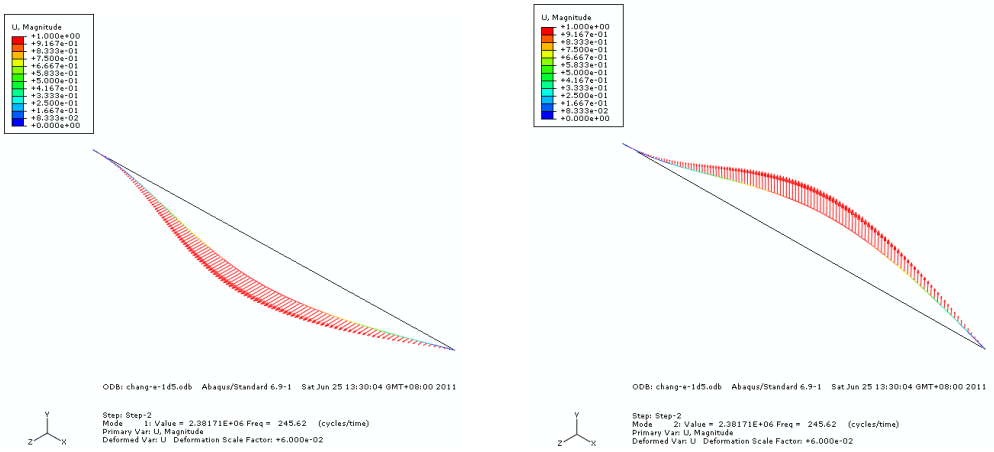


Fig. 4 Change Curve of the First-order Frequency with the Turning Depth e

According to figure 4, we know w that with the turning depth *e* increasing in turning process, each-order natural frequency *f* of the work-piece increases gradually in linear form.

The Simulation Result of the Long Axis

Figure 5 shows the first and the second order bending vibration model of the work-piece when we select the parameters: turning speed n=600rmp, turning depth e=1.5mm, turning length a=300.0mm; table 2 shows the natural frequency f of the work-piece with different turning depth e. Figure 6 shows the change curve that the first order natural frequency f_1 of the work-piece change along with turning depth e in turning process.

(a) First Order (b) Second Order

Fig. 5 The First and Second Order Vibration Mode of the Long Axis at e=1.5mm

TABLE 2 NATURAL FREQUENCY *F* OF LONG AXIS WITH DIFFERENT TURNING DEPTH *E*

Natural Frequency	Turning Depth [*e*/mm]					
[*f*/Hz]	0	0.5	1.0	1.5	2.0	2.5
1st order	256.86	253.41	249.65	245.62	241.36	236.93
2nd order	256.86	253.41	249.65	245.62	241.36	236.93

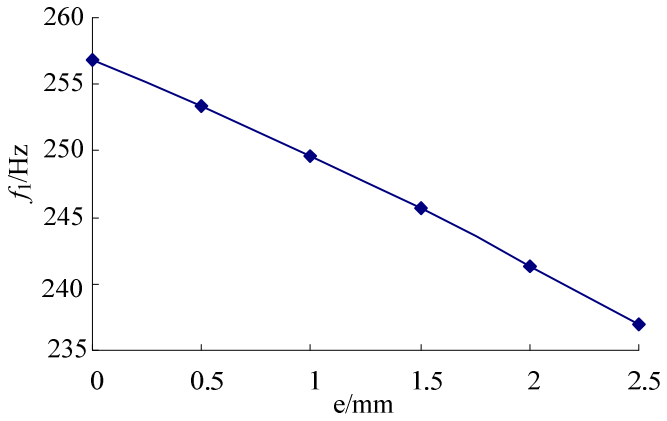

Fig. 6 Change Curve of First-order Natural Frequency f_1 with Different Turning Depth of the Long Axis

According to table 2 we know that with the turning depth e increases in turning process, the first-four-order natural frequency f of the work-piece decreases gradually mainly in linear form ,but the change of high order frequency is relatively complicated, for example the five order natural frequency increases constantly but the sixth order natural frequency decrease constantly. This

mainly because, as the turning depth e increases, the material of work-piece decreases, structure changes and integral rigidity decreases constantly, which cause the low-order natural frequency decreases. But the trend of high order natural frequency is relatively complicated due to the boundary condition and the effect based on nonlinear algorithm.

Conclusions

Mechanical model is built based on turning work-piece with and without thimble constraint , the law of the influence that turning depth of the work-piece on bending modes is studied by using the software ABAQUS to conduct numerical simulation , then we get the low order natural frequency and the vibration curve of the work-piece. Research shows that as the turning depth increases, each-order natural frequency increases gradually in linear form without thimble constraints, while for the work-piece with the thimble constraint, the first four-order natural frequency decreases in linear form, but the higher order frequency are relatively complicated.

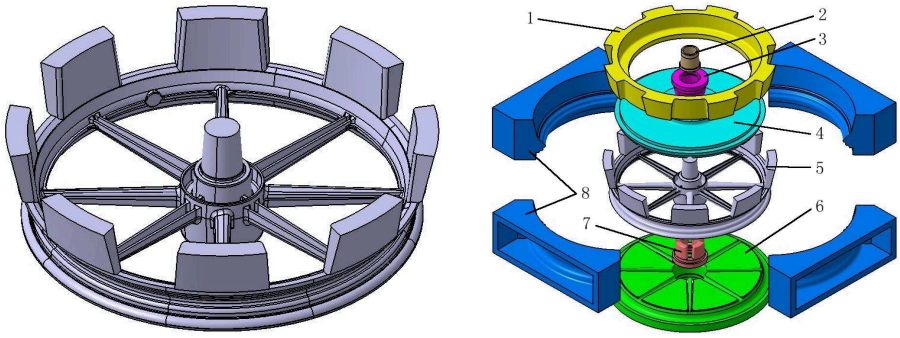
Keywords: multidisciplinary design optimization; casting process optimization; iSIGHT; ProCAST

Abstract. Casting process optimization usually includes modifying the mold structure, regulating the pouring temperature, changing pouring time, etc., which involves the mold structure optimization, but also involves optimization of temperature field. In order to get a better process conditions, it will generally make multiple simulation test under the different processes conditions. Many parameters should be set in each simulation test. In order to make casting engineers get liberation from a lot of repetitive work, multidisciplinary design optimization technology is firstly brought into the field of casting, successfully achieved ProCAST integrated into iSIGHT. The method of sample points collected is used in Optimal Latin Hypercube Design, and the building of approximation models is based on Kriging Model. On this basis, the optimization of the objective function is applied to Multi-Island Genetic Algorithm to obtain a global optimal solution. Compared to the verification result of the corresponding simulation, the relative error of the global optimal solution is 0.47%. The result of optimization is ensure average shrinkage rate of casting a smaller value when technological yield of the casting from 54.6% of the existing production case up to 61.1%.

Introduction



In recent years, the casting process simulation experiment is carried out in the optimization of casting process by a lot of technical personnel. ProCAST is one of the excellent casting process simulation software. The usual steps are: setting up 3D geometric model, grid generation, pre-processing to set parameters, calling the solver, post-processing to obtain the required results. If we want to get a better technological condition, a series of simulation experiment under different conditions are usually carried out. Because each simulation experiment will take a long calculation time, casting technician have to spend many days to constantly modify the geometry, meshing, setting simulation parameters and analyze and compare the results. The engineer usually find out the influence trend of the process parameters based on experience or using orthogonal experimental design and select the relative optimal combination as the process parameters process scheme, which rarely involves the use of optimization methods. Although a relatively good technology program is found out though the traditional optimization process, the optimization process does not guarantee the resulting solution is optimal. Therefore this optimization process, which is lengthy, inefficient, short of optimization method, is unsatisfactory.

Multidisciplinary Design Optimization (MDO) is a new method for engineering design, which takes full advantage of the respective strengths of each sub-discipline part, organize and manage the overall system design variables and optimization goals, finally allowing the system to get the global optimal solution. [1]

The current research about the multidisciplinary design optimization mainly concentrated in the field of aircraft design. [2-4] However, with the gradual development of multidisciplinary design optimization, workers in other fields have also done some research. [5-7] In the paper, we firstly introduce the method of multidisciplinary design optimization into the field of casting, successfully achieve ProCAST and the other software of casting process optimization integrated into iSIGHT. Here, taking casting process optimization of the wheel as an example, we specifically detail the method of multidisciplinary design optimization applied to the casting process optimization.

Optimization Model Building

The research object of this paper is the aluminum alloy wheel, using metal mold gravity casting, pouring way as the top-injection style, with eight risers uniformly distributed at the top position in the circumferential direction. The geometric model of the casting and molds are shown in **Fig. 1**.

(a) (b)

Fig. 1 (a) Casting of the aluminum alloy wheel; (b) Schematic diagram of casting and molds(1-riser mold, 2-gate mold,3-upper die core,4-upper die,5-casting,6-lower die,7-lower die core,8-side mold)

Design Variable

The three main parameters of the riser shape are selected as the design variables in this paper.

$$X=[\text{angle0}, \text{height0}, \text{width0}]^T. \quad (1)$$

Where angle0 is the inclination angle of the riser's side face respecting to the vertical plane, height0 is the riser height, width0 is the riser width. Each parameter is shown in **Fig. 2**.

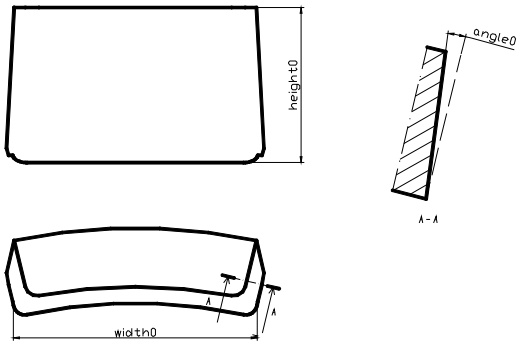


Fig. 2 Schematic diagram of the riser shape

The range of the three design variables about the riser shape are shown in table 1.

Table 1 The range of the design variables

design variables	lower limit	upper limit
angle0 [°]	3	9
height0 [mm]	55	75
width0 [mm]	90	110

Objective Function

There is no doubt that a good casting process is to make the casting shrinkage rate (f_1) as low as possible, at the same time to improve the casting process yield (f_2) as high as possible. Normally the two objectives are conflicting, that is, this is a multi-objective optimization problem. The multi-objective problem is transformed into a single objective problem through constructing a new objective function in this article. Define a new objective function as below,

$$y = w_1 \cdot f_1 + w_2 \cdot \frac{1}{f_2}. \tag{2}$$

Where, f_1 is the average shrinkage rate of the casting removal of the casting system and the riser, f_2 is the casting process yield, w_1 and w_2 are the weight coefficients of the two functions respectively.

According to the simulation result of the current process, it is found that the value of f_1 is about 0.01 and the value of f_2 is about 0.55. Due to the requirement of shrinkage rate is usually more important than the casting process yield, comprehensive considering w_1 =300, w_2=1.

Integration Process

Technological Process

Studied contents in this paper based on the software of iSIGHT integrated optimization platform, the integration process is shown in **Fig. 3**.

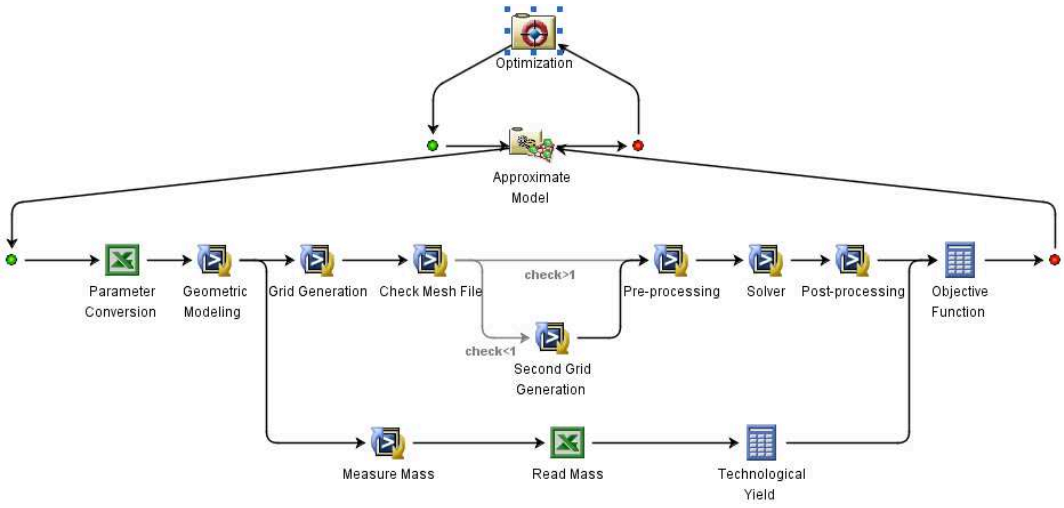

Fig. 3 Integration process

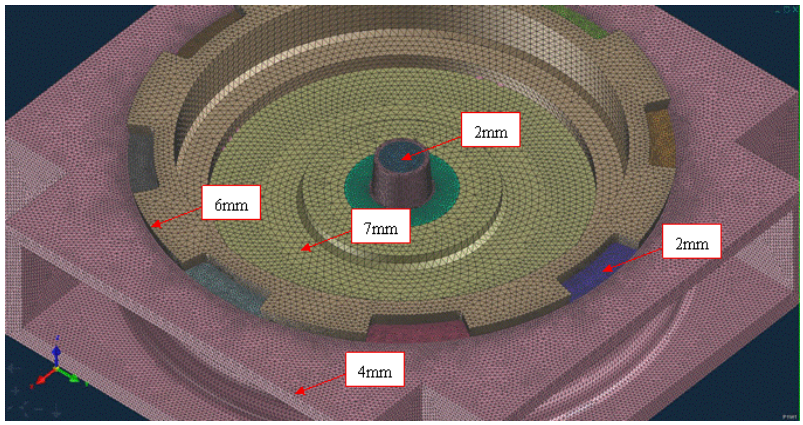
The first excel component "Parameter Conversion" shown in Figure 4 is the role of converting the three riser shape parameters angle0, height0, width0 data into CAD modeling process data. After the component "Geometric Modeling" completing, it is divided into two two processes simultaneously, one flow is meshing and generating the ProCAST simulation, then obtaining the average shrinkage rate of castings which excluding the part of the riser and gating system. The other flow is measuring the mass of the casting etc., then obtaining the casting process yield. Finally, the two processes get together, calculating the value of the objective function.

As the pre-processing of ProCAST software needs high quality tetrahedral mesh, thus to ensure the grid size of the thin-walled parts such as spokes is smaller enough, at the same time the grid size of the large surface on the die molds is bigger enough. While doing so, it reduces the number of the mesh model and decrease the computation time. Meshing model is shown in **Fig. 4**.



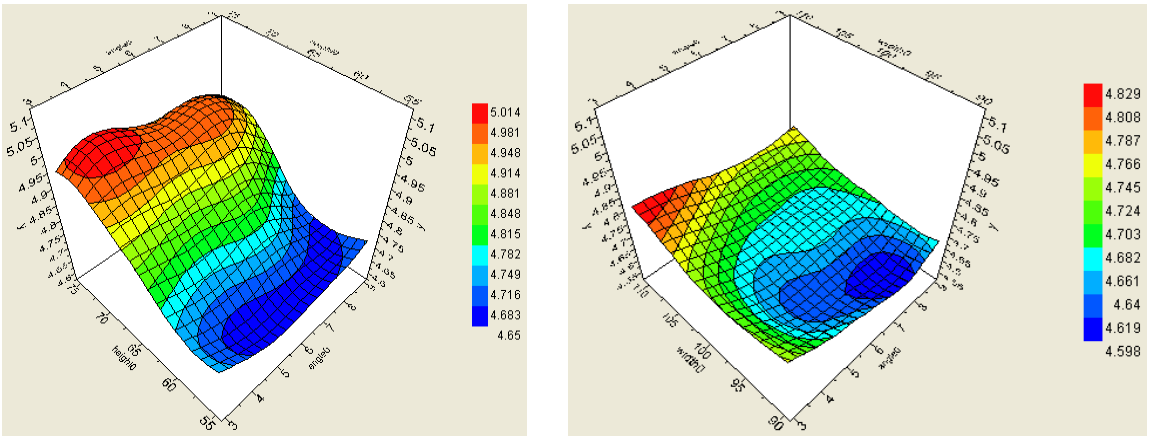


Fig. 4 Meshing model diagram

Building the Approximate Model

For engineering problems requiring casting process simulation, because of the time spent calculating the simulation experiment is usually very long. Therefore, the method of constructing the approximation model is considered in indirect optimization, it can reduce the computational cost and shorten the optimization time [8].

The approximate model is constructed by Kriging model in this article. Kriging Model which did not make any restrictions on the form of unknown function, can adaptively adjust the weights assigned each sample point. As Kriging Model take into account the spatial correlation of the regression error terms, the quality of approximate surface is very high [9].

The approximate model is based on the Optimal Latin hypercube design method in this article, finally it is concluded that the R-squared error value of the approximate model is 0.90721, of special note is on engineering, general requirement of R-squared is greater than 0.9. Therefore, the approximate model constructed in this article has a higher credibility. The approximate surface of angle0 and height0, angle0 and width0 on the value of an objective function diagram are shown in **Fig. 5(a)** and **Fig. 5(b)**, respectively.

(a) **(b)**

Fig. 5 (a) The approximate of angle0 and height0 to the objective function; (b) The approximate of angle0 and width0 to the objective function

Optimization Process

Optimization Methods

On the basis of the approximate model with the high credibility, we use a global optimization algorithm for optimization. There are many global optimization methods. Multi-island Genetic Algorithm (MIGA) is a improved optimization algorithm from the distribution of parallel genetic

algorithm, avoiding the easy premature phenomenon appeared in the traditional genetic algorithm. And MIGA algorithm is a pseudo-parallel genetic algorithm which can effectively improve the computational efficiency [10, 11]. Therefore, Multi-island Genetic Algorithm is employed in this paper. The sub-populations size is set to 10, the number of islands is set to 10, genetic crossover probability is set to 0.9.

Optimization Results

With the deepening of MIGA optimization process, after the end of the 2002 iterations, the last occurrence of "Feasibility=9" solution is the global optimal solution. The global optimal solution which corresponds to the design variables (angle0=7.3879°, height0=58.125mm, width0=91.681mm), achieve the objective function value (y=4.596) for the minimum. The objective function values of the optimization process are shown in **Fig. 6**. From the figure, it can be seen that the objective function value decreases rapidly at the beginning of the optimization, then the value gradually decreases to a minimum. The optimal solution is obtained after 1974 iterations of the optimization process.

Verification Results

In order to verify the optimization results obtained on the basis of the approximate model is accurate or not, The optimal solution (angle0=7.3879°, height0=58.125mm, width0=91.681mm) is used to make the casting process simulation experiment, the calculated value of the objective function is 4.6179. Compared to the objective function value of 4.596 which is the global optimal solution in the optimization process, the relative error is 0.47%, the accuracy of the optimization results is very high.

By means of casting process simulation for the optimal solution, when the critical porosity value is 5%, the distribution of the casting shrinkage porosity is shown in **Fig. 7**. The shrinkage porosity mainly concentrates in the gate and the riser, the shrinkage porosity of the wheel casting under the riser is almost non-existent. After optimization, the casting technological yield increases from 54.6% of the existing production case up to 61.1%, which obtains the good effect.

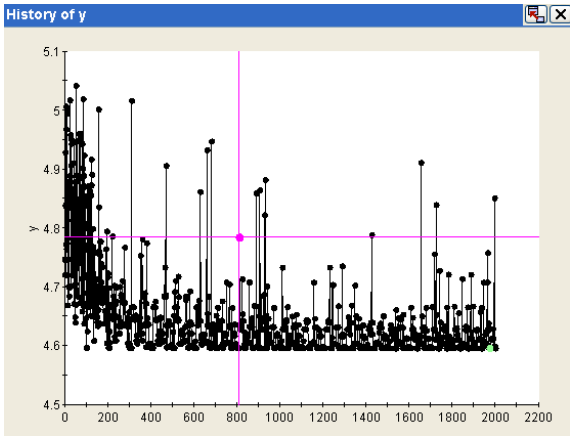

Fig. 6 The optimization process of value y

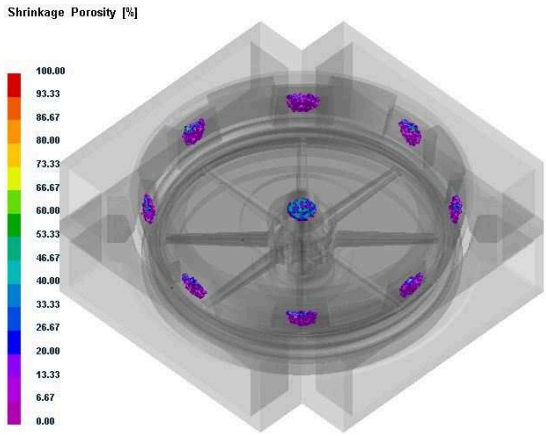

Fig. 7 Distribution of the porosity shrinkage

Summary

1. It is firstly to introduce the method of multidisciplinary design optimization into the field of casting, successfully achieve ProCAST and the other software of casting process optimization integrated into iSIGHT.

2. It realizes to optimize the casting process of the aluminum alloy wheels. Under ensuring the average shrinkage rate of the casting a smaller value, the casting technological yield increases from 54.6% of the existing production case up to 61.1%, which obtains the good effect.

3. Although it only optimize the riser shape of the wheel in this article, the application described in this article of multidisciplinary design optimization in the casting process optimization is not limited to this, such as further considering the pouring temperature, the pouring time, the cooling conditions, the riser shapes, the interfacial heat transfer conditions and the mold opening and closing time as the design variables, and further considering the casting technological yield, the average shrinkage rate of casting and the maximum stress value as objective functions. Therefore, the multidisciplinary design optimization techniques in the field of casting will have a more broad application prospects.

Abstract: The existing researches only put forward the stress concentration portion and design improvements from the perspective of stress analysis, or conducts safety assessment on dryers with the methodology of fracture mechanics, without non-destructive testing methods. Based on over 3,400 tests on cast iron dryers in Hangzhou, an ultrasonic testing technology with longitudinal wave double crystal probe is developed in the present investigation. This study illustrates how to identify the volume defects through testing on the air holes, shrinkage cavities and inclusions in the dryer cylinder and small R transition zone with longitudinal wave double crystal probe at a small angle (5°), as well as plane defects with deep cracks through testing on the dryer cylinder and small R transition zone with longitudinal wave double crystal probe at a large angle (42°). It addresses the issues of how to measure the thickness in regular online testing for cast iron dryers, to calculate the intensity or compare with the design value, to identify low hardness value, to determine the key parts in online testing, and how to conduct safety assessment on the cast iron dryers with small cracks. This technique may resolve various problems in cast iron dryer testing.

Introduction

Papermaking cast-iron drying cylinder is the very important component in equipment of papermaking. Since the cast-iron drying cylinder has thick wall, large heat capacity, good thermal insulation property, good abrasive resistance and low relative price, it is common to adopt gray drying cylinder for papermaking drying cylinder, such as HT200, HT250 and HT300, etc. The diameters of the cast-iron drying cylinder are generally 1.0m, 1.5m, 1.8m, 2.5m and 3m, etc, and it is over 4m at the maximum; The designed pressures of cast-iron drying cylinder are generally 0.3MPa, 0.5MPa, and even 0.8MPa; The media are mainly saturated steam or superheated steam and they are used to heat the cast-iron drying cylinder in order to dry the paper tasted in the surface of drying cylinder closely. The gray cast iron of cast-iron drying cylinder belongs to brittle material, and therefore, cast iron is easy to have casting defects in the process of casting. Every place in the whole casting structure may have potential dangerous defects. The inner casting structure is loose, the crystal grain is coarse and it contains a large amount of flake graphites inside, therefore the detection technology has great difficulties and there are very few researches on testing cast-iron drying cylinder in terms of internal defects of cast iron. The experimental research on testing specimen of papermaking cast-iron drying cylinder may use ultrasonic non-destructive testing. The common specifications of cast-iron drying cylinder are 1000mm, 1500mm, 1800mm and 2500mm and 4000mm at the maximum. Cast-iron drying cylinder is different from general structure of steel

pressure vessel. Cylinder block and cylinder cover are connected by bolt and discontinuous area in structure of cylinder block (for example, transition region of cylinder block) is the weakest part in drying cylinder.

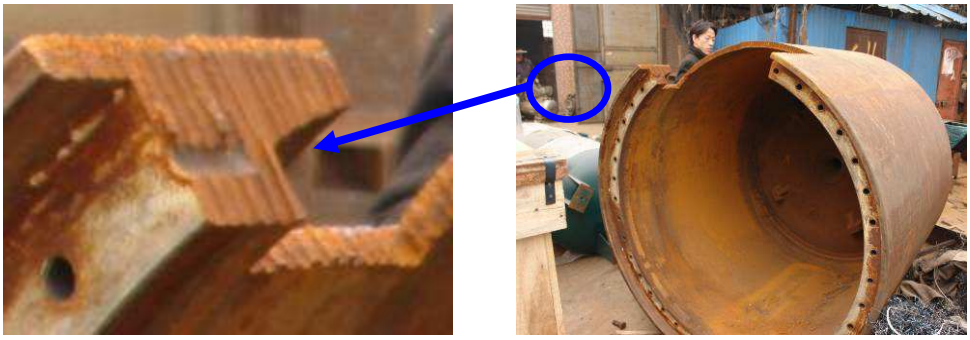

Fig 1 Dryer Cylinder's Internal Structure and Discrete Structure

The characters of ultrasonic testing of papermaking cast-iron drying cylinder

Bad air permeability of papermaking cast-iron drying cylinder

The features of casting of papermaking drying cylinder are that crystal grain is coarse and structure is not tight and even, and permeability to ultrasound is bad. In the process of casting, the cooling speed in each part of casting is different and it leads to the uneven microstructure. Generally, the diewall cools rapidly and has a large amount of solid nuclear particles, and the crystal grain of diewall is fine. When temperature of diewall increases, the cooling speed will be reduced and then it forms column zone in the direction of vertical diewall. When temperature of diewall increases further, the temperature of molten metal decreases, differences in temperature reduces, cooling speed is slown down and the directivity of crystal grain disappears, hence, equi-axed zone forms.

Bad acoustic coupling of papermaking cast-iron drying cylinder

The surface of casting of papermaking drying cylinder is coarse, the acoustic coupling is bad, the flaw sensitivity reduces, the beam directional characteristic is not good and probe wears seriously.

Much interference noise for ultrasonic testing of papermaking cast-iron drying cylinder

There are a lot of interference noises of ultrasonic testing of papermaking cast-iron drying cylinder. Firstly, it is due to that the stray reflection led by uneven property of the coarse crystal grain and structure forms grass echo. As a result, SNR decreases, especially in high frequency. Secondly, it is attributed that the shapes of castings are complex and there are a lot of signals without defect that are led by some outline echos and late strain waves. Besides, the coarse surface of casting will also create some reflection echo to interfere the correct judgment of flaw wave. The thickness of flange of papermaking drying cylinder changes from 20mm to 150mm and inner surface is sloped, therefore, there is no bottom surface to reflect echo in ultrasonic testing. The property of papermaking cast-iron drying cylinder is the reason why it can not be tested by current normal ultrasonic testing.

The block research of online ultrasonic testing of papermaking cast-iron drying cylinder

This is tested by using reflection longitudinal by longitudinal double crystal probe. In the same frequency, the attenuation coefficient is relatively smaller than s-wave, which is favorable for the testing of castings with coarse crystal grain. The detector can be divided into detector with small angle and detector with wide angle according to the angle of wafer. The material of block is gray

cast iron and the ultrasonic attenuation coefficient should be the same as or similar to the attenuation coefficient of tested cast iron drying cylinder. The defect of flat-bottomed hole more than or less thanΦ2 is not allowed to exist. Furthermore, it requires: ① roughness of test surface: the surface of casting Ra≤12.5μm and the surface of mechanical processing Ra≤10μm; ② it has no dirt affecting ultrasonic testing in test surface; ③ coupling agent: coupling agent with high viscosity can be selected, for example, grease, blending agent of machine oil and grease and paste etc.

5 Φ3mm flat-bottom holes, every hole is 25mm apart and the 5 holes are located in the middle of block with width of 50mm. And the distances of 5 flat-bottom holes with 3mm from test surface are respectively 5mm, 10mm, 15mm, 20mm and 25mm.

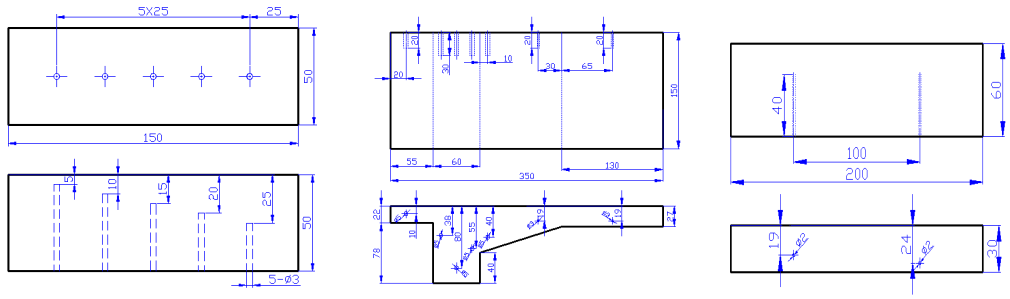

Fig 2 Long Cross-hole Reference

Drill Φ3 long cross-drilled hole at 10mm and 20mm of barrel of drying cylinder and drill four Φ5 long cross-drilled holes at 38mm, 40mm, 55mm and 80mm of small R part. Drill two Φ2×40 long cross-drilled holes at 19mm and 24mm of block with long cross-drilled hole. Make 2 blocks and 30mm length of grooving with depth of 2mm, 4mm, 6mm and 8mm in barrel and small R part respectively.

The online ultrasonic testing of papermaking cast-iron drying cylinder

Testing instrument and probe

The testing instrument is HS616e; the probe is 2.5MHz Φ20mm normal probe which is the specific probe; 1.5MHz longitudinal double crystal normal probe, 1.5MHz longitudinal double crystal probe with small angle and 1.25MHz longitudinal double crystal probe with wide angle.

Testing of permeability to ultrasound

Ultrasonic longitudinal wave is incident vertically on testing surface and non-defective cast-iron materials parallel to its back and the tested difference of wave height of B1 and B2 via longitudinal normal probe is showed by dB. In the area with the same cast-iron thickness, the average value should be obtained at least through testing three points.

Test actually block of long cross-drilled hole and that the difference of wave height of comparing blocks B1 and B2 of drying cylinder with long cross-drilled hole by 2.5MHz Φ20mm normal probe. It can not be tested by the secondary wave but by the primary wave.

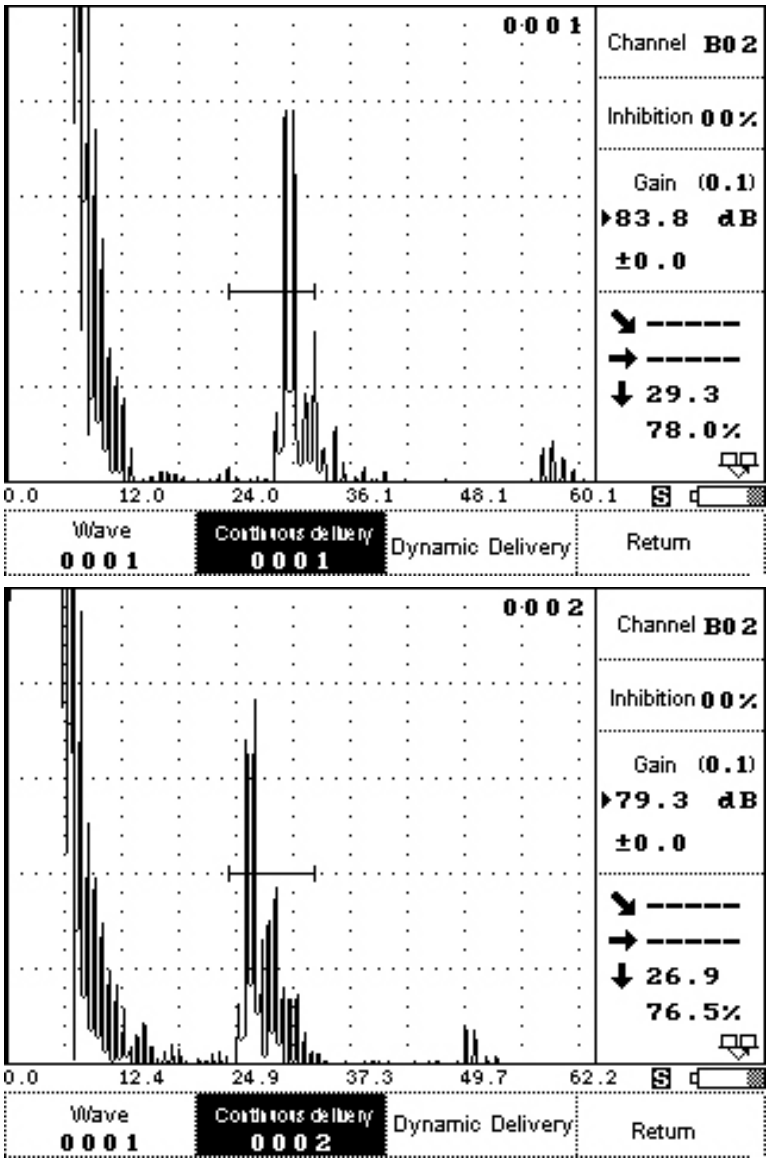

Fig 3 A Wave Detection Test Block Dryer

The sensitivity testing of various probes and comparative analysis of test results

Test flat-bottom hole in 25mm depth of block which is used by ZGZ series of double crystal probe through 2.5MHz Φ20 longitudinal normal probe. Because the frequency is too high and clutter is excessive, the defect can not be distinguished clearly.

Test block of long cross-drilled hole and comparing block of long cross-drilled hole by 1.5MHz longitudinal double crystal normal probe. The sensitivity of bottom wave is obviously higher than that of 2.5MHz Φ20 longitudinal normal probe.

Test flat-bottom hole in 25mm depth of block which is used by ZGZ series of double crystal probe through 1.5MHz longitudinal double crystal normal probe. It is also because the clutter is excessively high, the defect can not be distinguished clearly.

Test flat-bottom hole in 25mm and 20mm depth of block which is used by ZGZ series of double crystal probe through 1.5MHz longitudinal double crystal probe with a small angle, it can be distinguished clearly.

Make DAC curve in standard block of long cross-drilled hole by 1.5MHz longitudinal double crystal probe with a small angle.

Test comparing block of drying cylinder with long cross-drilled hole by 1.5MHz longitudinal double crystal probe with a small angle and the Φ3×25 long cross-drilled hole with 19mm depth can

be distinguished clearly. Test comparing block of grooving drying cylinder by 1.25MHz longitudinal double crystal probe with a wide angle. The waveform of grooving in 4mm and 2mm depth of barrel is shown in Figure 8.

Test comparing block of grooving drying cylinder by 1.25MHz longitudinal double crystal probe with a wide angle.

The research result of online ultrasonic NDT technology of papermaking cast-iron drying cylinder

Regular test scheme of papermaking cast-iron drying cylinder

The cast-iron materials of papermaking cast-iron drying cylinder belong to brittle materials. There is no practical test scheme specific to cast-iron drying cylinder in new "*The Inspection Regulations of Safety Technology of Fixed Pressure Vessel*" (TSG R0004-2009) and in "Design Regulation of Cast-iron Drying C*ylinder Used by Papermaking Machine*" (Q/T2556－2002) and "*Technical Specifications of Cast-iron Drying Cylinder Used by Papermaking Machine*" (Q/T2551－2002), they are only specific to design and manufacturing of cast-iron drying cylinder used by papermaking machine.According to general investigation and research requirement of inspection, the key test projects conducted in online regular test scheme of papermaking cast-iron drying cylinder include: review of original materials, macroexamination, geometry examination, measurement of wall thickness, surface inspection, hardness inspection, ultrasonic inspection, strength checking, pressure test and checking of safe accessories.

Ultrasonic testing method of papermaking cast-iron drying cylinder

According to the features of bad permeability to ultrasound, bad acoustic coupling, much interference noise of papermaking cast-iron drying cylinder, they can be solved via the following six measurements after experimental research:

In terms of bad permeability to ultrasound, it can be improved from detection instrument, probe and testing method. Ultrasonic detection instrument can be the instrument with big launching strength and high surplus sensitivity; the probe selects longitudinal double crystal probe with high sensitivity and they can make specific low-frequency probe. If it is low frequency, the wavelength is long and the ultrasonic penetrability is good as well. The testing method takes primary longitudinal wave method, because the longitudinal wave is of rapid speed and long length.

In terms of bad acoustic coupling, they can make grease with high paste or machine oil as coupling agent. In terms of a lot of interference noises, they can develop specific probe. The double crystal probe with different focal distances can make beam energy concentrate on the tested part, while the probe with a small angle is good to reduce interference noise so as to increase the rate of inspecting defect.

In terms of testing crack in small R part, they can take double crystal longitudinal probe with different focal distances and a wide angle to conduct primary wave test. Test air hole, shrinkage and inclusions of barrel and transaction of small R part through longitudinal double crystal probe with a small angle. Test crack of barrel and transaction of small R part through longitudinal double crystal probe with a wide angle.

The process of online testing defect of papermaking cast-iron drying cylinder

The reduction of wall thickness of papermaking cast-iron drying cylinder and surplus wall thickness are involved in the safety allowance, the reduction of hardness and strength should go through strength check on the basis of online checking. Papermaking cast-iron drying cylinder is

easy to loosen particles and enlarge shrinkage. According to the above defects, they should conduct strength intensity check for drying cylinder. Under this premise of ensuring strength calculation requirements and referring to manufacturing requirements of cast-iron drying cylinder, the surface defects can be repaired by thread plug, but the depth of plug can not be more than 40% of section depth, the diameter of plug can not be more than the depth of plug and widen it to less than 8mm: as for round defect of air hole and shrinkage etc, if the maximum diameter≤4.0mm and the depth is less than 40% of the section depth, they can not be handled; If the maximum diameter ≤10.0mm and the depth is less than 40% of the section depth, the diameter of plug is not more than 10mm, and the level of safety condition of drying cylinder by online regular test is level 3.

Drying cylinders with more air hole can be repaired in some conditions. But if repaired holes increase, the strength of drying cylinder will be weaken. Therefore, the total repaired holes in per square meter of active drying cylinder can not more than 10. It is not allowed to have cracks in the process of online testing of papermaking cast-iron drying cylinder. In case of crack, if it disappears after being polished, the intensity check is qualified and will not influence the normal classification. Otherwise, it is the level 5 of disqualification and must be scrap. As for the crack less than 2mm depth, It is hard to be found in online testing. This kind of crack is basically in the range of safety assessment via research and can be used safely.

Keywords: Diesel Engine; naïve Bayesian classifier; NO_x; one-dependence classifier

Abstract. Increasingly serious environmental pollution,trying to find a effective method to control NO_x emission become more importance. Under this background, this paper adopts the naïve Bayesian classifier method which built on the basis of the probability density function to forecasting the NOx emission of diesel engine. This paper proposes a new approach to weight the super-parent one dependence estimators, and uses the UCI datasets to verify the validity of the proposed method. Finally, apply this diagnosis technology to the collected WD615 diesel engine data. The comparison experiments with other algorithms demonstrate the effectiveness of the proposed method.

Introduction

Bayesian forecasting is established based on the probability density function. Compared to the others, it has smaller diagnostic error rates. So it has an extensive application. With the development of information and automation technology, a lot of running data and diagnostic data has been accumulated and it is possible to calculate the prior probabilities of Bayesian method. However, in many practical fields, the independency assumption of naïve Bayes (NB) does not hold. Therefore, many researches are mainly about how to use some technology to find a most favorable topology among all possible network structures. At present, such technologies can be summarized into two categories: heuristic search and correlation analysis. To relax the independency assumption, the researchers have done a lot of work. With the development of modern science technology and the degree of automation, diesel engine fault diagnostic technique has undergone significant changes and Bayesian diagnosis become one of the most efficient diagnosis methods.

Among all these improving approaches, Super-Parent One Dependence Estimators (SPODEs) [1] can be considered a subcategory of ODEs where all attributes depend on the same attribute. L.X. Jiang [2] et al adds the parent node for some attributes in Bayesian network using conditional mutual information. Aggregating One-Dependence Estimators (AODE) ensembles all SPODEs that satisfy a minimum support constraint[3] and estimate class conditional probabilities by averaging across them. This ensemble has demonstrated very high prediction accuracy with modest computational requirements. However, it is based on an implicit assumption that all SPODEs have the same or equivalent learning ability. But the leaning ability of different Bayesian networks is different. Simply averaging all SPODEs may scale up the influence of the bad performance classifiers so as to affect the final classification result. WAODE [4] is an improvement of AODE.

New Approach to Weight SPODE

SPODE

Super-Parent One Dependence Estimators (SPODEs) can be considered a subcategory of ODEs where all attributes depend on the same attribute. A SPODE requires all attributes to depend on the same attribute, namely the superparent, in addition to the class.

A data sample of n attributes can potentially have n SPODEs, each alternatively taking a different attributes as the super parent, as shown in Fig.1. In this paper, we consider the diversity of SPODE and its corresponding NB and propose a new approach to weight SPODE.

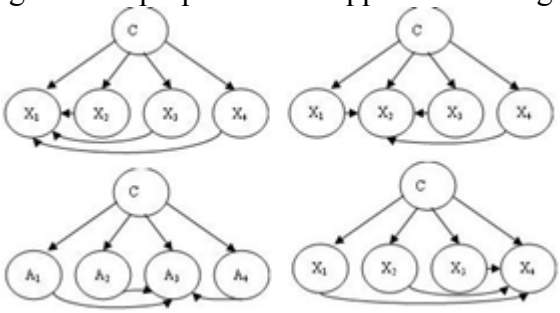

Fig.1 SPODEs with 4 Attributes

Diversity of SPODE and its Corresponding NB

A natural question is that how well a SPODE can perform in predictive tests. If the prediction result for a test instance by using a SPODE is same with that by using NB, we can say that the performance of the SPODE is not very well. We would rather use its corresponding NB than the SPODE since the structure of SPODE is more complex than simple NB and the parameter estimation needs more time while the performance are the same.

Definition 1 if a test instance X is classified to the same class by using SPODE and NB, we say the performance of SPODE and NB is equivalence.

Definition 2 Suppose there are m classes. Let *Diver* ($SPODE_{A_t}$, NB) be a m×m square array such that $Diver_{ij}$ is the number of test examples assigned to class c_j by $SPODE_{A_t}$ with and to class c_i by its corresponding NB. Let |Diver| be the number of all test examples. The diversity of $SPODE_{A_t}$ and its corresponding NB is defined as follows.

$$Diff(A_t) = \frac{1-\alpha}{1-\beta} \tag{1}$$

Where α be the probability that the $SPODE_{A_t}$ and its corresponding NB perform the same, β be the probability that the $SPODE_{A_t}$ and its corresponding NB agree by chance. They are respectively defined as follows.

$$\alpha = \frac{\sum_{i=j=1}^{m} Diver_{ij}}{|Diver|} \tag{2}$$

$$\beta = \sum_{i=1}^{m}(\sum_{j=1}^{m}\frac{Diver_{ij}}{|Diver|}\sum_{j=1}^{m}\frac{Diver_{ji}}{|Diver|}) \tag{3}$$

Further, we have the following discussion.

(1)When $Diff(A_t)$=0, we can get $\alpha=1$. It means that the classification results using $SPODE_{A_t}$ and its corresponding NB are completely same. The two classifiers agree on every example.

(2)When $Diff(A_t)$=1, we can get $\alpha=\beta$. It means that $SPODE_{A_t}$ and its corresponding NB equals that expected by chance.

(3)When $Diff(A_t)$>1, we can get $\alpha<\beta$. It means that agreement is weaker than expected by chance. In another words, the probability of the two classifiers obtain the same classification is little.

(4)If the diversity between the augmented naïve bayes and the simple naïve bayes is small, it has no need to expand the network structure of NB. Because the complexity of probability estimation is closely related to the network structure.

From the above discussion, we can get the conclusion that the diversity between the augmented naïve bayes $SPODE_{A_t}$ and the simple naïve bayes increases with the increase of the value of $Diff(A_t)$. Therefore, we take $Diff(A_t)$ as the weight of $SPODE_{A_t}$.

SPODEs Ensemble

According to the above discussion, firstly we give the definition of the weight of $SPODE_{A_t}$.

Definition 3 Let w_t represents the weight of $SPODE_{A_t}$. w_t is defines as:

$$\omega_t = \frac{Diff(A_t)}{\sum_{i=1}^{n} Diff(A_i)} (\sum_{i=1}^{n} Diff(A_i) \neq 0) \tag{4}$$

Where $Diff(A_t)$ is defined in (4) and $\sum_{t=1}^{n} \omega_t = 1$.

Since (4) holds for every SPODE, we can get our classifier as follows.

$$P(c \mid X) = \begin{cases} \dfrac{\sum_{t=1}^{n} \omega_t P(c, a_t) \prod_{j=1, j \neq t}^{n} P(a_j \mid c, a_t)}{P(X)}, \sum_{t=1}^{n} \omega_t \neq 0 \\ \dfrac{P(c) \prod_{j=1}^{n} P(a_j \mid c)}{P(X)}, else \end{cases} \tag{5}$$

The value of w_t can determine the number of SPODEs used as well as the the importance of every SPODE. For example, if $w_{t=0}$ and $w_j \neq 0 (j \in [1,n], j \neq t)$, we actually only select n-1 SPODEs. In a extreme case when $\sum_{i=1}^{n} Diff(A_i) = 0$, we will use NB to classify all test samples. But this kind of situation is rare. Because it means that all SPODE perform exactly the same with NB. Every SPODE and its corresponding NB agree on every example.

Experiments

Experimental Settings

(1) Test data

In this paper, we choose 16 UCI datasets (shown in table 1) and 3 foul diagnostic datasets of WD615 diesel engine (shown in table 2). All datasets are preprocessed with the help of WEKA software before using. Use the supervised filter Discretize in WEKA to discretize all the numeric attributes; Use the unsupervised filter Remove in WEKA to remove useless attributes.

(2) Validation method

10 runs of 10-folds CV test for comparing the classifier performances. Each datasets are divided into 10 almost equal-sized blocks randomly, and in each validation, one block was used for test data and the remaining blocks were used for training classifiers. Average all 10 runs as the final results.

(3) Measurement

Throughout all the tests, we measured the classification error rate, i.e., the percentage of incorrectly classified instances.

Error rate= number of incorrectly classified instances / the total number of instances of prediction.

(4) Comparison algorithms

This paper compares the proposed method with AODE，WAODE and LODE.

Experimental Results and Analysis

The experimental results are shown in table 3. Since the average error rates of different classifiers are very close. So we compare each two algorithms A-B via two tailed t-test with a 95 percent confidence level. The results are shown in table 5, where win indicates that algorithm A obtained significantly lower average error rate than algorithm B, draw indicates that A and B haven't significant differences, and loss indicates that A obtained significantly higher average error rate than algorithm B. From table 5, we can see that WSPODE outperforms AODE on 9 datasets, outperforms WAODE on 8 datasets, and outperforms LODE on 8 datasets.

Conclusions

The traditional naïve Bayesian diagnostic model is established under the strict independency assumption. On order to relax the assumption so as to gain smaller classification error rate, the study of one-dependence estimator is receiving more and more attention. This paper proposed a new strategy. It took advantage of the diversity of SPODE and its corresponding NB to weight the super-parent one dependence estimators. Through the comparison experiments with the existing AODE, WAODE and LODE, the results verified the effectiveness of the proposed algorithm.

Analysis of Grinding Roller Stress Distribution of Vertical Roller Mill

Xiaohong Jiang [a], Ping Ye [b], Zongkai Li [c]

College of Mechanical and Electrical Engineering, China University of Mining and Technology, Xu Zhou city, Jiang Su Province, P. R. China

[a]xh.jiang@126.com, [b]yp@cumt.edu.cn,[c]lizk@cumt.edu.cn

Keywords: Vertical roller mill, roller force, Compaction zone stree, Weibull distribution

Abstract: The quality of powder of non-metal materials directly relates to the force exerted on grinding roller, while the force on grinding roller relates to the thickness of the material layer. The uneven pressure distribution between the roller and material layer is caused by the drum-shaped characteristics of vertical mill grinding roller. This paper studies the pressure distribution of roller in compacted zones, established mathematical models of pressure distribution analysis, and provides a theoretical basis for improving the vertical mill production process as well as yield and quality of the powder.

Introduction

Vertical mill is suitable for middle and high hardness, brittle material crushing processing, mainly used in pharmaceutical, food, daily chemical and other industries and non-metallic mineral areas.

Analyzing the forces on the grinding rollers and the stress on the rolling compaction zone are the foundation for studying the vibration mechanism of the non-steady state of the vertical roller mill. From the published articles, the little research in this area of the vertical roller mill is not yet enough on research depth. This paper attempts to analyze theoretically the grinding roller force and the rolling compaction zone stress distribution, strive to describe the forces acting on grinding rollers and the stress distribution of the compaction zone more accurately, and draw relevant parameters, to provide a basis for follow-up study.

Roll crush is by a heavy grinding rollers rolling over the material layer, the role of static and dynamic pressure is to make the compaction materials layer obtain permanent residual deformation h, shown in Fig.1. As the number of rolling increased, the materials layer become denser, and the residual deformation are accordingly reduced, and finally the residual deformation h is equal to zero, and then the material are crushed[1,2].

During the vertical roller mill in working, the role of the external forces acting on the rollers include: the vertical force G (1/3 the weight of the grinding rollers framework of gravity plus hydraulic loading force); horizontal force T (the framework supporting force in the horizontal direction), as well as the reaction force from the material layer. The reaction force of material layer on the grinding rollers are divided into the vertical pressure N and the friction force F. It is the friction F that driving grinding rollers rotating, as shown in Fig. 1.

In the rolling compaction zone, the vertical component of the joint force of the pressure N and the friction force F balances with the vertical force G, and the horizontal component of the joint force, with the horizontal force from the pressure framework T. Friction F acting on grinding roller drive roller rotation, while the horizontal component of the friction acting on three grinding rollers, combining the horizontal component of the normal pressure N constitute a torque on pressure framework through the rollers, while the overall torque of the pressure framework is ultimately acting on the buffers.

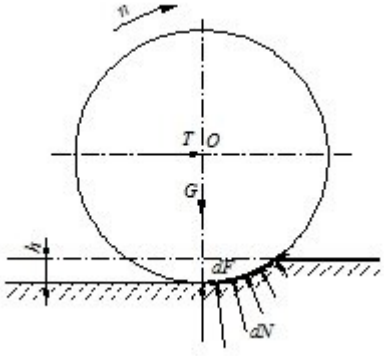
Be discussed later, it is this torque is one of the main reasons for the abnormal vibration of the mill.

Stress Analysis of The Rolling Compaction Zone Between the Roller and the Materials

The mill table rotates initiatively, the roller passive rolling. In the circle view direction of the grinding roller, the contact stress distribution between the roller and the material layer [3, 4], is shown in Fig.2.

Grinding rollers weight, the gravity of the pressure framework and hydraulic loading force are the active external forces, and due to the role of the horizontal component of the active external force T, the maximum compressive stress σ_{max} of material layer is not at the lowest point of grinding roller, but move to the feeding direction for some distance Δa. As pressed material has a certain viscosity, the deformation is often later than the stress changes, resulting in load aftereffect phenomenon, that is, when the stress reaches its maximum and began to decline, the material deformation will remain for some time [5].

Actually, load mainly acts on the first half contact arc between material layer and rollers, the compressive stress was non-symmetrical distribution, the total depth h of the roller indentation can be divided into two parts of elastic deformation h_a and plastic deformation h_H, namely, $h = h_a + h_H$.



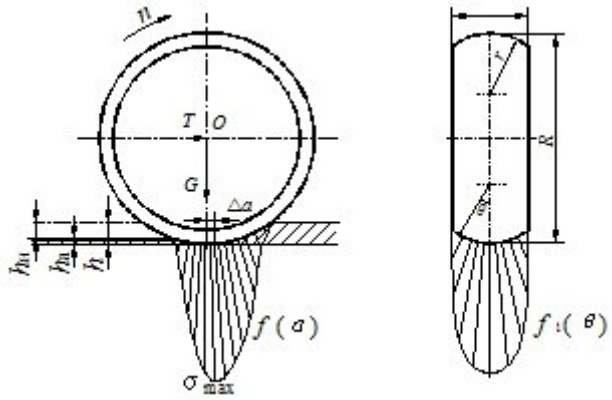


Fig. 1. The residual deformation of the materials layer

(a) The roller circle view direction (b) The roller width direction

Fig. 2. Rolling stress distribution

There had been some formulas to describe the stress distribution of wheel roller compacted material layer[3], such as, the relationship between the material pressure p and indentation depth h under the rigid wheel is expressed as:

$$p = kh^{\mu} \qquad (1)$$

Meanwhile, the outer edge of the roller is grinded more seriously than the inside edge by the materials.

k - material compression coefficient; μ - material condition factor, the range of 0～1.

Formula (1) is very simple, but there are limitations: It could not describe the stress condition on the vicinity of separation point of material away from the wheel; The formula (1) only able to apply to the rolling wheel of a cylinder shape.

The grinding roller in this paper is of a drum-shaped, so it is necessary to investigate the stress distribution from the circle view direction of the grinding roll, from the width view direction of the roller, as well as in three-dimensional rolling compaction region, to find out the normal pressure acting on the grinding roller, the expression of the vertical and the horizontal component of the normal pressure as well as related parameters.

The direction of the grinding roll circle view, district material layer stress distribution curve

To more accurately establish the pressure distribution model between the roller and the materials, according to the information and references provided by the manufacturer, the form of a three-parameter Weibull distribution curve is presented in this paper, to describe the stress distribution pattern from the circle view direction of the grinding roller [6,7].

Determining stress distribution curve form

$$f(\alpha)=\frac{\beta}{\eta}\left(\frac{\alpha-\gamma}{\eta}\right)^{\beta-1}\exp(-\left(\frac{\alpha-\gamma}{\eta}\right)^{\beta}) \quad (2)$$

Where β -shape parameters; γ - positional parameters; η - scale parameter.

Variable α is the central angle of the down the longitudinal axis of the grinding roller radius as starting line, clockwise negative, counterclockwise normal. Show in Fig. 3.

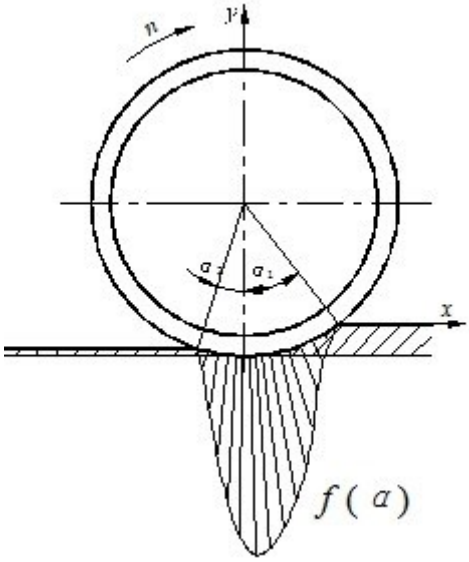

Figure 3 Central angle settings of roller stress zone

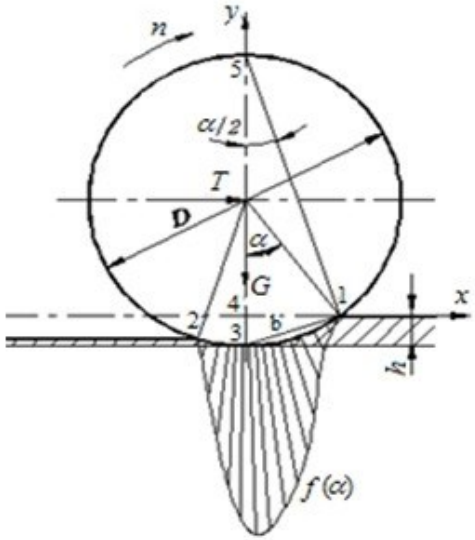

Figure 4 Relations between *b*, *d* and *h* in roller stress zone

Here are just using the probability density function $f(\alpha)$ to describe the distribution pattern of roll grinding stress. Weibull curve $f(\alpha)$ multiplied by an undetermined the constants C_1 to describe the actual stress.

Suppose materials entering the grinding roller from right to left, see Fig. 4, and the material moving from the feed point 1, through the lowest point 3 of grinding roller, and finally to the discharge point 2, to leave the grinding roller. It can be seen from the Fig. 4, that the arc length of grinding roller from the contact point 1 to the lowest point of the roller contains the material stress varied from zero to maximum process, set the chord length from point 1 to point 3 is *b*, the roller diameter is *D*, sag depth (distance between two points 3,4) is h, relationship between the three variables:

$$b=\sqrt{Dh} \quad (3)$$

According to the data given by the factory, the difference of material layer thickness between the material feed inlet of the mill roll and the roller lowest point, h = 42 mm. Roller diameter D = 2.8m, the circumferential angle (α_1/2)=arcsin*(h/b)*.

Central angle α_1 twice in the circumferential angle, equal to 0.2456 radians, is approximately 14.0718 °, from the point of contact of the roller and the material layer to about 14° central angle between the grinding rollers lowest point.

Given the central angle α corresponding with the chord length b, then

$$\frac{b/2}{D/2} = \sin(\frac{\alpha_1}{2}) \quad (4)$$

$$\text{or } \sqrt{\frac{h}{D}} = \sin(\frac{\alpha_1}{2}) \quad (5)$$

The indentation depth h is:

$$h = D\sin^2(\frac{\alpha_1}{2}) \quad (6)$$

It can be seen from equation (6): Once the roller diameter D is given, the deeper the sag, the greater the contact angle.

In the grinding process, the material layer thickness are constantly changing in the range of 80mm~130mm, the size of feeding material is also changing around 70mm, so is the contact angle α and the pressure area of material layer, resulting in the size and the location of the vertical and the horizontal component of the normal pressure changing, which make the torsional angle of the pressure framework change ceaselessly, forming the torsional vibration. Severe, the crash sound of pressure framework against the shell could be heard on-site.

Stress distribution curve parameters

Shape parameter β

The grinding process without elastic deformation of the material layer are described in Fig.1, the material layer height of the roller lowest point is the material thickness at the grinding roller export, that is h_a=0, location parameters γ=0. At this time, the stress distribution between the roller and the material layer can be described by the two-parameter Weibull distribution function:

$$f(\alpha) = \frac{\beta}{\eta}\left(\frac{\alpha}{\eta}\right)^{\beta-1}\exp(-\left(\frac{\alpha}{\eta}\right)^{\beta}) \quad (7)$$

Without loss of the generality and the simplicity, let the scale parameter η = 1, the interval of α among [0, 2.5], the Weibull curve is shown in Fig.5. It can be seen that the Weibull curve of the parameters β = 2 is more appropriate to describe the stress curve between the roller and the material layer.

Scale parameter

The scale parameter η affects the dispersion degree of curves along the abscissa axis. Fig.6 shows the β=2, γ= 0, the influence to the Weibull curve by the scale parameterη changing.

In order to make the starting point and end point of the stress distribution curve is consistent with the contact zone of the grinding roller and the materials, the arc length of the stress curve is needed to adjust, which mainly by modifying the scale parameter η values, and at the same time, location parameters γ also needs to make some adjustments. According to the data provided by the factory: the central angle α of the contact zone between material and roller is about 14 °, refer to fig.3. The central angle α_2 of the discharge interval typically is less than feeding interval angle α_1, α_2 equal approximately 1/3α_1~ 1/10α_1, take α_2 = 1/8 α_1, hence the angle interval is [-1.75°, 14°]

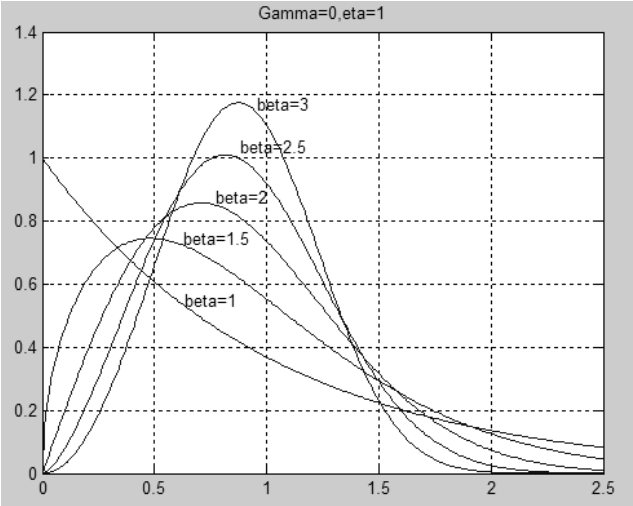

Fig. 5. Influence of shape parameter β on Weibull curve under certain parameters γ and η

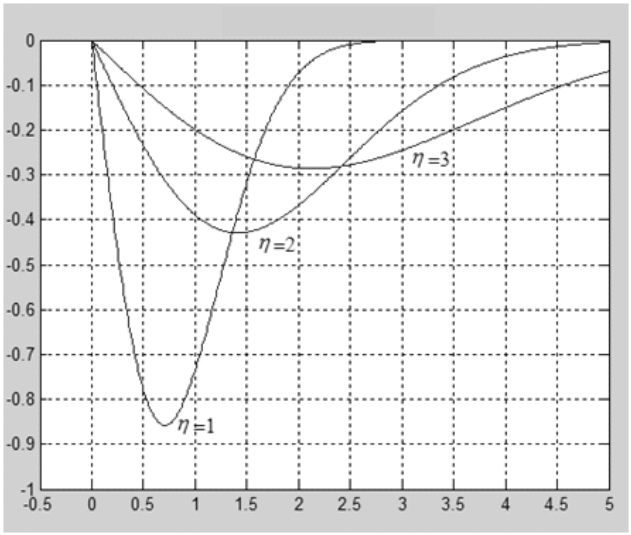

Fig. 6. Influence of shape parameter η on weibull curve under certain parameters β and γ

It can be seen from Fig. 6, when $\eta = 1$, Wilbur curve distribution interval is about 0 ~ 2.5 radian, corresponding to the angle value is about [0°, 143°], in order to adapt [-1.75°, 14°] angle interval, this paper take $\eta = 14°/143° \approx 0.1$, known from the previous discussion, $\beta = 2$， γ=-1.75° = -0.03 radians, the Weibull curve equation to describe the rolling compaction zone the material layer stress distribution is:

$$f(\alpha)=200(\alpha+0.03)\exp(-((\alpha+0.03)/0.1)^2) \tag{8}$$

It can be seen from Fig. 7.

Location parameters

Location parameters γ affect the starting point of the Weibull curve, which is equivalent to move the curve along a coordinates. Fig.8 shows the influence of the location parameters changing to the Weibull curve, when the $\eta = 0.1$, $\beta = 2$.

In fact, after the roller rolling, there is elastic recovery of material layer, that is, passing through the grinding roller lowest point, the materials still has the contact pressure with roller. So the location parameters of the distribution curve, $\gamma \neq 0$. Here for a more accurate representation of the compressive stress, take γ = -0.2, and the preceding discussion shows, $\beta = 2$, and temporarily take $\eta = 1$, according to the actual direction of the compressive stress, add a negative for the curve $f(\alpha)$,get the equation:

$$f(\alpha) = -2(\alpha + 0.2) \cdot \exp(-(\alpha + 0.2)^2) \tag{9}$$

It can be seen from Fig. 9.

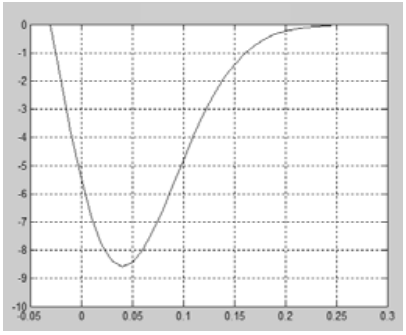

Fig. 7. Weibull curve for describing stress distribution on material layer of roll area

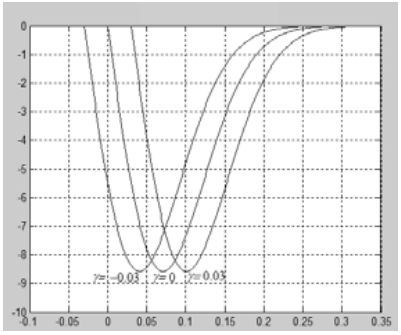

Fig. 8. Influence of shape parameter γ on weibull curve under certain parameters β and η

Fig. 9. Weibull curve, when η=1, β=2, γ=-0.2

Conclusion

1) Theoretically analyzing the force acting on the grinding rollers, and establishing a mechanical model for the grinding roller stress distribution;

2) The form of a three-parameter Weibull distribution curve presented in this paper can better describe the stress distribution in the circle view direction of the roller; the three parameter values of Weibull distribution curve could be got according to the actual mill conditions and operating parameters;

3) Due to the grinding roller having the drum-shaped, so the stress on the rolling compaction zone is more complex, the mathematical equations of the rolling compaction stress and normal pressure are established in this paper, the mathematics equation of the vertical component and horizontal component of the friction acting on the grinding roller surface, as well as the mathematical equation of the vertical force and horizontal force the material role in the grinding roller surface. Making use of MATLAB software, the mathematical model of stress and the force of the roller rolling area of analytical and numerical calculations, and calculate the stress distribution patterns of curve correction coefficient.

This work provides a theoretical basis to study the mill table force and the load conditions.

Keywords: vertical roller mill, grinding roller, load distribution.

Abstract: The width of the grinding rollers are far greater than the arc length of the compaction zone in the circle view direction of the roller, and the actual wear of the mill roll surface also appear in the width direction. Therefore, it is helpful for analyzing the load distribution in the width direction of the grinding rollers, to clarify the state of mill work, and understand the non-steady-state vibration of the mill.

The Material Layer Stress Distribution Curve of the Compaction Zone in the Roller Width Direction

Vertical mill in nonmetallic ultrafine powder preparation has got more and more application. It is discussed in this paper of the vertical mill pressure distribution that relate directly to production efficiency, equipment wear and tear.

The grinding roller of MPS vertical mill is of the drum-shaped. On both sides of the grinding roller width, there will be materials being squeezed out during working, so the stress distribution is uneven on the roller surface. Experiments show that [1,2], the pressure distribution in the compaction zone of the roller width direction is big in the middle, and little on both sides. In the condition of other parameters remain unchanged, the speed - pressure distribution curve near a steep parabola [3].

Mathematical expression that describes the pressure change rate along the width direction of the roller [4, 5] is as follow:

$$p(z) = C_2\left[1-\left(\frac{2z}{l}\right)^m\right] \tag{1}$$

Where C_2 is the constant to be determined, l for the mill roll width, m is the grinding roller axial coefficient.

Eq. 1 describes the pressure distribution between the cylindrical roller and the material layer in the width direction. The grinding roller of MPS vertical mill has a drum-shaped surface, so this paper uses the Eq. 2 to describe the stress distribution in the width direction of the roller. The drum-shaped surface and the angle θ are shown as in Figure 1.

Set mill roll width direction stress distribution function $C_2 f_1$, stress distribution curve f_1 is in the form of:

$$f_1(\theta) = \left[1-\left(\frac{2\theta}{2\theta_0}\right)^2\right] \tag{2}$$

The stress distribution in both directions of the roller circle view and the width view multiplied by undetermined coefficients and integral, the spatial distribution of roll grinding force could be obtained. The calculation of roll grinding force and the actual external load phase equilibrium, in order to determine the undetermined coefficients.

In order to get the undetermined coefficients, the calculation roller force ought to balance with the actual external load.

As the Weibull stress distribution of compaction zone and the parabolic stress distribution of the width direction, the main operating parameters are provided by the factory, therefore the stress distribution can better describe the actual working conditions, and equilibrium with the external load. The research work of this paper have laid the foundation for the further studying the force of roller and mill table as well as the load conditions.

The Normal Pressure on the Grinding Roller Surface

Rolling zone stress *p* and normal pressure *dP*

Compaction zone stress p obtained by multiplying the stress distribution $f(\alpha)$ of the circular view direction and stress distribution $f_1(\theta)$ of width direction:

$$p(\alpha,\theta) = C f(\alpha) f_1(\theta) \tag{3}$$

Where: C is the stress distribution patterns of curve correction factor, $C = C_1 C_2$, the unit Pa.

Roll grinding the surface of the micro-area dA as follows:

$$dA = Rrd\alpha d\theta \tag{4}$$

The micro-pressure micro-area dA dP as follows:

$$dP = p(\alpha,\theta)Rrd\alpha d\theta$$

$$= C\left[1-\left(\frac{2\theta}{2\theta_0}\right)^2\right](20(\alpha-0.03)/0.1)\exp(-\left(\frac{\alpha-0.03}{0.1}\right)^2)Rrd\alpha d\theta \tag{5}$$

The vertical component of the normal pressure $dP(\alpha,\theta)$

The micro-pressure points to the circle center of arc surface in the roller width direction.

$$dP_y = \cos(\alpha)\cos(\theta)dP = \cos(\alpha)\cos(\theta)Cf(\alpha)f_1(\theta)dA \tag{6}$$

Herefore, the vertical component of the surface stress of the roller and of P_y

$$P_y = \int_{-\frac{\theta_0}{2}}^{\frac{\theta_0}{2}} C\left[1-\left(\frac{2\theta}{2\theta_0}\right)^2\right]\cos(\theta)rd\theta)\int_{\alpha_2}^{\alpha_1}(20(\alpha+0.03/0.1)\exp(-\left(\frac{\alpha+0.03}{0.1}\right)^2)\cos(\alpha)Rd\alpha \tag{7}$$

The variable α and variable θ is independent of each other, so you can calculate the integral respectively.

The following integral the stress distribution patterns function $f(\alpha)$ in the roller round view direction. Try to simplify the calculation in the case meet the requirements of engineering precision. Due to the radius of the grinding rollers is large, and the sag depth h is limited, so the integral angle range of the stress $f(\alpha)$ in the circle view direction is not large, according to the previous calculation, the α value range of [-1.75°, 14°]. In order to facilitate integration, trigonometric function in equation (7) near the origin to expand as the Taylor series, the $\sin(\alpha)\approx\alpha$, and $\cos(\alpha)\approx 1-\alpha/2$.

The following calculated the specific values of the vertical component P_y of the roller surface stress. The specific values of P_y can be obtained by integral Eq. 6 or integral Eq. 7, but it is needed to know the specific values of correction factor C of stress distribution shape curve. (The C value is unknown yet); the specific values of P_y can also be obtained through the mechanical analysis of the grinding rollers.

Vertical external force G acting on the roller shown in Fig.2 is equal to the roller weight + 1/3 the gravity of framework + hydraulic loading force. It is known that the hydraulic loading force is 1.4e+6 N, grinding roller weight is 52000kg, 1/3pressure framework weight = 37000/3 = 12333 kg. So G should be equal to 2.03e+6 N. Because of the vertically downwards external force G acting on the grinding roller should be equal to the vertical component P_y of the grinding roller surface compressive stress, and P_y should be equal to 2.03e+6 N. shown in Figure 2.

The specific value of the stress distribution curve factor C is calculated as -21.126MPa.

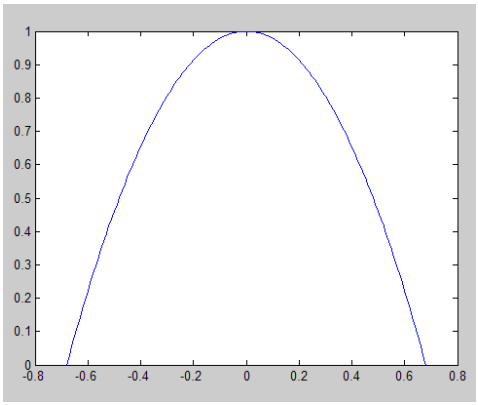

Fig. 1. Stress simulation curve in roll width direction

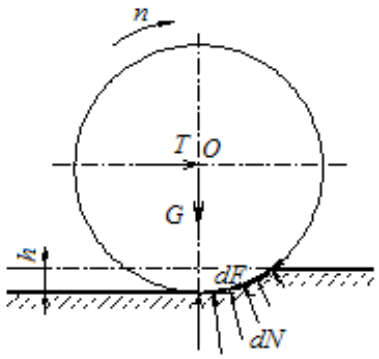

Fig. 2. The residual deformation of the materials layer

D stress distribution

The stress distribution between the roller and the material in the top view direction is shown in Figure 3.

Using MATLAB software to draw the area of the roller rolling three-dimensional stress distribution shown in Figure 4.

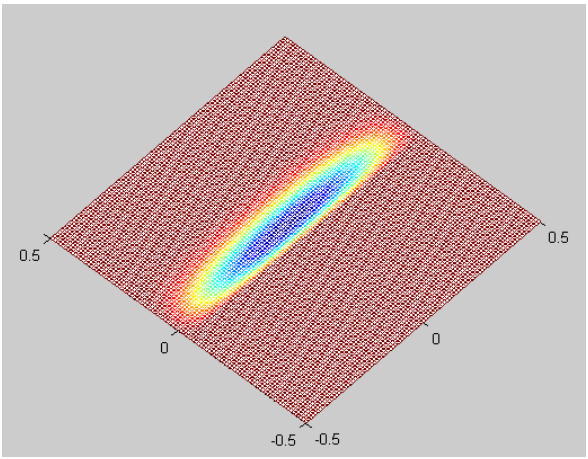

Fig. 3. Stress distribution of rolling area in top view direction

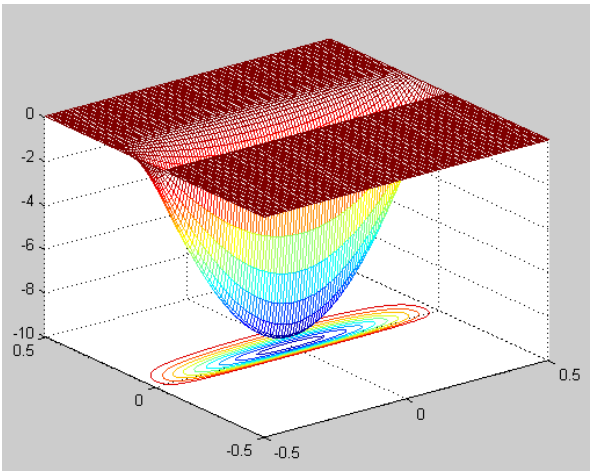

Fig. 4. 3D graph of stress distribution in rolling area

The three-dimensional graphics of the compaction zone stress distribution is shown in Figure 4. Intercepted part of the Weibull curve below the horizontal axis, said that the compressive stress.

It can visually be seen from Figure 4: The stress distribution in the central region is much larger than the stress on the edge region; the distribution range of stress in roller round view direction is much smaller than the distribution range of roller width direction stress, the crushing of the material is mainly due to the compaction of mill roll width direction.

2.4 The horizontal component $dP(\alpha,\theta)$ of the pressure

The horizontal force components of material layer acting on the grinding roller constitute of the normal pressure horizontal component and the friction horizontal component. Among them, the horizontal component dP_x of the normal pressure on the micro-area dA as follows:

$$dP_x=\cos(\theta)\sin(\alpha)dP=\cos(\theta)\sin(\alpha)f(\alpha)f_1(\theta)dA \tag{8}$$

In order to carry out the numerical integration, it is needed to determine the integration upper and lower limits of θ angular.

Known width b = 1002mm grinding roller mill roll width direction of circular surface of radius r = 800mm. Set mill roll circular surface corresponding central angle $2\theta_0$, and from down the y axis to any position of the central angle is set to θ, the range of variation of the angle θ: [- θ_0, θ_0]. Calculated:

$$\theta_0=\arcsin(b/2r_1)=\arcsin(501/800)=0.6767(\text{rad}) \tag{9}$$

It is worth noting that $f_1(\theta)$ in the z-axis projection, symmetry, and therefore cancel each other out.

The Vertical and Horizontal Component of the Friction of Material Role on the Roller Surface

The $dP(\alpha, \theta)$ multiplied by the friction coefficient μ to get the friction of the dF:

$$dF=\mu\, dP(\alpha,\theta) \tag{10}$$

The vertical component dF_y of the friction：

$$dF_y=\mu\sin(\alpha)dP(\alpha,\theta) \tag{11}$$

The horizontal component dF_x of the friction：

$$dF_x=\mu\cos(\alpha)dP(\alpha,\theta) \tag{12}$$

$\mu\sin(\alpha)$ is a higher order, the calculation of the vertical load can ignore the influence of the friction force F_y. Friction force horizontal component F_x in the calculation of pressure framework torsion could not be ignored.

Vertical Force and Horizontal Force of the Material Role in the Surface of the Roller

In order to calculate the pressure on the framework of the role of the grinding rollers horizontal force, the horizontal component of the normal pressure in the dP_x and friction horizontal component dF_x summation:

$$\begin{aligned} dP_x+dF_x &= \cos(\theta)\sin(\alpha)dP(\alpha,\theta)+\mu\cos(\alpha)dP(\alpha,\theta) \\ &= (\cos(\theta)\sin(\alpha)+\mu\cos(\alpha))dP(\alpha,\theta) \\ &= (\cos(\theta)\sin(\alpha)+\mu\cos(\alpha))p(\alpha,\theta)dA \end{aligned} \tag{13}$$

Take $p(\alpha,\theta)=f(\alpha)f_1(\theta)$，$dA=Rrd\alpha d\theta$ into Eq. 12，And integral equation on both sides:

$$\begin{aligned} &P_x+F_x \\ &=\int_{-\frac{\theta_0}{2}}^{\frac{\theta_0}{2}}\int_{\alpha_2}^{\alpha_1}C_1\left[1-\left(\frac{2\theta}{2\theta_0}\right)^2\right][\cos(\theta)\sin(\alpha)+\mu\cos(\alpha)])(20(\alpha+0.03)/0.1)\exp(-\left(\frac{\alpha+0.03}{0.1}\right)^2)Rrd\alpha d\theta \end{aligned} \tag{14}$$

In order to calculate the integral of the right hand side, appropriate to simplify the integrand. Round view of the direction of the angle α in smaller intervals, so the origin near the Taylor series expansion: $\sin(\alpha)\approx\alpha$; $\cos(\alpha)\approx1-\alpha^2/2$; into Eq. 3-23, are:

$$P_x+F_x=200C_1Rr\int_{-\frac{\theta_0}{2}}^{\frac{\theta_0}{2}}\int_{\alpha_2}^{\alpha_1}\left[1-\left(\frac{2\theta}{2\theta_0}\right)^2\right][\cos(\theta)\cdot\alpha+\mu(1-\alpha^2/2)])((\alpha+0.03))\exp(-\left(\frac{\alpha+0.03}{0.1}\right)^2)d\alpha d\theta \tag{15}$$

here

$$P_x = \int_{\alpha_1}^{\alpha_2} \int_{-0.68}^{0.68} (1-(2z/(2\times 1.36)^2)\cos(z)kf(\alpha)(\sin\alpha+\mu\cos\alpha)dzd\alpha \tag{16}$$

The vertical and the horizontal force acting on the roller surface from materials are offset by the force T of the pressure framework.

X-axis components of the normal pressure and the friction acting on the roller are shown in Figure 5.

The vertical force acting on the grinding roller surface by the materials should be equal to $P_y + F_y$, because of the $\mu\sin(\alpha)$ is a higher order, so the influence of friction F_y could ignored, that is, the vertical force of materials acting on the surface of roller approximately equal to P_y.

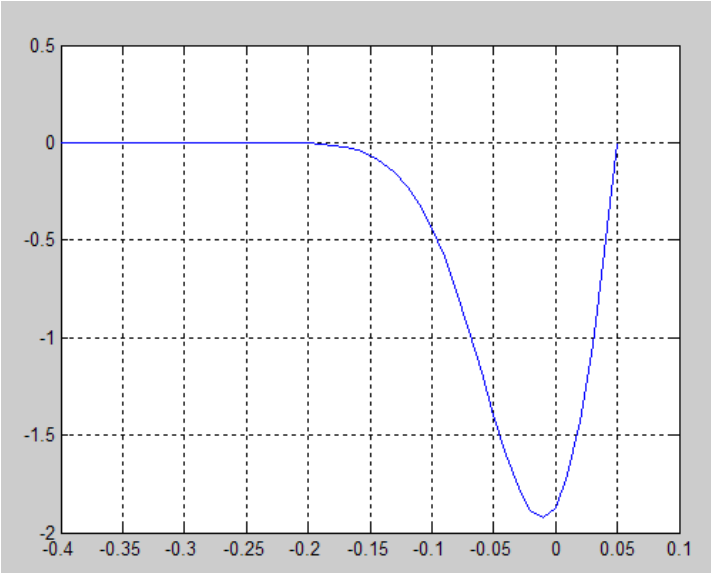

Fig. 5. *X*-axis component of normal pressure and friction force on roller suffered

Conclusion

1) The three-dimensional stress distribution graph in the rolling compaction is obtained. Be intuitively seen from the stress distribution graphic: the stress in central area is much larger than the stress of the edge region; the stress distribution in the circle view direction of the grinding roller is far less than the range of width direction of the mill roll, that means the crushing of the material comes mainly from the rolling of grinding roller in width direction.

2) The horizontal force between the roller and the material layer comes from the horizontal component of the normal pressure *P* and the friction force *F*, ie, P_x+F_x; the vertical force comes from the vertical component of the normal pressure *P* and the friction force *F*, namely $P_y + F_y$.

This work provides a theoretical basis to study the mill table force and the load conditions.

Keywords: Gas Metal Arc (GMA) Welding, Mahalanobis Distance, Root Mean Square (RMS), Levenberg–Marquardt algorithm, On-line Control

Abstract: With the development of computational technology, neural network has attracted the more and more attentions to reveal the relationships between the process parameters and welding geometry. However, the Gas Metal Arc (GMA) welding is complex and of multiple interactions so that mathematical model for welding parameters has not been achieved. Neural networks have been noted as being particularly advantageous for modeling systems which contain noisy, fuzzy and uncertain elements, while a sufficient algorithm is employed. In this study, Levenberg-Marquardt algorithm was employed into GMA welding process. Mahalanobis Distance (MD) was measured to determine the on-line welding quality to avoid joint failure as welding quality. To get an optimal neural network, cases with different configurations were carried out. The Root of the Mean sum of Squared (RMS) error was adopted to evaluate the accuracy of the prediction by neural networks with LM algorithm. The results presented that the proposed algorithm had the superiority of high accuracy that can be used in the on-line welding process.

Introduction

GMA welding process is a very complex process due to the fact that it involves multiple interaction of solid, liquid, gaseous and plasma-state. This complexity makes the sensing and controlling of the welding parameters in the welding process very difficult to perform real-time. Since measuring, sensing, or monitoring, the welding parameters of a physical system were of primary importance in the application of any automatic control technique. Therefore it is necessary to develop an intelligent neural network to obtain suitable welding parameters in the automatic GMA welding process to achieve the desired MD and weldability.

In recent years, neural network has becomes a very useful tool in the modeling of inter-relationships between input and output variables of many complicated systems. The most being well known of supervised technique is backpropagation neural network, which adjusts initial randomized weights during training according to the steepest gradient along the error surface [1]. However, it was also pointed out that the backpropagation method encountered slow learning progress and convergence to a false local minimum according to works done by JiříŠíma [2], Kim [3], Fukuoka [4], etc. Thus, for a real-time GMA welding process, a better algorithm is required.

Meanwhile, it is hard to identify the quality of input parameters since the waveform of welding current and arc voltage obtained from the on-line monitoring system differ slightly. Thus, a descriptive statistic of MD, which is a unitless measure introduced by Mahalanobis in 1936 [5], is applied to character the quality of the welding parameters. According to the description, a point that has a greater MD from the rest of the sample population of points is said to have bigger difference. In other words, in a group of experimental data which most of them are good, the one with a greater MD can be considered as false one.

This study attempts to use an optimal neural network to establish a prediction system of MD for GMA welding process. And the feed-forward backpropagation neural network with Levenberg-

Marquardt algorithm is firstly established. Secondly, the averaged RMS error is calculated to evaluate the accuracy of the optimal neural network. Finally, comparison of the qualitative and quantitative analysis of GMA welding fault based on MD by Levenberg-Marquardt algorithm with different numbers of neurons is presented. In order to analyze the influences of the input parameters (welding current and arc voltage) on the resulting output parameter (MD). The result shows that the Levenberg-Marquardt algorithm is the preferred algorithm to construct neural network in the prediction of MD for automated GMA welding process.

Experimental procedures

The GMA welding process, sometimes called Metal Inert Gas (MIG) welding, is a welding process that yields coalescence of metals by heating with a welding arc between a continuous filler metal (consumable) electrode and the workpiece. Fig. 1 presents the experimental setup of GMA welding process. In the GMA welding process, the bead geometry is determined by wire feed rate, welding current and welding voltage, which is controlled by the computer controller. Not only, welding current and wire feed rate dominate the penetration for single pass welds, but also arc voltage dominates the bead width and has an influence on the penetration since it controls the arc shape [6].

A steel plate is conducted as a multi-parameters process. The dimensions of welding plate and the direction for butt GMA welding process on a test specimen is shown in Fig. 2.

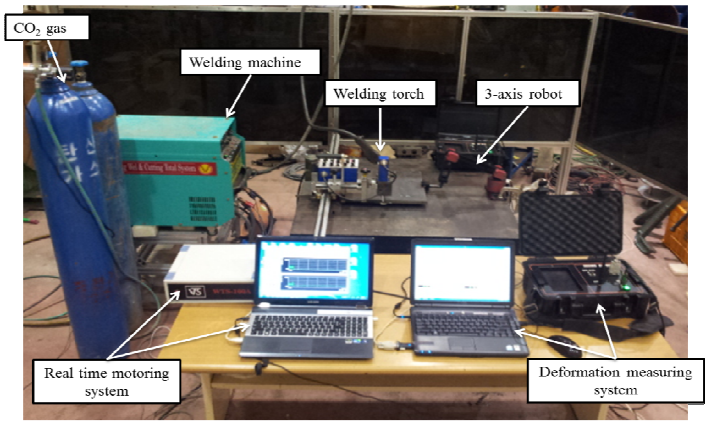

Fig. 1 Experimental setup of GMA welding

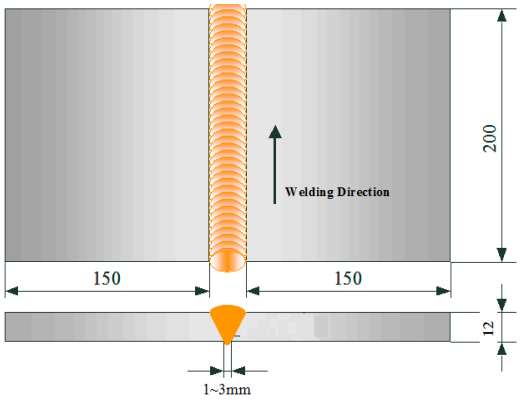

Fig. 2 Overview of GMA butt weld specimen process

Description of Mahalanobis Distance

MD has successfully been applied to a broad range of cases mainly because it is very sensitive to inter-variable changes in data. It is measured in terms of standard deviations from the mean of the samples. It takes into account the correlations of the data set and is scale-invariant to provide a statistical measure of how well an unknown sample matches a known sample set. In other words, if the magnitude of MD derived from a welding current C_i and arc voltage V_i is smaller than a certain value, the parameter of (C_i, V_i) can be considered as a suitable value and good weld will be produced. The smaller the MD is, the better the weld quality will be [7].

The MD takes advantages over classical statistical approaches in several aspects. First, MD considers the variance and covariance of the measured variables rather than just the average value. It weights the differences by the variability range in the sample point direction. Second, it also accounts for the ranges of acceptability between the variables which is useful since most systems are not just comprised of independent variables rather dependent variables are also impacting the system's performance. Besides, it calculates distances in units of standard deviation from the group mean. By using standard deviation, the attribute under consideration is given in the original units, which relates the results to the original data. Using Levenberg-Marquardt algorithm to establish a

neural network for GMA welding process is composed of two phases: training and testing of the neural networks with experimental welding data.

To provide the reliable measures for recognition of welding current and arc voltage on bead geometry as welding quality, the transformed equation is defined below:

$$M_d = \frac{V_i'^2 - 2rV_i' + C_i'^2}{1 - r^2} \tag{1}$$

Where V' and C' indicate the normalized value of arc voltage and welding current, and r is the correlation coefficient after normalization.

Modeling of GMA welding process

In this work, the welding parameters are mapped to the MD through the internal representation of neural network with Levenberg-Marguardt algorithm. Data obtained from the experiments and regression models are provided to a network at the learning stage. During network learning, the network output is compared with the desired output and the connector weights inside the network adjust to minimize the difference. The error is then propagated backwards through the network and weights are changes based on the Levenberg-Marguardt algorithm. This learning process is an iterative process and learning will stop once an acceptable error is achieved. When the trained network is presented with new input (beyond training), the network responds according to the knowledge it has acquired. Fig. 3 shows the major input and output parameters associated with the quality characteristics in robotic GMA welding process.

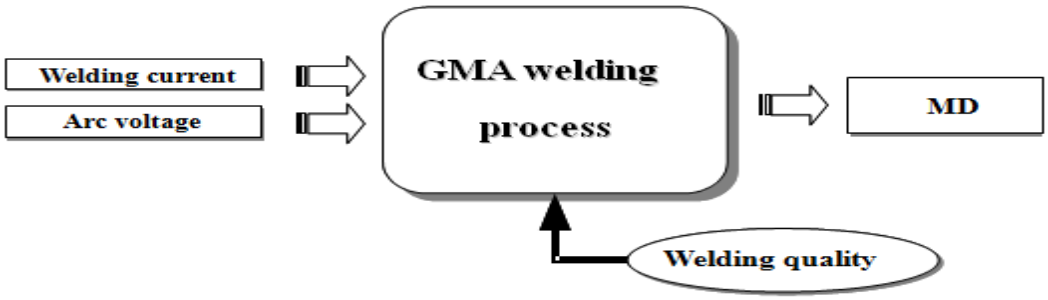

Fig. 3 Input and output parameters of the gma welding process

In this study, a one-layer feed-forward backpropagation neural network is employed as a tool for mapping the complex and highly interactive process parameters such as welding current and arc voltage into the MD to predict the optimal MD in robotic GMA welding process.

The convergence criterion for the developed networks is determined by the average RMS error between the desired output value y_i and predicted output value y'_i for the *ith* prediction, i.e.:

$$RMS_{error} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - y_i')^2} \tag{2}$$

Where i is the number of training data or testing data.

In this paper, the Levenberg-Marguardt algorithm is employed because generally this algorithm could provide a faster convergence than the gradient descent algorithm used in the error backpropagation algorithm. Also, the development and the training of the neural network are carried out on a Pentium PC using MATLAB. The training process continues until either the error goal is met or the maximum number of epochs is completed. The neural network configuration setup for the training is shown in Table 1. The neurons of the input and the interpolation layers are employed to accept the welding parameters and then generate the estimated MD.

TABLE 1 NEURAL NETWORK CONFIGURATIONS FOR THE TRAINING WITH THE LEVENBERG-MARQUARTDT ALGORITHM

Four layer network	Four neurons in input layer, one hidden layer, one neuron in output layer
Max._epoch	500
Error goal	1e-6
Learning rate	0.01
Multiplier for increasing MU	10
Multiplier for decreasing MU	0.1
Maximum value for MU	1e+10
No. of neurons in hidden layer	2-16 (in steps of 2)
Number of training sets used	one

Results and Discussion

A series of input variables (12400 examples) are used for training the neural network. Then the trained neutral network is tested by 100 new data. Network configurations with different numbers of neurons in the hidden layer are studied. Many attempts are made to find a result showing the minimum error or the maximum prediction accuracy. The discussion presented here is based only for the case of the optimal results obtained with different configurations. In order to understand the effect of the network parameters on the MD, the number of neurons is intentionally chosen from two to sixteen neurons in a hidden layer. The accuracy of the developed neural network was evaluated by the RMS error between the measured and the predicted values for the training and the testing process (Fig. 4). The histograms indicate the RMS error in the training process is not directly related to the increase of the number of neurons in the competition layer. To the testing phase, the average RMS error of the testing set is almost the same as that of the training set, which means that the network has good generalization ability for the modeling of the GMA welding process. Furthermore, the lowest RMS error obtained by using this algorithm is as low as 0.0014 with 14 neurons in hidden layers in 284 training cycles. It is clear that the 2-14-1 network configuration seems to be best fit for the prediction of the MD with the lowest RMS error. Therefore, the network with this configuration was selected for the good learning ability.

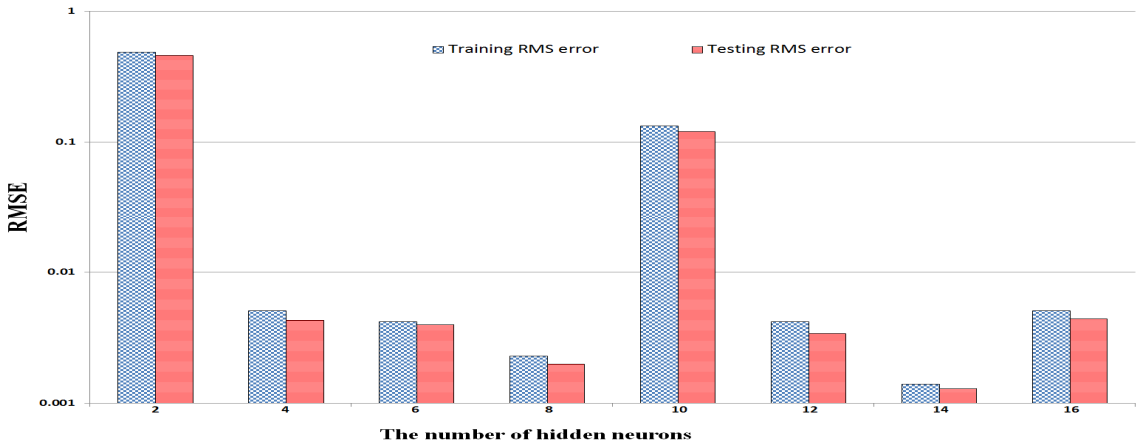

Fig. 4 The value of training and testing RMS error for the developed neural network with a number of neurons between 2 and 16 in the hidden layer

The results of the measured MD and predicted MD using the developed neural network model by the Levenberg-Marquardt algorithm method with the 2-14-1 network configuration are compared and shown in Fig. 5. Where the horizontal ordinate represents the predicted MD, the vertical

ordinate presents the measured MD. The dash line of best fit is drawn using regression computation to get a direct view. It is evident that the predicted MD completely coincides with the measured one

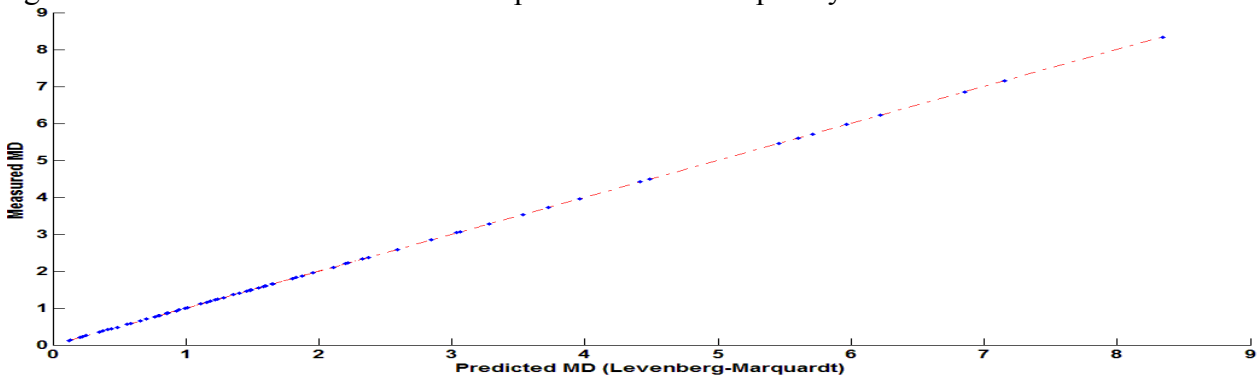

Fig. 5 Comparison between the measured and predicted MD with the developed algorithm

Summary

In this study, we have developed a new approach to predict MD in automatic GMA welding process using the neural network. The Levenberg-Marquardt algorithm neural network with one-hidden-layer in configuration of 2-14-1 is found to be more effective and greater precision than any other structures, as it can provide accurate prediction and reduce the RMS error to a significantly small value. Also the developed algorithm is able to predict that the MD completely coincides with the measured MD and increases reliability of welding quality in GMA welding, which can be proposed for real-time welding quality predetermination on automatic control system of on-line GMA welding process.

Keywords: High frequency cladding Hydraulic prop Component analysis

Abstract. Ni-based cladding coatings are prepared on the surface of hydraulic prop mobile column by high-frequency induction cladding with different current. Microstructures of coatings are analyzed by metallographic microscope as well as SEM, while coatings and matrix elements are analyzed by EDS. The results show that metallurgical bonding is formed among transition regions of matrix and coatings with obvious white band, when cladding frequency is 250KHz and current is 1160A. The microstructures of coatings are eutectics of "austenite + carbide", relatively uniform. During the process of cladding, Fe as well as Mn in matrix permeats to coatings; while Si element in coatings permeats to matrix. As a result, the Fe content of trasition regions is raised, and the contents of Ni and Cr is comparatively reduced.

Introduction

Equipments are chronically exposed to damp and corrosion circumstance with high air moisture under coal mine. A part of mobile column of single hydraulic prop out of cylinder is easily corroded under harsh environment with parts breaking. Chromium plating on the surface of column [1-4] is a traditional way, but electroplating production, with complicated technology and high cost will pollute the environment seriously, which is not accord with sustainable development policy in our country.

High frequency cladding, with coatings uniform thickness, high strength and wear resistance as well as low production cost, is gradually becoming research focus home and abroad. At present, research on this region is basically aiming at such solid specimens as axis, plate and tooth; as thin-walled specimen, mobile column with low heat capacity, has strict demands on parameters, which directly determine the depth of heat-affected zone and performance of cladding coatings. In this paper, high frequency cladding technology on the surface of mobile column, as well as microstructure of specimens, is the research emphasis.

Experimental Materials

The experiment adopts 27SiMn as mobile column material with length 400mm, a diameter of 76mm, pipe wall thickness 5mm; self-fluxing alloy powder N45 is adopted as cladding material.

TABLE1 CHEMICAL COMPOSITION OF ALLOY POWDER AND MOBILE COLUMN[11] (MASS FRACTION,%)

	Ni	Cr	B	Si	Fe	C	Mn	S	P
Ni45 alloy layer	Bal.	12.5	1.9	4.1	6.6	0.34	—	—	—
27SiMn	≤0.03	≤0.03	—	1.1~1.4	Bal.	0.2~0.3	1.1~1.4	≤0.04	≤0.04

Experimental Results and Analysis

Macroscopic Morphology of Metallographic Specimen

Fig. 1 is macrophotograph of the metallographic specimen after cladding, when cladding frequency is 250KHz and current is 1160A. From it, it can be seen that, vaulted silver white part is structure of specimen, in the middle of test block; while upper part of the structure is alloy coating and the black is mosaic powder. Besides, it also can be seen that the coating is uniform. Meanwhile, coating and matrix combine closely.

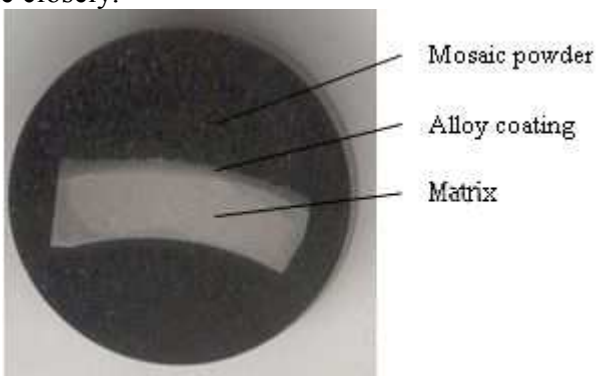

Fig.1 Macrophotograph of the Metallographic Specimen

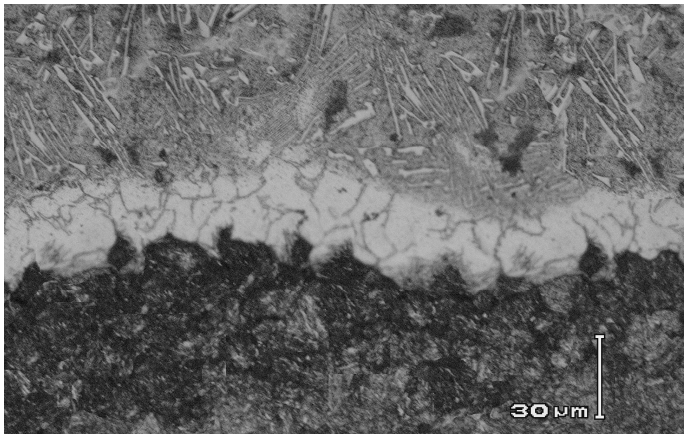
Microstructure of Cladding Coating

Fig. 2 is the microstructure of claddding coating. From it, it can be seen that, upper side is alloy coating and the lower is matrix. Besides, a white zigzag band can be seen obviously in the juncture of coating and the matrix. Structure of the band is eutectics of "austenite + carbide", coarse and uniform compared with the coating. Dendritic austenite structures increase obviously, near to the transition and the components of the coating and the matrix are completely permeated and diffused. After induction heating, the structure of coating is cooled rapidly, and the alloy elements are left in the obvious white band composed in the matrix. What's more, the zigzag shape of white band has the function of mosaic, which is beneficial to increase the bonding strenth of coating and matrix at the interface.



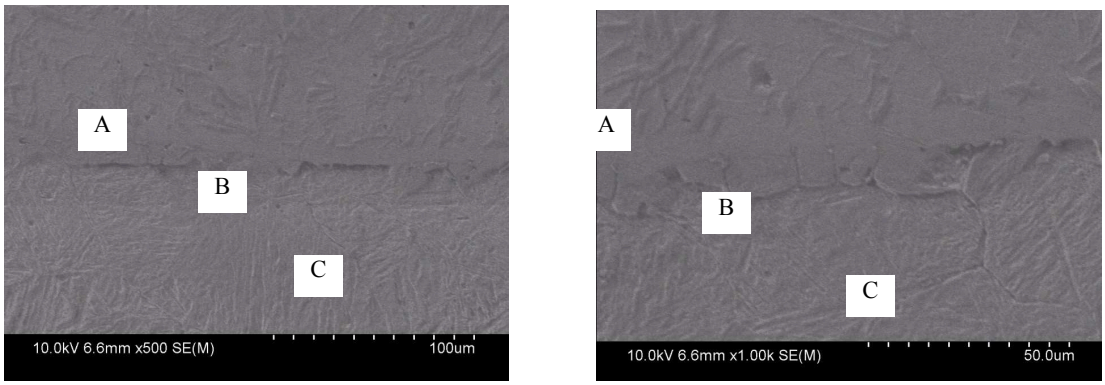


Fig.2 The Microstructure of Cladding Coating

Component Analysis of Cladding Coating and Matrix

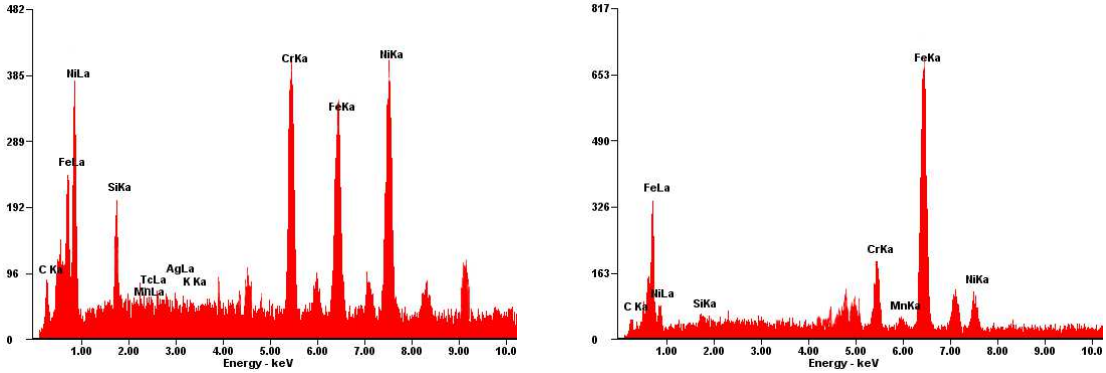

Fig. 3 are SEM micrographs of the cross section for cladding coating. And from Fig. 3(a), it can be seen that coating is composed of compact structures and dendritic one, and the juncture of coating and matrix is basicly combined. From Fig. 3(b) is SEM photo amplified 1000 times, from which, it can be seen that, a small amount of pores apear in the coating and it is because that some air in the alloy can't be eliminated during the process of high frequency cladding.

(a)×500 (b)×1000

Fig.3 SEM Micrograph of the Cross Section for Cladding Coating (A—Cladding Coating；B—Transition Region；C—Matrix)

Fig. 4 are energy spectrum distribution of cladding coating and matrix. And Fig. 4(a) is the spectrum analysis of cladding coating, from which, it can be seen that the coating mainly contains Fe, Cr, Ni, Si, C as well as small amount of Mn. From Tab.1 above, it can be seen that Mn is basicly not existed in the alloy layer but in the matrix material, and obviously, Mn, which belongs to the matrix material, permeats to the cladding layer during the process of high frequency cladding. Fig. 4(b) is the spectrum analysis of transition material, from which it can be seen that transition religion mainly contains Fe, Cr, Ni, Si as well as a small amount of Mn permeating from the matrix. The content of Fe has greatly increased relative to the coating, while the content of Ni, Cr has obviously reduced. And the reason is that the Fe contained in the matrix permeates to the transition religion during the high frequency cladding, with the content of Fe in transition increasing and the Ni, Cr of coating relatively reducing.

(a)—Energy spectrum distribution of cladding coating；(b)—Energy spectrum distribution of Transition region；

Fig.4 Energy Spectrum Distribution of Cladding Coating and Matrix

Conclusion

Metallurgical bonding is formed among transition regions of matrix and coatings with obvious white band, when cladding frequency is 250KHz and current is 1160A.

The microstructures of coatings are eutectics of “austenite + carbide”, relatively uniform. SEM micrographs of the cross section show that the coating, with a small amount of pores is composed of compact structures and dendritic ones.

Keywords: Humidifier, Material structure, Appearance design, Color design, Student consumer group

Abstract: The winter in northern China is cold and dry. With the centralization and generalization of heating devices, people have become more and more aware that dry environment does not only cause loss of water in the body, but also breeds numerous germs threatening health. In response, humidifiers are created. The widespread use of air-conditioners because of climate has accelerated the development of humidifiers. Although it is expanding, the potential consumer market of humidifiers has not been fully developed as the designers ignore students who are believed to be a big consumption group. This paper touches three aspects of humidifier design: material, appearance and color. According to the research, the humidifier market is believed to be better developed if humidifiers are designed to meet students' consumption concept by taking care of the three aspects.

Introduction

As people nowadays are pursuing life of better qualities, they have higher requirement for living environment. However, heating applied in cold dry winter makes people feel dizzy, thirsty and uncomfortable if they stay indoors for long. A large number of researches have shown that only moderate air humidity can make things full of life. Only when the indoor humidity stays between 45% and 55% RH can furniture be prevented from being deformed or damaged due to excessive dryness or humidity. However, the indoor humidity of the households in northern China in winter is merely 10% to 15% RH. Such a dry environment can generate high-level static electricity. A humidifier can produce humid air to fill a room with negative oxygen ions that can eliminate static electricity. Therefore, controlling air humidity is of great significance to health and life. When preparing for exams, many in-school students are vulnerable to diseases because of the change of humidity as germs are generated and infection sources are spread rapidly. As a result, students often fail to perform well in exams.

With student consumers as its research objects, this paper talks about appearance, material and color designs of humidifiers. In addition, it's suggested in this paper that the circuit design of humidifiers should be improved so as to create lower-powered humidifiers which can work in case of power failure.

Birth and Concept of Humidifiers

Birth of Humidifiers

Because of the dry climate in northern China, people often feel skins dry and throats sour after getting up in the morning. Such discomforts are worsened especially after November 15th when the supply of central heating starts. The discomforts mentioned above are caused by low air humidity. According to medical research, dry air accelerates the loss of water in the body, which can cause wrinkles beyond repair and thus speed up the aging of the body. What's worse, dry air can cause diseases of the respiratory system especially among vulnerable groups such as old people and young children. The first humidifier in China hence came into being in Beijing Yadu Indoor Environment Protection Technology Co., Ltd. in 1987.

Concept of Humidifiers

As a kind of indoor air moistener, a humidifier consists of a water tank, moisture spreading elements, and a moisture outlet valve. The water tank matches the heating bag. Positioned in the water tank, the moisture spreading elements are partially submerged. Water is heated by the heating bag, and evaporates to humidify the in-door air. Changing the number of moisture elements can adjust humidity. It can not only make in-door relative humidity reach the required level, but also provide certain amount of hot non-potable water.

Development State of Humidifiers

In the current market, humidifiers can be classified into two types in terms of service environment: the industrial type and the household type. In terms of technological principles, there are four types: ultrasonic humidifiers, purity degree humidifiers, spray mist humidifiers, and electric heating humidifiers. According to the ways of placement, there are cabinet-type and floor-type. The majority of humidifier consumers are office workers; the number of student consumers is not large. The main reasons for such a phenomenon are as follows. 1. The prices of humidifiers are beyond the students' purchasing power. 2. Electricity supply in school dormitories is restricted and power failure is set to a certain limitation. 3. Humidifiers are oversized, taking up the limited storage space in dormitories. 4. Humidifiers make sounds, disturbing school fellows.

Research on Humidifier Material and Structure Design

Research on External Structural Material of Humidifiers

Most humidifiers in the current market are made of plastics. Some are made of other materials such as ceramic and synthetic wood, and they are of higher prices, which is not easy to be accepted by the potential student consumption group. Therefore, the materials to be studied in this paper are plastics.

The American Society of Testing Materials (ASTM) defines plastics as typically organic polymers of high molecular mass. They are of solid shape when processed. During manufacturing and processing, they are moldable as it flows. Because of its universal use, plastics have produced heavy white pollution, causing great damage to the ecological environment. Now the environmentally-friendly plastics have come into being in response to the wave of green designs around the world. An excellent designer can design humidifiers meeting students' consumption concept only when he or she fully understands material properties and strives to obtain win-win interests for economy and environment. Plastic materials used to make humidifiers can be classified into following types:

(1) Acrylonitrile-Butadiene-Styrene (ABS): As one of the five major synthetic resins, ABS resin has good heat resistance, low-temperature resistance, chemical resistance, easy workability and dimensional stability. Besides, it is not only easy to color, but also useful in secondary processing such as hot-pressing and splicing. With prominent mechanical and thermal properties, ABS resin is widely used in household appliances such as air-conditioners, humidifiers, and so on.

(2) Polypropylene (PP): PP is a thermoplastic resin made from propylene. According to the methyl position arrangement, it can be classified into three types: isotactic polypropylene, atactic polypropylene, and syndiotatic polypropylene. The polypropylene is milk white high-crystallized polymer that is non-toxic, odorless, and flavorless. It has good properties of heat-resistance, flexural fatigue resistance, erosion resistance and electrical insulating. Because of its bad impact resistance and easy-aging, some additives, such as zinc oxide, can be added to remedy its weaknesses.

(3) Polystyrene (PS): PS is of linear structure made from monomer styrene. It is made in the ways of massive polymerization and emulsion polymerization. As a transparent raw material, polystyrene can be widely used when transparency is required in vehicle lampshades, clear parts of daily use, transparent glasses and jars, etc. It has good heat-resistance, low water-absorbing quality and strong radioactivity-resistance.

The three plastics mentioned above are non-toxic by themselves, and have their own advantages and disadvantages. Designers can take advantages of their properties to the fullest by appropriately adding some environmentally-friendly additives to them.

Research on Internal Structural Material of Humidifiers

Considering the facts that electricity supply is restricted and power failure is set in student dormitories, and that all humidifiers available in the current market must be powered on, it is necessary to design a kind of humidifiers that can work with a battery.

An important material named wet film is applied inside humidifiers. Generally, it can be classified into four types: compound type, which is corrosion-resistant, bacterium-proof, repeatedly cleanable, and durable for eight to ten years; fire-proof white compound type, which is fire-proof, water-absorbing, and easy-for-cleaning, and durable for eight to ten years; glass fiber type, whose properties are similar to the former two, but is used less and less because it is fragile and the glass fiber dust is harmful to health; metal hole type, which is greatly fire-proof, but is not recommended because of its bad performance of humidifying.

Through studying and improving the interior material of circuit design and structure, humidifiers can still be used in case of power failure in school dormitories. Currently most humidifiers are powered on by an external power source. If designers want to design humidifiers that can be powered on both internally and externally, they should adopt ultrasonic humidifier theory. By adopting the theory of ultrasonic high frequency oscillation, water can be atomized into ultramicrons of 1 to 5mm, spraying into the air and humidifying it. The ultrasonic humidifiers consist of a power circuit, a control circuit, an oscillating circuit, a draught fan, and a transducer (piezoelectric ceramic piece). It is feasible to use batteries to supply power for the internal circuit as the device is powered with direct current. There are two ways of power-supply if external power source is adopted. One is to use the transformer, which is applied to different types of humidifiers because of its powerful overload capacity, to power the oscillating circuit after it lowers down the rectifier filter. The other is to use a switching power source to supply power, whose features are the evident reduction of weight and high power-supply efficiency. If adopting internal power-supply, designers can use layer-built battery to power the device. Its maximum voltage can generally satisfy it. Therefore, based on the current technology, humidifiers using a direct power source and a built-in battery can be designed. Given this, humidifiers can work normally with an external power supply when power is on, or with a built-in battery when power is off. This design is very practical for students.

Research on Appearance and Color Design of Humidifiers

Research on Humidifier Appearance Design

The appearances of the humidifiers available in the market can be classified into following types: cartoon images, simple geometries, and artworks. To win student consumers, designers should consider saving materials, lowering the cost, and raising water volume. Besides, they should design humidifiers meeting to students' aesthetic standards by creating formal beauty. To school students at different ages, appearance designs can vary accordingly. To junior middle students, for example, designers can make use of popular cartoon images by appropriately making some changes. To senior high school students, however, designers should focus on special styles based on guaranteeing the basic functions of humidifiers as they are more mature than junior middle school students and more rebellious than university ones. While to university students, appearances should merely be simple and fashionable, for example, geometry-shaped ones. Owing to limited space available in school dormitories, designers should design humidifier packing of hang-up type and stickup type according to different appearance designs. Humidifiers can be hung up at bed side or tied to one of the supporting bars on the bed. The external packing of those designs, of course, should be made of environmentally friendly materials with good air permeability and insulating property.

Research on Color Application in Humidifier Design

For its quick acceptance by students, humidifiers should be designed in appearance to satisfy students' beauty-appreciation. In addition, colorific collocation is especially important. When it comes to colors, designers should consider which materials can be colored easily, which pigments are environment-friendly and harmless, and the color and lustre of which materials can last for a long time. Colors have three properties: hue, lightness, and purity. Hues are categorized into 24

types, including red, orange, yellow, blue, green, purple, and intermediate colors. Different hues have different color temperatures. Lightness of colors actually refers to light and shade of colors. Light colors make people feel relaxed and light-hearted; dark colors make people feel pressured and heavy-hearted. With gray is added to a color, its purity changes. For example, when gray is gradually added to yellow in a certain degree, yellow turns to grayish yellow which may provoke nostalgia.

Different colors bring people different feelings, such as coldness and warmness, heaviness and lightness, softness and hardness, strongness and weakness, heavy-heartedness, excitement, quietness, gorgeousness, simplicity and so on. Colors are not emotional. However, influenced by conventional concepts, various colorific collocations, and different textures of differently colored materials, consumers unconsciously associate different colors with different emotions. For example, if a humidifier is designed yellow and table lamp-like, it may make people feel cozy when placed in a bedroom. It can be ornamental, as well as functional, which makes it a perfect combination of appearance and function. Black makes people feel serious, greeny yellow relaxed and light-hearted, and blue calm and gloomy. Different collocations of colors create different visual effects. For example, pink glass material and Sailor Moon images may make a humidifier appear lovely, sweet and dreamlike, and accepted more easily by girl students in junior middle schools. Geometric shapes made of purple-and-white compound type plastic strips may make a humidifier look elegant, simple, but not plain, and accepted more easily by university student consumers. People in different age grades and of different genders may have different preference for colors. Only based on full understanding the colorific preferences of people in different age grades and of different genders, qualitative and quantitative analysis and assessment, can we design humidifiers accordingly to satisfy the needs of student consumers.

Conclusion

As the living standard of Chinese people has been increasingly improving, the market of humidifiers is enlarged gradually with the popularization of electric equipment. However, humidifiers have been accepted only in big cities. The importance of humidifiers is still overlooked in towns and villages in Chinese countryside. Students as a large consumption group have been neglected by businessmen. Humidifiers should be properly designed with various factors taken into consideration such as material, appearance, colors, and the living condition of students. Cheap and high-quality humidifiers that can work in case of power failure are bound to enjoy a better market. Renovated humidifiers will not only be accepted by students, but also become a favorite of people fond of beauty.

Keywords: iron ladle; finite element method; stress; deformation

Abstract: In this paper, iron ladle stress and deformation has been accurately calculated using finite element analysis software ANSYS based on 260t iron ladle in standing, lifting, tipping working conditions. Distribution of stress field was obtained. The stiffness and strength of the iron ladle has been evaluated. The results show that the iron ladle in the standing, lifting and tipping working conditions, structural deformation is small, the strength and stiffness meet the requirements. This research extends the working life of 260t iron ladle. It provides theoretical basis for producing and using of the iron ladle and further optimal designing.

Introduction

Irom ladle applied to the molten iron of the iron and steel metallurgy field of logistics and transport for iron works, foundry use in blast furnaces, stoves, cast iron blast furnace to undertake the molten iron and blending, transshipment, casting operations, engaged in the transfer of molten iron peak production tasks, is the iron and steel metallurgy a high frequency of necessary equipment. Ladle refractory and shell, in which the refractory insulation from the main payload of the ladle shell suffered: the molten iron, refractory and shell gravity load and temperature load. The shell is the main load-bearing structures need to have sufficient stiffness and strength[1]. Existing large ladle largely based on the mechanical load, the use of elementary mechanics theory and the empirical coefficient for structural design calculations, the calculation accuracy can not meet the requirements of the modern iron and steel production[2]. Accurate 3-D stress and deformation of the structure has become a necessary precondition of large-scale the ladle structure design. 260t large ladle design research, consider the various stages of loading, a comprehensive analysis of the circumstances under load, to determine the most dangerous working conditions, using finite element program ANSYS for 260t iron ladle calculation, calculation of iron pitcher stress and deformation for 260t ladle steel strength and stiffness analysis.

The ladle structure introduced

260t iron ladle assembly ladle was shown in Fig.1. It composed of shell, lining, trunnion, base and so on. Tank shell adopted iron plate welding structure, the top was duckbill structure, the main structure was pyramid, the top outer diameter was 4615 mm, the bottom outer diameter was 4020 mm, wall thickness was 30mm, bottom thickness was 40 mm, height was 4600mm, internal depth was 4560 mm. The top thickness of the refractory material layer was 175.5 mm, the bottom thickness was 403mm, the inner bottom fillet radius was 750mm, and bottom thickness was 560 mm. The maximum volume of iron ladle was 260 t; there are 300 mm between liquid surface and

tank brim. The weight of shell was 33t, the weight of refractory material was 64t, the average temperature of the outer shell was 350°.Shell density was 7800kg/m^3, lined with refractory material density was 2800 kg/m^3, the molten iron density was 6800 kg/m^3, lined with refractory material elastic modulus of 40GPa, and Poisson's ratio was 0.3. The load of shell, the weight of the molten iron and the mechanical properties of the ladle shell were shown in Table 1.

Table.1 Ladle shell mechanical properties

Material	Elasticmodulu-s / GPa	Poisson's ratio	Strength limit / MPa	Yield limit / MPa	Allowable stress / MPa
20 g	203	0.3	410	235	100

Fig.1 Ladle shell structure

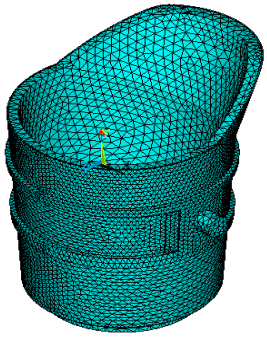

Fig.2 Finite element model of the iron ladle

Finite element mode

3-D model [3]of 260t iron ladle shell and lining were built using SolidWorks according to 2-D engineering drawings ,as shown in Fig.1.

Importing the shell and lining 3-D assembly model file into the finite element software ANSYS, and bonding the shell and lining, share the same side that is used to simulate contact with the inner surface of the shell and the outer surface of the lining. The type of grid was set. Shell, lining, trunnion and base were 3-D physical unit. Structural entity uses the Brick 8 node 45, the shell unit number 41545, the number of nodes 13935; lining unit number 50824, the node number 18949; local grid refining in the shell and trunnion contact area was carried on. Attach a shell and liner material properties and meshing [4,5]. In this paper, 3-D finite element algorithm was adopted to calculate the iron ladle shell and lining. The finite element model was shown in Fig. 2.

Imposed by the finite element model loads and constraints

The applied load.

loading in three conditions [6]:

(1)Working conditions of iron ladle in the hot metal tanker on standing;

(2)Working conditions of iron ladle trunnion lifting operation at full load;

(3)Working conditions of iron ladle pitcher tipping molten iron.

The shell blocked with lining as a whole. The densities of the shell and the lining are given, acceleration of gravity is 9.8m/s2. In variety of working conditions iron ladle shell structure dead weight and refractory material weight as volume force applied on tank.

Gravity reflected the side pressure of refractory layer and base pressure of lining bottom refractory layer. The distribution load of the molten iron weight applied on the tank side and bottom, the molten iron pressure on each inner surface increase with depth. Plane load was used; changing gradient is 66640N/m^2.

Impose constraints.

Iron ladle on vehicle in standing working conditions, trunnion hasn’t outside force, the full constraints applied to the contacting surface of the bottom of the iron ladle and car. Iron ladle operation conditions are, trunnion has tension of hoisting, Y and Z direction constraints were applied to the trunnion. Iron ladle out the hydraulic conditions, ladle tilt, and vertical angle of 30°, the applied load and constraint. Trunnion and turned molten iron rings at the upward lifting of tension therefore exert Y, Z direction constraints [6].

Analysis and Evaluation of calculation results

The equivalent stress of the structure was calculated according to Mises stress that is the fourth strength theory, the specific formula is

$$\sigma_d = \sqrt{\left[\left(\sigma_x-\sigma_y\right)^2+\left(\sigma_y-\sigma_z\right)^2+\left(\sigma_z-\sigma_x\right)^2+6\left(\tau_{xy}^2+\tau_{yz}^2+\tau_{xz}^2\right)\right]/2}$$

The maximum equivalent stress and maximum equivalent deformation of the various working conditions were analyzed by the output of nephogram and numerical analysis.

Working conditions of iron ladle in the hot metal tanker standing.

The load has been calculated considering the molten iron, refractory materials and shell weight. The overall stress of the iron ladle was shown in Fig.3, the deformation shown in Fig.4. The result shows the maximum stress is 28.9MPa in the upper edge of the shell; maximum deformation is 0.973mm in the duckbill.

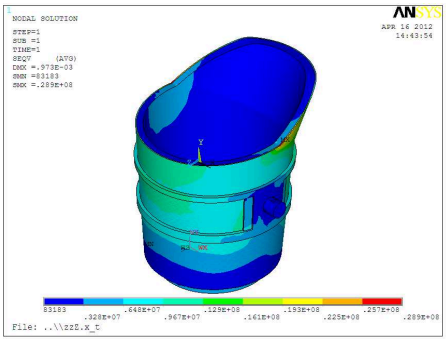

Fig.3 Stress in working condition 1

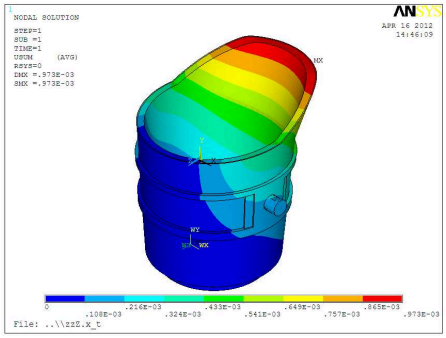

Fig.4 Deformation in working conditions

Working conditions of iron ladle lifting operation.

The overall stress of the iron ladle was shown in Fig.4, the deformation shown in Fig.5. The result shows the maximum stress is 93.4MPa around the trunnion; maximum deformation is 2.328mm in the upper edge of the duckbill.

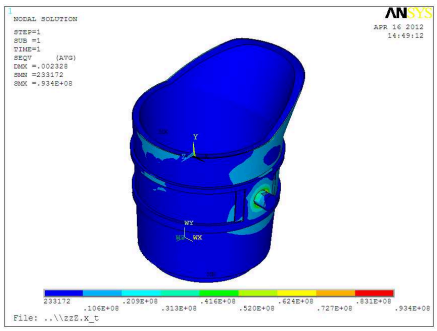

Fig.5 Stress in working condition 2

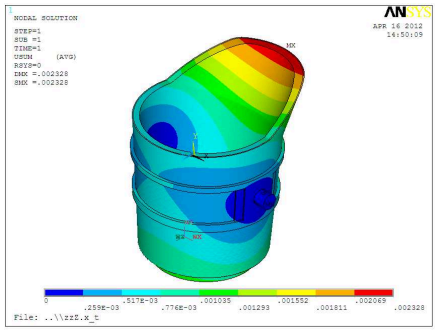

Fig. 6 Deformation in working conditions 2

Working conditions of tipping molten iron from iron tank.

The overall stress of the iron ladle was shown in Fig.7, the deformation shown in Fig.8. The result shows the maximum stress is 32.6MPa in the root of the trunnion; maximum deformation is 0.860mm in the upper brim of the ladle.

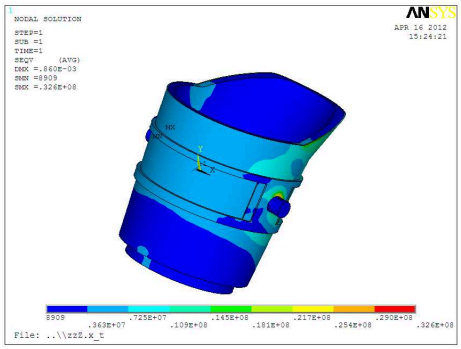

Fig.7 Stress in working condition3

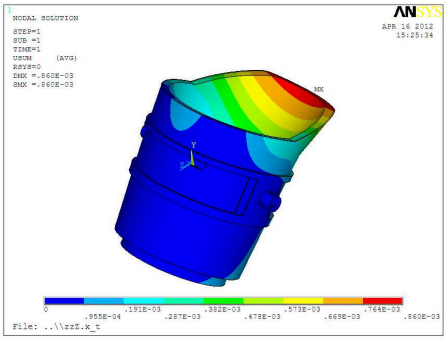

Fig.8 Deformation in working conditions 3

The iron ladle shell stress levels significantly higher than the stress level of the refractory layer from the nephogram of the iron ladle shell and lining surface stress field in Fig.3, Fig.5, Fig.7. The trunnion is the main and complicated loading structure. The higher stress distribution was shown around the trunnion. Ladle on strengthening rib stress, indicating the strengthening ribs strengthen the ladle shell. Analyzing the three cases, the maximum equivalent stress is less than the allowable stress of 100MPa, it meets the strength requirements. The maximum deformation is less than allowable deformation 5 mm; it also meets the stiffness requirements.

The results show that the full load of the iron ladle through the trunnion lifting operation in the most dangerous working conditions, strength and stiffness of the 260t iron ladle was sufficient .

Summary

(1)260t iron ladle has been under good conditions, and the deformation risk factors haven't existed yet through finite element analysis and design using ANSYS.

(2) It proves that the result of the analysis to the iron ladle using ANSYS accord with the actual stress. This method is reasonable and reliable. It will lay a foundation for checking and analyzing the iron ladle.

(3)More accurate calculation has been done to the iron ladle stress and deformation using three-dimensional finite element technique. The results provide a theoretical basis for the production and use of the iron ladle and further optimization of the design.

Keywords：rolling mill; natural frequency; finite element

Abstract：The vibration of the fifth frame mill of 1450 Cold Tandem Rolling Mill in the rolling process was studied using finite element software ANSYS. The dynamic analysis of one-piece frame and two- piece frame on the fifth frame mill were carried on. The natural frequency and mode of vibration were calculated. Through analyzing, we obtained that two- piece frame performed better.

Introduction

In the rolling process, shock vibration of the mill caused by biting steel and taking off the steel often lead to loosening of the anchor bolt，damage of the frame component and oscillation marks and so on, these will cause huge economic losses to enterprises. Therefore, in order to ensure the stability and enhance the plate quality, dynamic analysis of the rolling mill and controlling of their vibration characteristics were carried on in this paper [1, 2, 3].

Abnormal vibration phenomenon of the fifth frame mill of 1450 Cold Tandem Rolling Mill was studied in this paper; the vibration situations of one-piece frame and two-piece frame were analyzed. The natural frequency and mode of vibration were calculated and compared.

Model and Meshing

Some parts of the frame were simplified because calculating of the rolling frame was dynamic analysis rather than stiffness and strength. The finite element modal of one-piece frame and two-piece frame were built in ANSYS10.0 according to structural size of the mill frame [4].In order to ensure the accuracy of the calculating, 8-node solid 45 hexahedral element type of the entire structure was adopted. As the mesh density and mesh ways have small impact on the modal analysis results, free way mesh was used in this paper. Frame meshes were shown in Fig. 1 and Fig. 2.

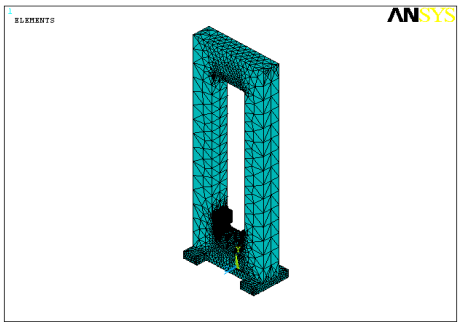

Fig.1 One-Piece Frame

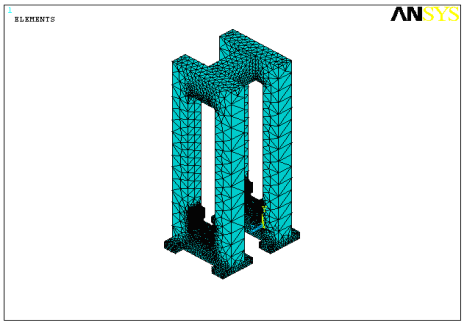

Fig.2 Two-Piece Frame

Modal Analysis

Using the above established frame finite element model, according to installation stress and rolling process stress, rigid constraints were imposed on the anchor bolt. The bottom surface of the left and right foot were imposed zero displacement constraints on X,Y, Z direction, respectively.

One-piece frame and two-piece frame natural frequencies were obtained , shown in Table 1 and Table 2.

TABLE.1 THE ONE-PIECE FRAME NATURAL FREQUENCIES

Order	1	2	3	4	5	6	7
Frequenc f_1 / Hz	8.21	17.02	35.95	55.95	81.56	85.63	96.14
Order	8	9	10	11	12	13	14
Frequenc f_1/ Hz	128.35	149.25	152.43	189.65	205.17	236.00	249.48

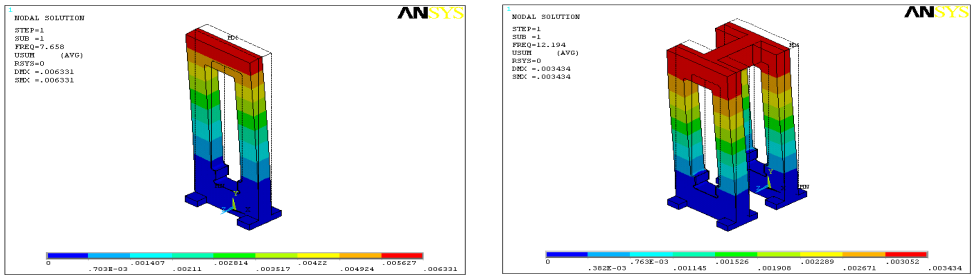

TABLE.2 THE TWO-PIECE FRAME NATURAL FREQUENCIES

Order	1	2	3	4	5	6	7
Frequenc f_2 / Hz	12.19	15.85	27.54	55.70	58.90	68.01	68.25
Order	8	9	10	11	12	13	14
Frequenc f_2/ Hz	80.88	82.55	92.77	94.31	106.69	123.72	133.88

Results Analysis

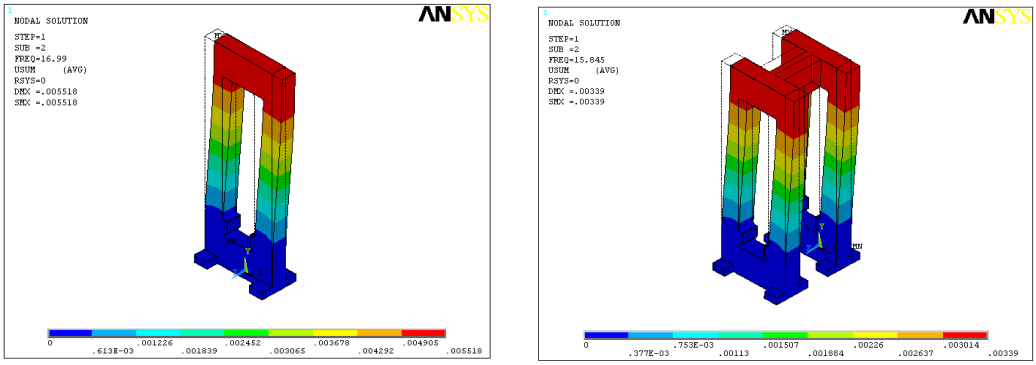
1st Order Mode

1st order modal shapes of one-piece frame and two-piece frame were shown in Fig.3 (a) and Fig.3 (b), respectively. In this natural frequency of the modal, vibration is most likely to occur. It can be seen from the figures, regardless of one-piece frame and two-piece frame, the vibration modes are rack along the swing before and after the roll axial direction. The top of the rack has the maximum deformation. According to Table 1 and Table 2, the 1st order natural frequency mode shape of one-piece frame is f_{101} = 8.21 Hz, and 1st order natural frequency mode shape of the two-piece frame is f_{201} = 12.19 Hz.

(a) One-Piece Frame (b) Two-Piece Frame

Fig.3 1st Order Mode Shapes

Comparison of two frequencies:



$$\alpha = \frac{8.21}{12.19} \times 100\% = 67.35\%$$

Conclusion: the coincidence rate was 67.35%, consistent with the 1st order natural frequency of the one-piece frame 8.21 Hz and two-piece frame 12.19 Hz. Both frequencies differ large, mainly due to two-piece chassis rigidity improved, leading to the increasing of vibration natural frequency.

2nd Order Modal

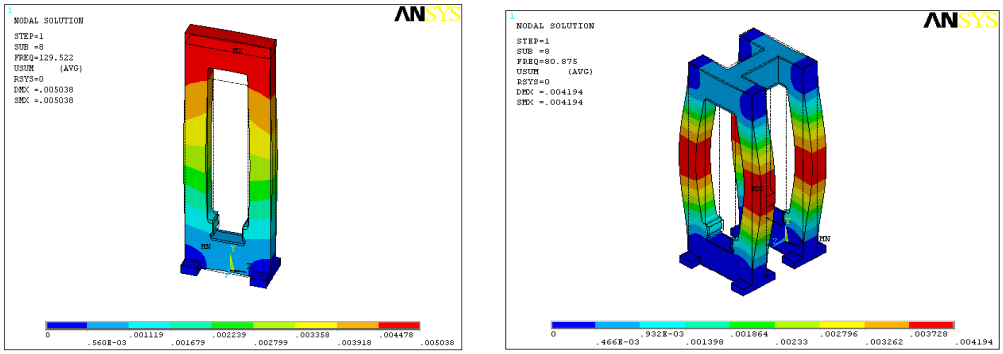
2nd order modal shapes of one-piece frame and two-piece frame were shown in Fig.4 (a) and Fig.4 (b), respectively. They are anti-symmetric modes. It can be seen from the figures regardless of one-piece frame or two-piece frame, the vibration modes are swing forward along the strip before and after. At the top of the frame deformation has maximum. However, according to Table 1 and

Table 2, the 2nd order natural frequency mode shapes of one-piece frame is f_{102} = 17.02Hz, and 2nd order natural frequency mode shapes of two-piece frame is f_{202} = 15.85Hz

(a) One-Piece Frame (b) Two-Piece Frame

Fig.4 2nd Order Mode Shapes

Comparison of two frequencies:



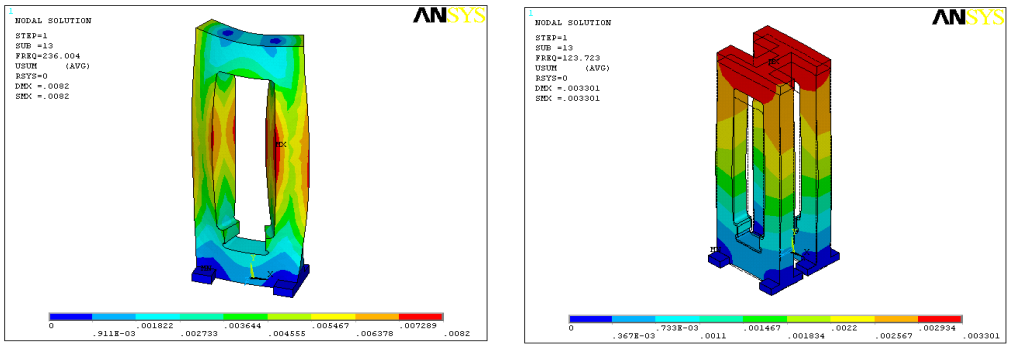
$$\alpha = \frac{15.85}{17.02} \times 100\% = 93.13\%$$

Conclusion: the coincidence rate was 93.13%, consistent with 2nd order natural frequency mode shapes of one-piece frame 17.02 Hz and 2nd order natural frequency mode shapes of two-piece frame 15.85 Hz, both frequencies are closer.

8th Order Modal

8th order modal shapes of one-piece frame and two-piece frame were shown in Fig.5 (a) and Fig.5 (b), respectively. It can be seen from the figures that one-piece frame mode shape is the vertical vibration mode shape; the two-piece frame is the symmetric mode shapes.According to Table 1 and Table 2, the 8th order natural frequency mode shapes of one-piece frame is F_{108} = 128.35Hz, and 8th order natural frequency mode shapes of two-piece frame is f_{208} = 80.88Hz.

Vibration modals are different, so they can not compare the frequencies of the matching rate.



(a) One-Piece Frame (b) Two-Piece Frame

Fig.5 8th Order Mode Shapes

13th Order Modal

13th order modal shapes of one-piece frame and two-piece frame were shown in Fig.6 (a) and Fig.6 (b), respectively. As can be seen from the figures, one-piece frame mode shape bending along the roll axial and two-piece frame is vertical mode. According to Table 1 and Table 2 shows, the 13th order natural frequency mode shapes of one-piece frame is f_{113}=236.00Hz, and 13th order natural frequency mode shapes of two-piece frame is f_{213} =123.72 Hz.

Vibration modes are not same, so they can not compare the frequencies of the coincidence rate.

(a) One-Piece Frame (b) Two-Piece Frame

Fig.6 13th Order Mode Shapes

Vertical Modal

One-piece frame and two-piece frame vertical modals are shown in Fig.5 (a) and Fig.6 (b), respectively. According to Table 1 and Table 2, the natural frequency are f_{108} =128.35 Hz and f_{213} =123.72 Hz.

Comparison of two frequencies:

$$\alpha = \frac{123.73}{128.35} \times 100\% = 96.4\%$$

Conclusion: from the consistent rate, the anastomosis of one-piece frame vertical natural frequency and two-piece frame vertical natural frequency is 96.4%, both frequencies are closer.

Summary

From the above analysis, we can conclude that modal analysis on two-piece frame did better than one-piece frame, and it obtained more real vibration model and more precise vibration frequencies. Therefore, the results of dynamic analysis on two-piece frame are closer to the real situations, it would be easier to solve vibration phenomenon appeared in the process of rolling process.

Keywords: thermal fatigue knowledge. ontology. super-hard cutting tools

Abstract: In order to reuse and share thermal fatigue knowledge, the thermal fatigue knowledge ontology is exploited. The basic ontology relationship and characteristics are analyzed and the concept classification and axiom are devised. With the help of Protege3.1.1 software, the thermal fatigue knowledge ontology comes into being. Based on the crack axiom, the intelligent matching of thermal fatigue crack states of super-hard cutting tools is accomplished.

Introduction

Ontology arises from the philosophy that deals with the nature of being. In such fields as knowledge engineering, natural language processing and intelligent information searching, ontology is the basis of formalization description, which may play the role of translation and mapping among different modeling tools, languages and software. When used in knowledge management, ontology is a glossary which is made up of concepts, axioms and rules. As a semantic model efficiently representing concept arrangements, its essence is reusing and sharing of knowledge.

On the other hand, ontology may provide advanced inter-operating utilities among different information systems, that is to say, the greatest contribution of ontology is that it can standardize concepts and terms in certain or many specialized fields, and make their applications easy to realize. Supported by the above mentioned justifications, the ontology application would improve the efficiency of knowledge searching, accumulating and sharing greatly and make it truly possible of knowledge reuse and sharing[1~3].

Concept Classification of Thermal Fatigue Knowledge Ontology

The concept classification is established in order to ascertain the main concepts, perform the collection and classification, and establish structure levels about thermal fatigue knowledge ontology. The first step is to build the thermal fatigue knowledge dictionary, which is a kind of professional one and aims at defining the domain nomenclatures and making clear its form and semantic. The needed knowledge may originate from experts, books, tables, networks, etc. The united domain dictionary would solve various understanding and settle the basis of field knowledge formalization.

The second step is to sum up the above nomenclatures into several super-species and make certain their suitable structure levels. In this paper, five species are gathered, including the component structure information, its material information, its working environment information, its states detecting information and cracks information, which corresponds to five sub-domain ontology separately, as shown in Fig.1.

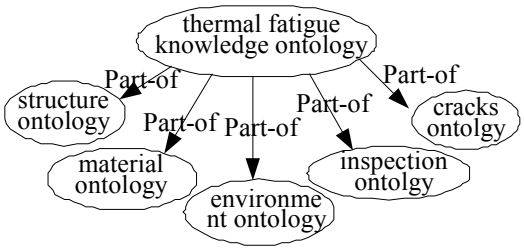

Fig.1 Five Sub-domain Ontology

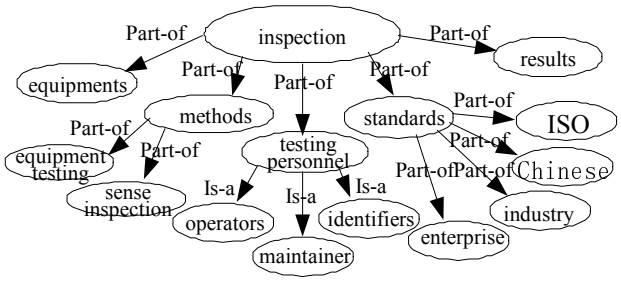

Fig.2 Components Inspection Ontology

Set-up of Sub-domain Ontology

Component Inspection Ontology

This ontology is designed to represent inspecting methods during machining processes, including testing standards, methods, equipments, testing personnel and results, etc. This sub-domain ontology is displayed in Fig.2.

Component Material Ontology

This ontology is applied to describe the component's property information as the material's constitutes and structure, heat treatment requirements, its mechanical and thermal properties, machinability, etc. This sub-domain ontology is indicated in Fig.3.

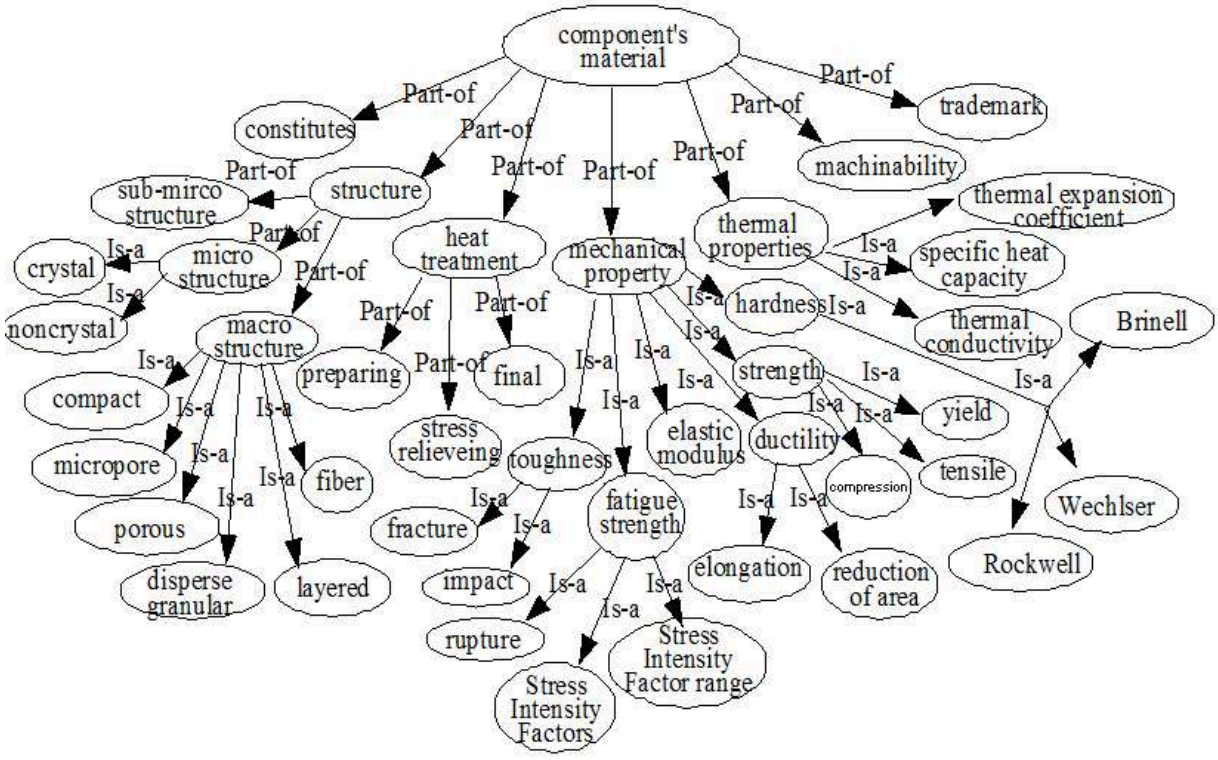

Fig.3 Components Material Ontology

Component Structure Ontology

It is used to depict the component's serial number, its roughcast type, its geometric characteristics, its machining process structure (including chamfer angle, chamfer circle, relief groove and grinding undercut, etc.), structural machinability, machining quality, etc. This sub-domain ontology is represented in Fig.4.

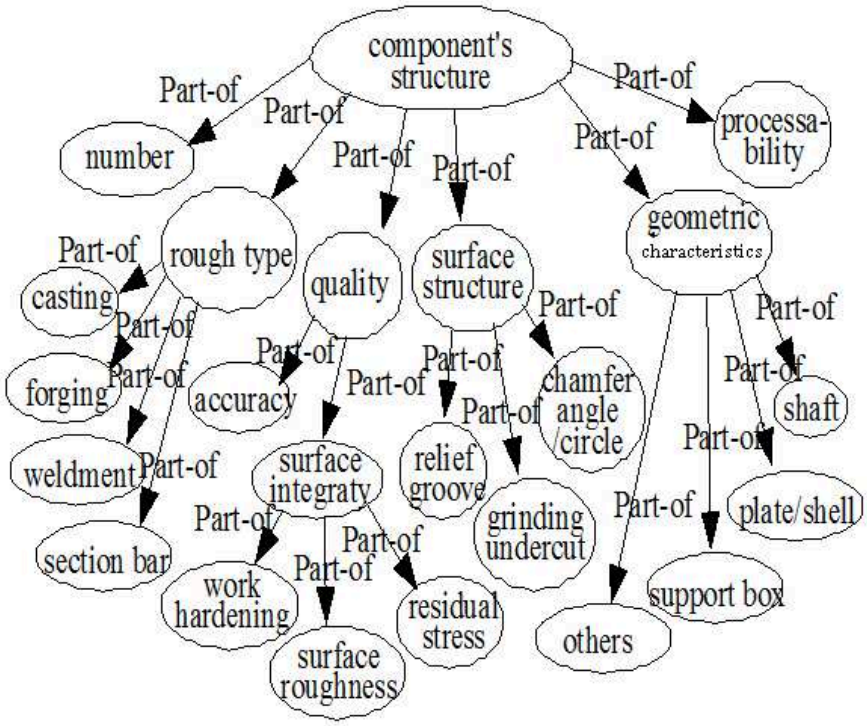

Fig.4 Components Structure Ontology

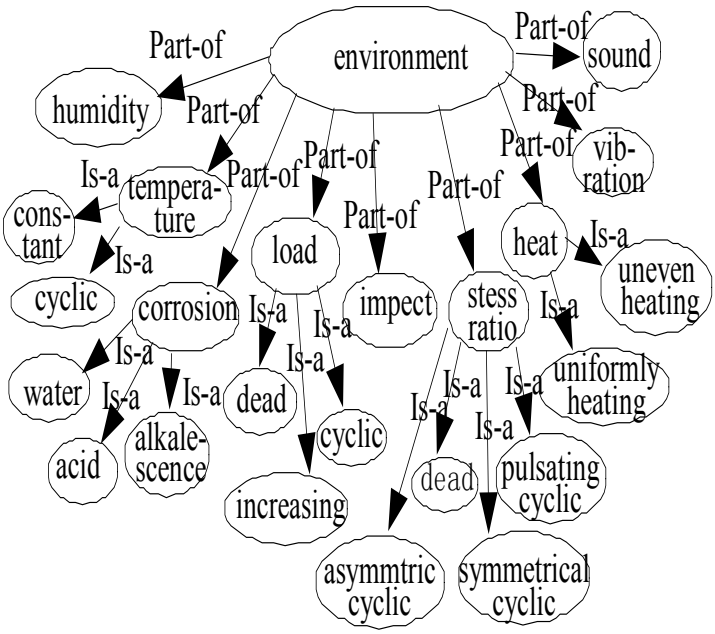

Fig.5 Components Environment Ontology

Component Environment Ontology

It is deployed to represent the component's working environment, including temperature, humidity, corrosion, load conditions, stress ratio, acoustic impulsion, vibration, and heat influence. This sub-domain ontology is displayed in Fig.5.

Component Cracks (Processes) Ontology

In the final analysis, failures of structures or components originated from cracks, which may be clear or obscure. Initiation and development of cracks dominate the failure processes, which may be classed into four phases, 1) changing of microstructures or substructures attributes to the permanent

damage contributing to micro-defects, 2) enlarging of micro-cracks or micro-pores forms dominant cracks, 3) dominant cracks propagate steadily, 4) structures lose stabilization or fail completely. Therefore, initiation, propagation and dominant cracks formation information should be included in the cracks ontology. This sub-domain ontology is shown in Fig.6.

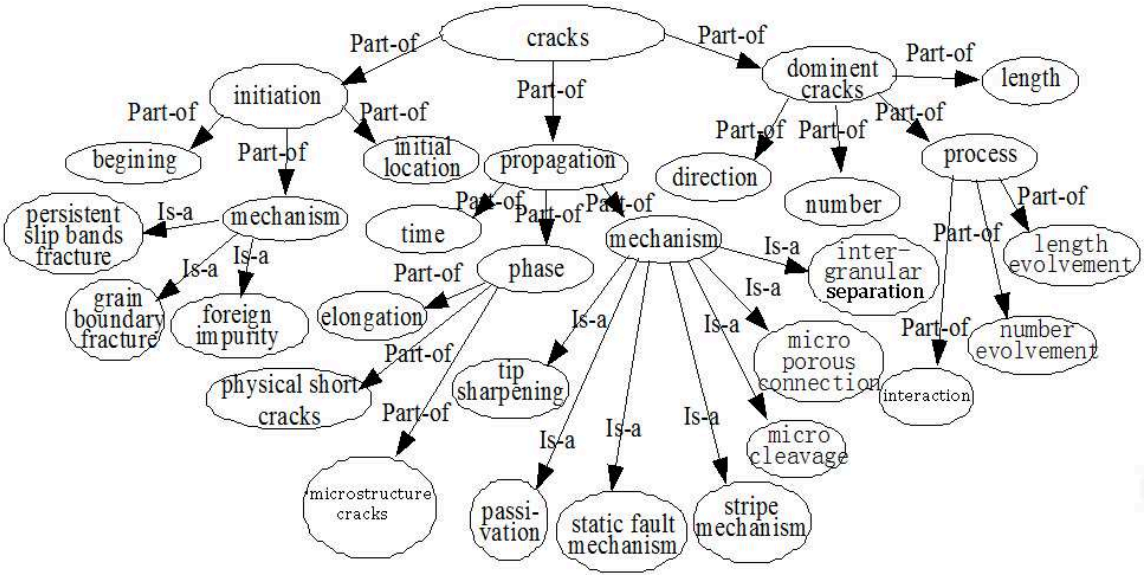

Fig.6 Components Cracks Ontology

Basic Relationships and Axioms Establishment

Some relationships may be applied all over the domain, not limited within certain single ontology, which possess several basic characteristics, as being symmetric, transferable, reverse, etc.

Basic relationships[4]

1) Inherited relationship, is-a.

Axiom 1: Relationship is-a is transferable.

Axiom 2: Relationship is-a is asymmetric.

2) Partial and whole relationship, part-of.

Axiom 3: Relationship part-of is transferable.

Axiom 4: Relationship part-of is asymmetric.

3) Case relationship, instance-of.

This one represents relationship between cases and concepts, similar to that between objects and kinds.

Basic Axioms

Besides some axioms shown above, there also exist axioms between top kinds and those belonging to sub-domains[5].

Temporary Conditions Axiom

$$(\forall a, \sigma_1, \sigma_2)\sigma_1 < do(a, \sigma_2) \rightarrow \sigma_1 \leq \sigma_2$$

$$(\forall a_1, a_2, \sigma)do(a_1, \sigma) = do(a_2, \sigma) \rightarrow a_1 = a_2$$

$$(\forall \sigma_1, \sigma_2)\sigma_1 < \sigma_2 \rightarrow \neg\sigma_2 < \sigma_1$$

Where a_i (i=1,2) stands for activities, σ_i(i=1,2)represents conditions, the function do(a, σ) represents what obtaining from carrying out the activity **a** under the condition $\boldsymbol{\sigma}$.

Axioms Applied in Sub-domains

After establishing axioms between top kinds, axioms used in sub-domains would be defined. For example, the crack axiom would be described as below, if a kind of crack state comes forth easily under certain machining condition, and this kind of condition does be detected in certain

manufacturing process, then it may be reckon that cracks appear in the component during this kind of machining process.

Ontology Realization

The Protege3.0 is a kind of developing tool based on Java designed by American Stanford University [4], supporting OWL(web ontology language), visual plug-in units and Chinese input. It possesses excellent ontology and knowledge base developing environments. With Protege3.1.1, ontology is displayed in tree like hierarchical directory structure and the domain model would be designed on the concept hierarchy, through adding or editing classes, sub-classes, attributes and cases by clicking the corresponding projects.

The crack ontology is set up and displayed in Fig.7.

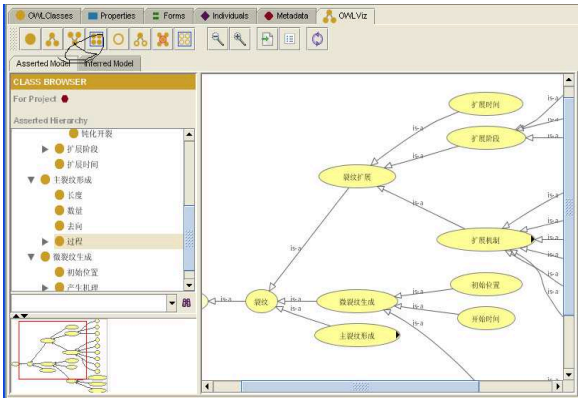

Fig.7 Crack Ontology Developed Through Protege3.1.1

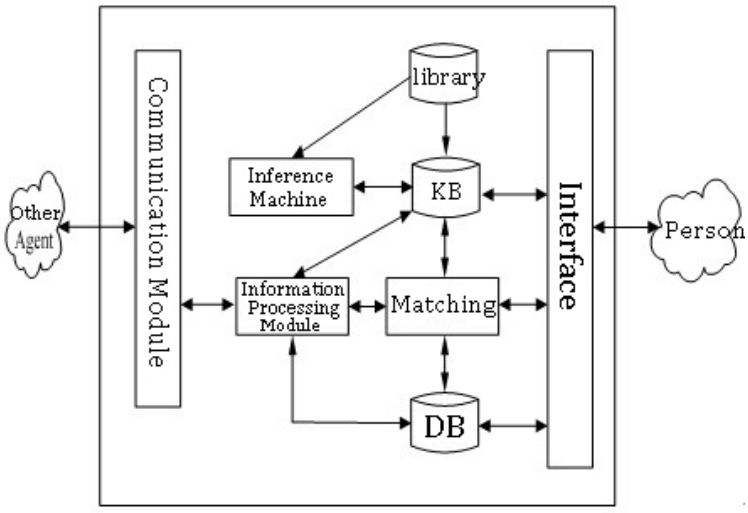

Fig.8 The Agent Structure

Ontology Applications

The Agent Structure

When the Agent technology is applied to thermal fatigue knowledge management, two problems must be solved. The first is how to represent ontology, the other is the disjoining of ontology with the knowledge describing information based on it. The sharing knowledge applied through fields is stored in ontology, which is the general understanding of various concepts and meanings and is hardly modified as soon as its establishment. If its modification is unavoidable, the ontology structure would not be changed as far as possible. While what be put in the knowledge base is practical cases and actual information existed in the present world, which should be changed and updated along with facts, so disjoining of them is necessary. In this paper, the Agent technology is used to realize the thermal fatigue knowledge management. Its schematic structure is shown in

Fig.8. This system consists of the following modules, as an information collecting and processing module, the decision-making module, the database, the ontology base, the learning and evolution module and the users interface.

Crack States Matching Evaluation

During high-speed milling processes, super-hard cutting tools are subjected to a hostile environment, where both heat and fluctuating forces act upon them. To get a full-scale of practical thermal fatigue crack states, multi-signals must be collected and analyzed because different signals have a variety degree of sensitivity. Under normal working conditions, values of all evaluation indexes, obtaining from practical measuring and relevant literatures[6], are displayed in Table 1.

Table 1 EVALUATION INDEX VALUES OF THERMAL CRACK STATES

Evaluation index （characteristic）	thermal fatigue crack rank			
	crack initiation	propagation	dominant crack formation	tools failure
Milling-force signal	80~90	90~100	100~105	105~115
Acoustic-emission signal	0~0.38	0.38~0.5	0.5~0.78	0.78~1.0
Vibration signal	0~0.35	0.35~0.48	0.48~0.83	0.83~1.0
Temperature signal	500~650	650~750	750~820	820~880

If the four evaluation values are 86, 0.28, 0.35, 590 respectively, it is known from Table 1 that this group value corresponds to the range of crack initiation. With the help of crack state evaluation axiom, it would be deduced that crack initiation has come into being in this cutting tool. Therefore, measures would be taken to avoid crack rapid propagation, such as introducing low cutting speed and low feed rate per teeth.

If there doesn't exist certain corresponding crack state in the knowledge base, the inference machine may reason by ontology axioms, then get the knowledge base updated and match using the matching module, finally return the result to users or certain relevant system.

Conclusions

The ontology model is proposed in this paper, together with the agent structure of thermal fatigue knowledge management. The crack state is intelligently evaluated and matched. This paper would help to promote the research on thermal fatigue cracks evaluation of super-hard cutting tools.

Void Formation and Growth at Solder-bonded Interfaces In HP LEDs

Wei Liu* and Peng Jin*

Peking University Shenzhen Graduate School

Room E-321A, University Town, Nanshan District

Shenzhen, P.R. China

weiliu@pkusz.edu.cn, jinpeng@pkusz.edu.cn

Keywords: high power LED PKG; solder-bonded interfaces; die-attach process; electrical stress; void

Abstract: Heat flux inside the HP LED chip is also increasing with the increasing drive current, integration and miniaturization of LED chips. The junction temperature of LED strongly depended on the heat transmission capacity of die attach layer, which provided the heat dissipation channel between the heat generating LED chips and the heat slug. The voids, interrmetallic compounds or a small delamination would lead to the increasing thermal resistance in the die attach layer. In this paper, the reliability of soldered-bonded interfaces was studied in high-brightness LEDs, which were prepared by Cree and currently available on the market. Results revealed that the higher drive currents would lead to the accelerated degradation or failure of treated LEDs. Additionally, the injection current had an important effect on void formation and growth at the solder-bonded interfaces. The larger drive current would induce the delamination between LED die and heat slug. This study provided some guidance for the end users and a theoretical basis for solder-bonded technologies.

Introduction

Since LED was first available in the 1960s, the efficiency and brightness have been rapidly increased by using new materials and new processes [1]. It is well known that LED has so many superior characteristics such as higher efficiency, lower power consumption, longer life, ultra-high-speed response time, controllable color temperature and so on. Currently, LEDs have acquired wider applications in automotive front lighting, backlighting for large LCD displays and city improvement engineering. And high-power LEDs are expected to substitute the traditional lightings. [2, 3]

However, for power and high-power LED devices, heat flux inside the chip is larger. If the heat generated in the chip could not be transferred instantly to the heat sink, the higher junction temperature would reduce light output, change color temperature and forward voltage, and decrease the service lifetime [4]. As we all know, LED chip is mounted on a heat sink. The die-attach materials and processes played a key role in the heat dissipation of LED chips [5, 6]. Traditionally, LED chip is mounted on a heat sink by silver paste, which has a poor capacity of heat transmission and could not meet the needs of high-power LEDs' heat dissipation [7, 8]. At present, solder alloys have been employed to achieve the solder joint between LED chip and heat sink. Cree, the leader in the LED industry, has declared that the value of thermal resistance was lower to 2.5K/W and the void ratio was even less than 5%. However, few interrelated research achievements about the solder-bonded technologies have been reported in the literature.

In this paper, the reliability of solder-bonded technology was investigated in the high-brightness LED components, which were commercially available in the market and prepared by Cree. The interfacial failure features were revealed and the corresponding failure mechanisms were discussed. This study would provide some basic data as well as a theoretical basis for die-bonding technologies.

Experiments

The treated components were high-brightness white LEDs produced by Cree, as shown in Fig. 1. The product information came from the Cree's official website. The LED chip was attached to a heat slug by solder joint. The value of thermal resistance is less than 5K/W and the void ratio is lower than 5%.

All the tested LED components prepared by Cree have been mounted on the hexagonal aluminum substrate by the manufacturer. The tested samples were aged by using the SSP3516-A high power LED aging test machine from Hangzhou Star Spectrum Photoelectric Technology Co., Ltd. The injection currents of 350mA, 750mA, 1000mA and 2000mA were adopted and the ambient temperature was maintained at 25℃. The luminous flux, luminous efficacy, color temperature and color rendering index were measured by Spec300 LED photoelectric integrated test system. These data were separately recorded after the samples were aged for 30 days, 60 days, 90 days, 120 days, 150 days and 180 days. After aged for 180 days, the tested components were mounted in epoxy and metallurgically polished. The microstructure and voids at solder joints was observed and analyzed by using a scanning electron microscope (SEM).

Fig. 1 Optical picture of the tested LED component prepared by Cree

Results and discussions

Fig. 2 showed the luminous flux changed with the aging time under the different injection currents of 350mA, 750mA, 1000mA with the ambient temperature of 25℃. It was indicated that the average value of luminous flux degraded by about 5% under the injection current of 1000mA after 180 days (4320h). Under electric stresses of 350mA and 750mA, the luminous flux degraded relatively slowly by the average value of about 3%.

Under the injection current of 2000mA, all the tested LED components could not be lit up within 48 hours. In fact, the temperature of the hexagonal aluminum substrate was very high, and the encapsulant became black and the carbonization occurred. Moreover, the optical lens was easy to fell off the heat sink. When the higher drive current of 2000mA was applied, a large amount of heat was generated inside the LED chip. If the generated heat could not be spread out instantly, the junction temperature of LED chip would be very high. Just as reported, the higher electrical stress and extreme thermal shock would induce the catastrophic failure of LEDs [9].

Fig. 3 showed the color temperature of the treated LEDs changed with the aging time under the different injection currents of 350mA, 750mA, 1000mA with the ambient temperature of 25℃. It was indicated that the color temperature almost had no change under the condition of 350mA/25℃. However, the values of color temperature under the injection currents of 750mA and 1000mA had changed even by 10%, far beyond the scope of 50K-100K human eyes could distinguish color difference.

Fig. 4 showed the cross-sectional SEM images of solder joint in the tested components aged with the different injection currents. It was obvious that the voids had been formed at the solder-bonded interface at the injection current of 350mA, as shown in Fig. 4a. With the increasing injection current (700mA and 1000mA), larger voids were observed at the solder-bonded interfaces (Fig. 4b and c). Fig. 4d indicated the cross-sectional SEM images of solder joint in the LED component tested under the injection current of 2000mA, which failed within 24 hours. It was found that even the

delamination had occurred at the solder-bonded interface. From above, it was concluded that the electrical stress played a key role in the void formation and growth.

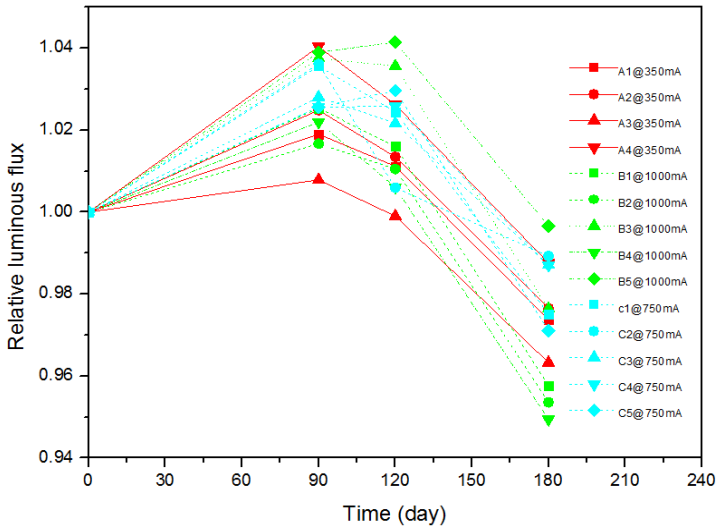

Fig.2. Relative luminous flux as a function of aging time under the various currents

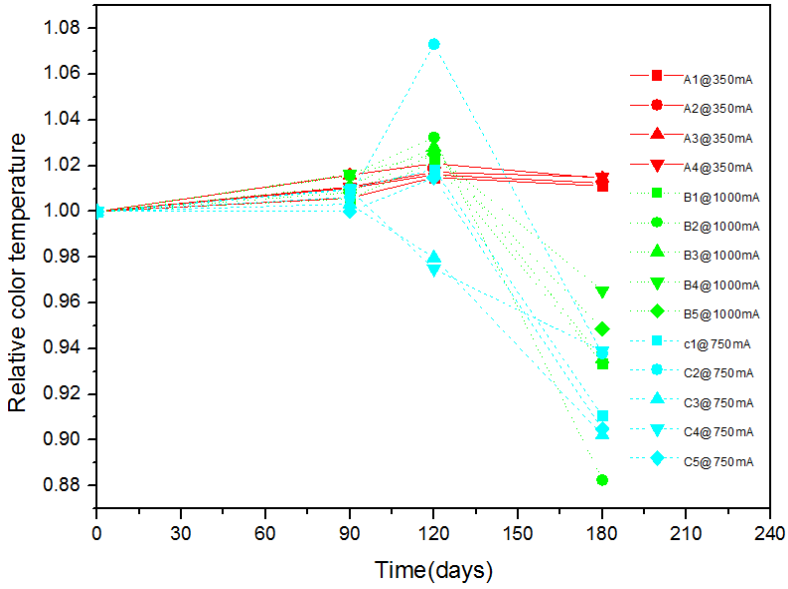

Fig.3 Relative color temperature as a function of aging time

It is well known that Cree has declared that its high-brightness LED component could offer the ultra-low thermal resistance down to 2.5K/W and its solder-bonded interface almost remained void-free. Surprisingly, after the LED components were aged, voids formed and grew at the solder-bonded interfaces and even the delamination occurred between LED die and heat slug.

Just as reported, any void or a small delamination would cause the instant temperature rising in the die, decreasing the internal quantum efficiency of LED chip. Additionally, the higher junction temperature would also deteriorate the conversion efficiency of the phosphor, and light extraction efficiency of silicon lens. [10] So, it was easy to understand why the luminous flux degraded by about 5% under the injection current of 1000mA and the values of color temperature under the injection currents of 750mA and 1000mA had changed even by 10%, just as shown in Fig 2 and 3. Especially, in Fig. 5 the larger delamination had occurred between LED die and heat slug, resulting in that the treated LED components could not be lit up again. It was concluded that under the electrical stress and thermal stress, voids would form and grow at the solder-bonded interfaces. This indicated strong

physical and chemical reactions had happened at the solder joints. Void formation and growth mechanisms would be discussed in another paper.

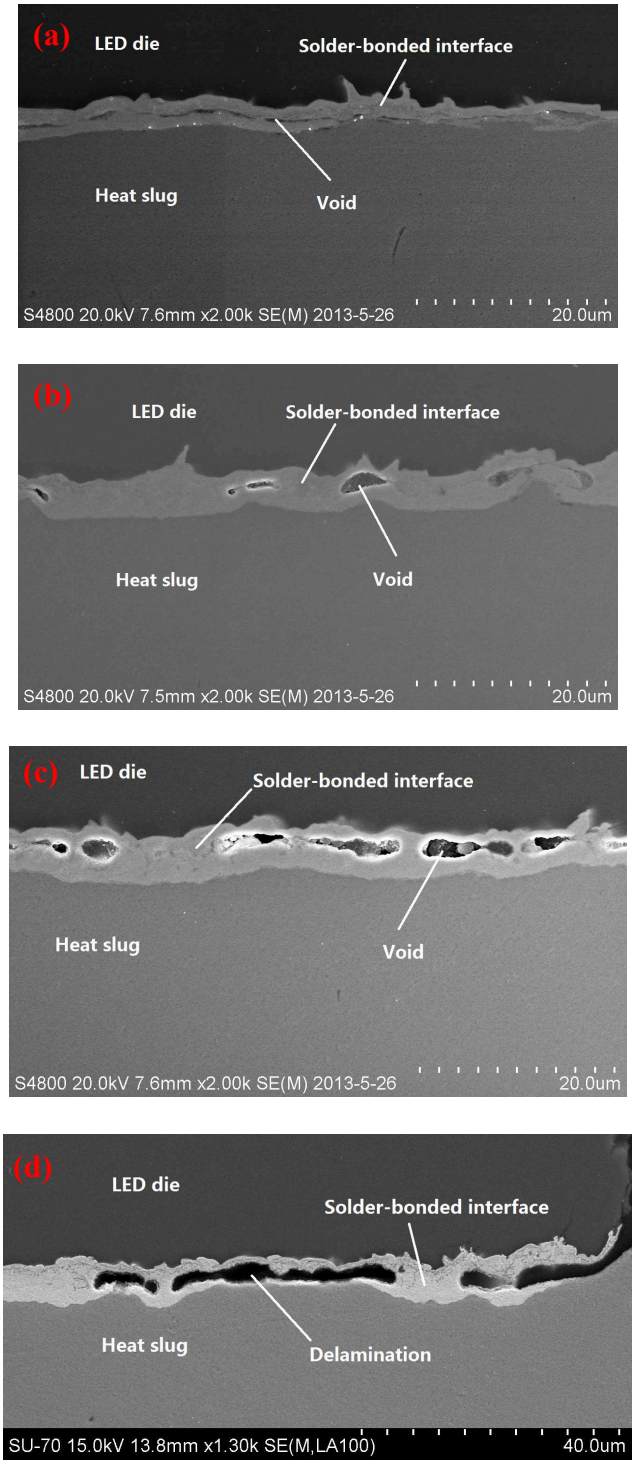

Fig.4 SEM images of solder-bonded interfaces after aging:

(a) 350mA,180days; (b) 750mA,180day; (c) 1000mA,180day; (d) 2000mA,2days.

Summary

In this study, high-brightness white LEDs from Cree were aged under various injection currents. Consequently, at 350mA the tested LEDs had a good performance. However at 750mA &1000mA the tested LEDs had a significant degradation and at 2000mA the treated LEDs could not illuminate within 24 hours. It was concluded that the higher drive current would reduce the reliability of LEDs

and shorten the service lifetime. It was interesting to find that voids would form and grow at the solder-bonded interfaces during aging. Moreover, higher currents would induce the number and size of voids increasing. At 2000mA, the delamination even occurred between LED die and heat slug. The die-attach quality played a key role in the heat transmission of LED. Any void or a small delamination would cause the instant temperature increasing in the die, leading to the degradation or failure of high power LEDs.

Keywords: super-hard cutting tools. thermal fatigue cracks. matter-element model

Abstract: A monitoring system is set up to get the machining process where super-hard cutting tools are used under surveillance. Signals such as the milling force signal, the acoustic emission signal, the vibration signal and the temperature signal are all collected to reflect tools practical conditions. Based on the extension theory, the partial-field matter-element, the full-field matter-element and the awaiting one are formed to evaluate the thermal fatigue crack states with the help of the relating function and the relating degree equation. Results show that this method is very reasonable and practical.

Introduction

While milling processes going on, where interrupted cutting takes place, subjecting super-hard cutting tools to a variety of hostile conditions, such as cyclic loading and alternately heating and cooling, all of these factors attribute to fluctuating thermal stress and strain, and finally thermal fatigue fractures, which result in tools failure and shorter tool life.

Small or micro, clear or obscure cracks contributed to thermal fatigue fractures of super-hard cutting tools [1~5]. Researches on variety states of thermal cracks, including its initiation, join or propagation, dominant crack appearance, may help the real-time identifying of thermal fatigue crack conditions of super-hard cutting tools.

A new multi-data quantitative decision-making method, the extension-element evaluation, is used to analyze thermal fatigue crack conditions of super-hard cutting tools, which unites qualitative and quantitative indexes effectively to make results reasonable and applicable.

Set-up of the thermal fatigue cracks identifying system

During machining, super-hard cutting tools are located in a hostile environment, where both heat and fluctuating forces act upon them. To get a full-scale of practical thermal fatigue crack conditions, multi-signals must be collected and analyzed because different signals have a variety of sensitivity degrees. The thermal fatigue cracks identifying system is established, as shown in Fig.1, sensors used including a force sensor, a acoustic emission sensor, a vibration sensor and a temperature recording sensor.

Signal collection is performed using the computer interface card, the infrared temperature measuring instrument, the SR150A acoustic emission sensor and the piezoelectricity acceleration instrument. On the Labview board, a front-panel, schematic programs and Ico /connection ports are deployed to realize virtual measurement. The CIN (Code Interface Node) technology is applied as the interface between Labview and C language to fulfill the following functions, as data collection, storing, evaluation and displaying.

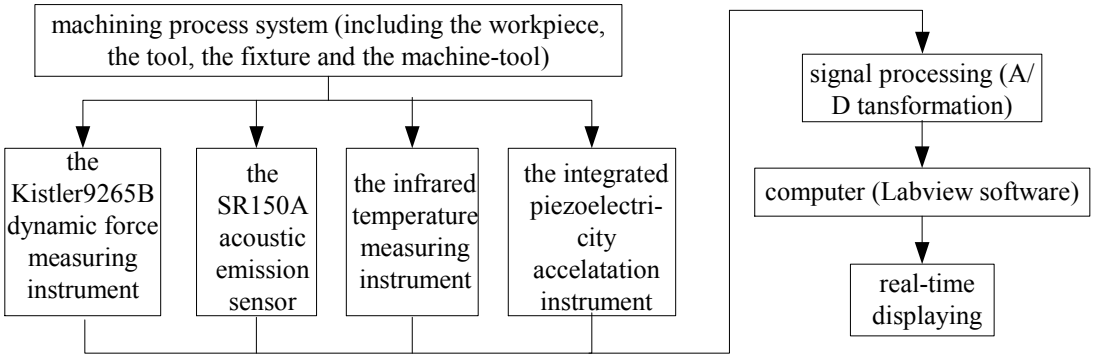

Fig. 1 The super-hard cutting tools thermal fatigue cracks identifying system

Milling-force signals

When milling at high cutting speeds, the milling-force is changeable in a dynamic pattern. In fact, tool teeth strike the workpiece in a cyclic style, corresponding to emergence of periodic impulse force acting upon it, that in turn results in vibration of the cutting tool and the workpiece. The above vibration also influences the milling depth which is what causes changing in the milling force. So the milling-force signal is used to vision the tools' thermal fatigue cracks conditions.

The Kistler9265B dynamic force instrument is used to measure the dynamic milling-force. Experiments indicate that when one of these parameters, the cutting speed, the feed rate per tooth, the radial cutting depth, changes respectively, the axial and perpendicular components of the milling-force, Fy and Fz ,remain almost unchanged, whilst only its radial component, Fx,changes prominently. So Fx is adopted to weigh the milling-force changing range.

Acoustic Emission Signals

Acoustic emission (AE) signal is a kind of elastic-stress wave originated from the release of elastic- transfiguration within materials. It appears from the cutting zone directly and is suitable for monitoring the thermal fatigue crack conditions due to its prominent properties of high frequency, fine sensitivity and rapid response. The SR150A acoustic emission sensor is adopted to measure the emission signals, which later is processed with the Matlab software. Thus the relationship between crack conditions and acoustic emission signals are established.

Vibration signals

Emergence of thermal fatigue cracks may directly affects the dynamic characteristics of machining processes, as well as the system arousing frequency and vibration swing. Therefore, through monitoring vibration signals, tools' thermal fatigue crack conditions would be informed exactly. An ICP (Integrated Circuits Piezoelectric) CA-YD-1182 type sensor is used to get vibration signals as the acceleration measuring is convenient and costless.

Temperature signals

When milling titanium alloys at high cutting speeds, because of small contact area between the cutting tool and the chip, the great stress acted on the tip and very low thermal conductivity of alloys, the cutting heat is too difficult to give out that local high temperature at cutting zone arises. Especially, when thermal fatigue fractures come into being, the attrition area between tools and workpieces enlarges, together with friction force increasing, all of which would result in prominent temperature raising. The manual thermo-electric couple method is applied to measure milling

temperatures and the wavelet transform method is adopted to deal with them. The results conform to regularity.

Evaluation process

Setting up of the matter-element mode

Information reflecting thermal fatigue crack states of super-hard cutting tools is denoted by the matter-element [6]. The following matter-element matrix R is called the awaiting matter-element, expressed as

$$R=\begin{bmatrix} p_0 & c_1 & X_1 \\ & c_2 & X_2 \\ & c_3 & X_3 \\ & c_4 & X_4 \end{bmatrix}$$

Where p_0 stands for a awaiting evaluation cutting tool; c_i（i=1~4）, properties of thermal fatigue crack states (N_{oj}), that is, the main factors affecting tools' thermal fatigue cracks, including milling force, acoustic emission, vibration and temperature; X_i is the practical measuring value of its corresponding affecting factor, c_i.

Partial and full field of matter-element model *R*

The partial field of R is shown below

$$R_{01}=\begin{bmatrix} \text{cracks initiation} & c_1 & 80\sim90 \\ & c_2 & 0\sim0.38 \\ & c_3 & 0\sim0.35 \\ & c_4 & 500\sim650 \end{bmatrix} \qquad R_{02}=\begin{bmatrix} \text{cracks propagation} & c_1 & 90\sim100 \\ & c_2 & 0.38\sim0.5 \\ & c_3 & 0.35\sim0.48 \\ & c_4 & 650\sim750 \end{bmatrix}$$

$$R_{03}=\begin{bmatrix} \text{dominant crack formation} & c_1 & 100\sim105 \\ & c_2 & 0.5\sim0.78 \\ & c_3 & 0.48\sim0.83 \\ & c_4 & 750\sim820 \end{bmatrix} \qquad R_{04}=\begin{bmatrix} \text{tools failure} & c_1 & 105\sim115 \\ & c_2 & 0.78\sim1.0 \\ & c_3 & 0.83\sim1.0 \\ & c_4 & 820\sim880 \end{bmatrix}$$

The full field of R is expressed as

$$R_P=\begin{bmatrix} P & c_1 & X_{P1} \\ & c_2 & X_{P2} \\ & c_3 & X_{P3} \\ & c_4 & X_{P4} \end{bmatrix}=\begin{bmatrix} P & c_1 & 80\sim115 \\ & c_2 & 0\sim1 \\ & c_3 & 0\sim1 \\ & c_4 & 500\sim880 \end{bmatrix}$$

Where P denotes all ranks of tools thermal fatigue crack states; X_{pi} stands for the actual value range corresponding to c_i, that is, the full field of P.

Determination of the awaiting matter-element

Under normal working conditions, measuring values of all characteristic indexes obtained through the thermal cracks monitoring system (Fig.1) are displayed in Table 1

TABLE 1 MEASURING VALUES OF THERMAL CRACK CHARACTERISTIC INDEXES

Evaluation index （characteristic）	thermal fatigue crack rank			
	crack initiation	propagation	dominant crack formation	tools failure
Milling-force signal	80~90	90~100	100~105	105~115
Acoustic-emission signal	0~0.38	0.38~0.5	0.5~0.78	0.78~1.0
Vibration signal	0~0.35	0.35~0.48	0.48~0.83	0.83~1.0
Temperature signal	500~650	650~750	750~820	820~880

The awaiting matter-element R is achieved as

$$R=\begin{bmatrix} p_0 & c_1 & u_1 \\ & c_2 & u_2 \\ & c_3 & u_3 \\ & c_4 & u_4 \end{bmatrix}$$

Where u_i (i=1~4) stands for the practical measuring values of evaluation indexes(milling force signal, acoustic emission signal, vibration signal and temperature signal), as shown in Table 1.

Foundation of the relating function

Based on the matter-element model, the relating degree between the cutting tool and its thermal fatigue crack states is got

$$K_j(u_i)=\begin{cases} \dfrac{-\rho(u_i,V_{0ji})}{|X_{0ji}|} & u_i \in V_{0ji} \\ \dfrac{\rho(u_i,V_{0ji})}{\rho(u_i,V_{pi})-\rho(u_i,V_{0ji})} & u_i \notin V_{0ji} \end{cases} .$$

Where $|V_{0ji}|=b_{0ji}-a_{0ji}$; $\rho(u_i,V_{0ji})=\left|u_i-\dfrac{a_{0ji}+b_{0ji}}{2}\right|-\dfrac{b_{0ji}-a_{0ji}}{2}$

$$\rho(u_i,V_{pi})=\left|u_i-\frac{a_{pi}+b_{pi}}{2}\right|-\frac{b_{pi}-a_{pi}}{2}$$

a_{0ji} is the minimum value of certain evaluation index in its partial field under its corresponding thermal crack condition; b_{0ji} the maximum value of certain evaluation index in its partial field under its corresponding thermal crack condition; a_{pi} the minimum value of certain evaluation index in its full field; b_{pi} the maximum value of certain evaluation index in its full field; α_i the power coefficient of certain selected index (milling force signals, acoustic emission signals, vibration signals and temperature signals), $\alpha=(\alpha_1, \alpha_2, \alpha_3, \alpha_4)=\{0.25,0.2,0.2,0.35\}$, $\alpha_1+\alpha_2+\alpha_3+\alpha_4=1$.

Therefore, the relating degree between the awaiting super-hard cutting tool p_0 and its certain thermal fatigue crack state is obtained. The equation is displayed below

$$K_j(p_0)=\sum_{i=1}^{4}\alpha_i K_j(u_i).$$

The value of relating degree $K_j(p_0)$ accords with certain thermal fatigue crack state. The bigger the higher corresponding degree, that is, $K_{j0}(p_0) = \max_{j0\in 1\sim 4} K_j(p_0)$.

Evaluation processes

Under certain milling conditions, and consulting relevant literature results, the measuring characteristics values are shown in Table 2. With the help of the relating function and the relating degree equation, results are got and displayed in Table 3.

TABLE 2 VALUES OF TESTING EVALUATION INDEXES

tools	milling-force signal	acoustic-emission signal	vibration signal	temperature signal
1	100	0.56	0.53	845
2	65	0.24	0.40	580
3	82	0.42	0.45	650
4	76	0.36	0.43	620

TABLE 3 EVALUATION OF THERMAL FATIGUE CRACK STATES OF SUPER-HARD CUTTING TOOLS

tools	$K_{10}(p_0)$	$K_{20}(p_0)$	$K_{30}(p_0)$	$K_{40}(p_0)$	evaluation results
1	−0.489	−0.299	−0.07	−0.119	normal
2	0.754	0.008	0.153	−1.191	dominant crack formation
3	−0.052	−0.21	−0.539	−0.661	normal
4	0.036	−0.452	−0.613	−0.674	crack initiation

Under normal cutting and testing conditions, the system where the whole evaluation process is embedded would automatically display the tools thermal fatigue crack states with the help of measuring evaluation indexes and distinguishing criteria. Experiments show that this method may be very reasonable and practical.

Conclusion

The tools' thermal fatigue fracture is a united consequence of cutting force and heat, whose evaluation and analysis are very complicated. Among so many affecting factors, some is suitable to be qualitatively analyzed, whilst others need quantitatively settled. Therefore, the extension theory is applied in order to obtain reasonable results through the combination of both qualitative and quantitative evaluation. This paper would provide a new effective method to access the thermal fatigue crack conditions of super-hard cutting tools.

Keywords: titanium alloys, texture, electron back scattered diffraction (EBSD), nanoindentation, electron beam welding, elastic modulus

Abstract: The microstructure, texture and elastic modulus of electron beam welding joint in Ti-6Al-4V titanium alloy were investigated by transmission electron microscopy, X-ray diffraction, electron back scattered diffraction and nanoindentation techniques. The α phase was in the majority, and a $\{0001\}\langle\bar{2}110\rangle$ texture of α phase was observed in the base material. A very weak $\{11\bar{2}3\}\langle\bar{1}\bar{1}22\rangle$ texture of α′ phase was in the fuse zone. Most of the α′ grain boundaries in the fuse zone were high-angle boundaries by electron backscattered diffraction, and it also confirmed that the orientations of α′ phase had a nearly random distribution in the fuse zone. The maximum average elastic modulus value measured by the nanoindentation techniques was in the base material due to the effect of the $\{0001\}\langle\bar{2}110\rangle$ texture. The average elastic moduli of three different zones in the joint were 134.8±3.5Gpa, 125.5±5.8Gpa and 123.0±4.7Gpa, respectively.

Introduction

Titanium alloys have been used in many fields of high performance applications. Hence, the processing of titanium alloys and the resulting microstructures and properties have received considerable attention [1, 2]. The textures or orientations in hexagonal-close-packed (HCP) materials could result in the strong mechanical and physical anisotropy [3–5]. The tensile strength, bend and fatigue responses in the transverse orientation were distinctly different from that in the longitudinal orientation due to the strong α-titanium texture [6]. The developments of microstructure and crystallographic texture were highly dependent on the method of joining the material as well as the subsequent processing steps. Several studies have investigated the evolution of microstructure and crystallographic texture of titanium alloys occurring in friction stir welding [7–10]. However, as an important fusion welding method of processing titanium alloys, electron beam welding (EBW) was distinguished from friction stir welding, which did not form the shear texture in the fuse zone (FZ). The solidification structure and microtexture in the FZ by gas tungsten arc welding were only investigated in two literatures [11, 12], and yet they focused on the effect of the heat input on the microtexture.

Elastic modulus (E) would play a critical role in determining the designs and the applications of the welded structures, so the research on the relation of the texture and elastic modulus was very essential. Nanoindentation provided an effective, non-destructive technique to measure mechanical properties such as elastic modulus or the hardness of local area and small volumes of materials [13, 14]. However, the developments of textures and elastic moduli in the whole joint of Ti-6Al-4V EBW, and as well as the connection between them, have not been examined in detail so far. For these reasons given above, the X-ray diffraction, electron backscattered diffraction (EBSD) techniques were employed in an attempt to provide the textures and orientations evolution in the joint of Ti-6Al-4V EBW. The nanoindentation technique was used to measure the Elastic moduli of different zones in the joint. The present study was also helpful in improving the basic physical understanding of mechanical behaviors of EBW joint in titanium alloys, such as the tensile and fatigue.

Experimental Procedures

The Ti-6Al-4V alloy used in this study was processed by unidirectional hot rolling in the (α+β) region, and it was supplied as a 21mm thick plate with no subsequent heat treatment. The base material (BM) had a chemical composition (wt. %) of 6.06 Al, 3.92 V, 0.3 Fe, 0.15 O, 0.0014 H, and balance Ti. A single pass, full-penetration, electron beam butt welding was performed perpendicular to the hot rolling direction (RD); hence the welded direction (WD) was parallel to the transverse direction (TD). The main welding parameters were an accelerated voltage of 150 kV, a focus current of 332 mA, an EB current of 28 mA, and a welding speed of 200 mm/min. A vacuum annealing at 600 °C for 4h was implemented to release the residual stress after EBW.

The samples were etched with a solution (HF:HNO3:H2O = 1:4:45) after being polished, and then the microstructure of the welded joint was observed by an Olympus optical microscope. After being removed from the FZ, the transmission electron microscopy (TEM) foils were electro-polished in a solution of 94% methanol and 6% perchloric acid at -30℃ with an applied voltage of 10V. The foils were then observed through TEM (Tecnai G2). The textures of the specimens were measured using D5000 x-ray diffraction goniometer based on Schulz reflection geometry. The crystallographic textures of the α phase in the BM and the α′ phase in the FZ were also shown, using three orthogonal pole figures {0002}, $\{11\bar{2}0\}$ and $\{10\bar{1}0\}$. A plan-view section in the FZ (RD-TD plane) was prepared for examination by electron backscatter diffraction (EBSD), and EBSD experiments were conducted in a Nano 400 field-emission scanning electron microscope equipped with the Channel 5 system. Nanoindentation experiments were conducted to evaluate the individual E values of the constituent phases: α and α′. These experiments were performed on a CSM nanoindentation instrument with a Berkovich tip. Maximum load was 10 mN, and the loading/unloading rates were 20 mN/min. The resulting load, P, vs. depth of indentation, h, curves were analyzed with the aid of the Oliver–Pharr method [15] to extract the E values.

Results

Microstructure and Texture

The base metal had a duplex microstructure that consisted of coarse equiaxed primary α grains in a transformed β matrix and secondary α laths separated by a thin layer of β phase (Fig. 1a). The equiaxed primary α grains tended also to be elongated along the hot-rolling direction. The cooling rate in EBW was high, and high cooling rate promoted the martensitic transformation [16–18]. The

coarse column β grains in the FZ were transformed into the aciculate α′ martensite below the transus temperature. Consequently, the FZ was mainly composed of aciculate α′ martensitic phase that formed a basket-weave microstructure, as shown in Fig. 1b. At very high magnification, the very fine β lamellar could be observed between the α′ martensitic laths (Fig. 1d). The heat affected zone (HAZ) showed a continuously transitional microstructure due to the temperature gradient, as shown in Fig. 1c. The HAZ near the BM contained many equiaxed grains, whereas the HAZ near the FZ formed many the aciculate α′ martensitic. The x-ray diffraction patterns of the BM and the FZ were shown in Fig. 2, it was further confirmed that almost the entire α′ martensitic phase was in the FZ.

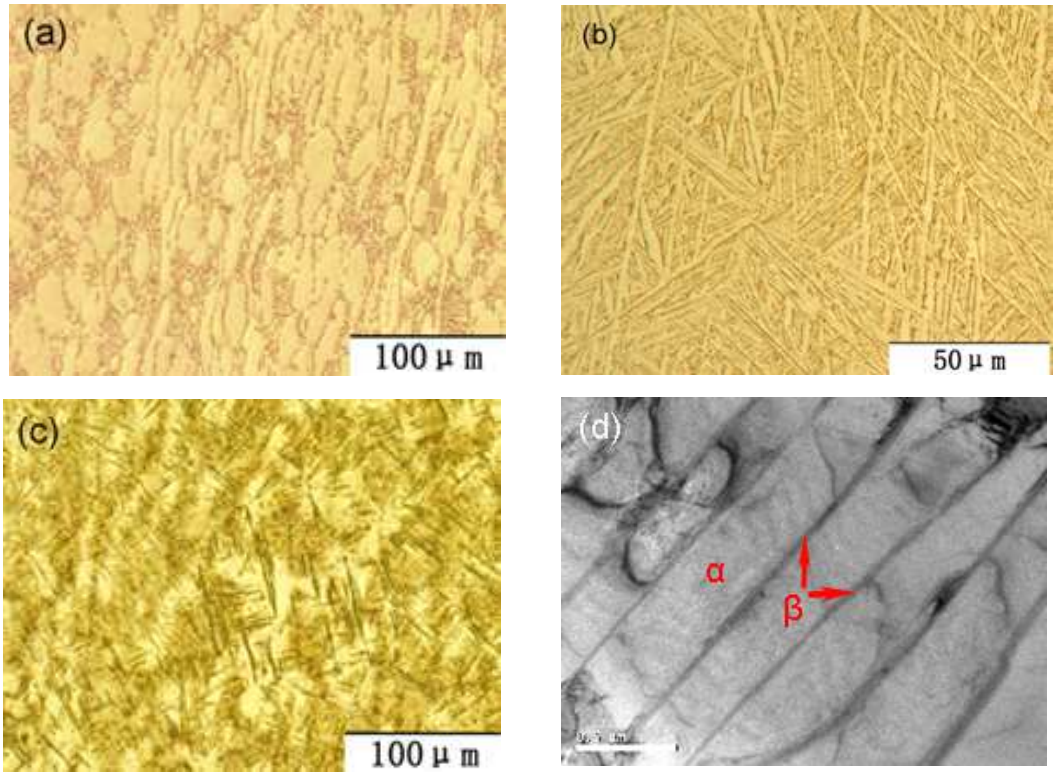

Fig. 1 Optical and TEM micrographs of Ti-6Al-4V EB-welded joint after post-weld vacuum anneal treatment: (**a**) BM, (**b**) FZ, (**c**) HAZ, (**d**) TEM micrograph of the FZ.

The β vol. % was approximately 18.5% in the BM, and the α phase was in the great majority. The microstructure was almost aciculate α′ martensite with a HCP structure in the FZ. For this reason, the textures of the two HCP phases were considered, and their textures were measured in the BM and the FZ. The {0002}, $\{\bar{2}110\}$ and $\{10\bar{1}0\}$ pole figures of the BM were shown in Fig. 3, two pole concentrations were observed in the normal direction (ND) and TD in Fig. 3a& 3b respectively, with the maximum intensity as 6.1 and 4.2. It indicated that a strong $\{0001\}<\bar{2}110>$ basal plane texture existed in the BM. The {0002}, $\{\bar{2}110\}$ and $\{10\bar{1}0\}$ pole figures of the FZ were shown in Fig. 4. The intensity of pole figures (Max: 2.1, 1.7 and 1.4) in the FZ subjected to the welding process was quite less when compared with the BM. It indicated there was a very weak $\{11\bar{2}3\}$ $<\bar{1}\bar{1}22>$ texture in the FZ, and the pole figures showed mainly the random spread of orientations in the FZ.

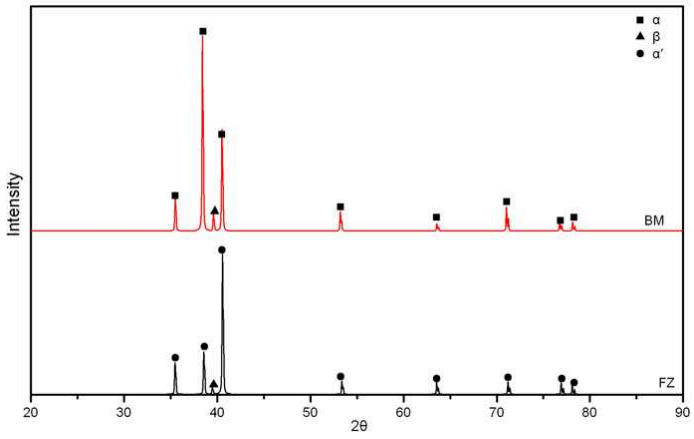

Fig. 2 X-ray diffraction patterns of the BM and the FZ.

▲ {11$\bar{2}$3} <$\bar{1}\bar{1}$22>

An EBSD map of the FZ was showed in Fig. 5, colored according to crystal orientations in the inverse pole figure. This EBSD map depicted the types of crystallographic plane that were aligned with the sample surface, i.e., RD-TD plane. The α′ laths were very thin, about 1~3μm; and 10~60μm in the length. Within each column prior β grain, there were a number of α′ laths with various orientations, which were shown in different colors. Some α′ laths within the colony shared a common crystallographic orientation, as indicated by mark A in Fig. 5. Low-angle boundaries (LABs) were depicted as black lines, and high-angle boundaries (HABs) as yellow lines (Fig. 5). Obviously, most of the grain boundaries were HABs and only sporadic LABs were interspersed within some grains.

Elastic Modulus

After the sample was finally prepared by mechanical and chemical polishing, ten indentation points were measured for the HCP phases in each zone. The average E value of α phase was 134.8±3.5Gpa in the BM, and the average E value of α′ phase was 123.0±4.7Gpa in the FZ. It contained two HCP phases in the HAZ: α and α′, and their volume fractions gradually varied in different positions. Consequently, the elastic moduli were composed of the E values of α and α′, and the average E value was 125.5±5.8Gpa in the HAZ. The average E values of HCP phases in three zones were given in the Table 1. The E could be derived from analyzing the load-displacement curve, and representative P–h curves obtained from the HCP phases of three zones in the joint are shown in Figure 6.

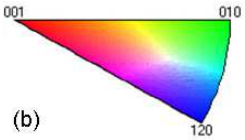

Fig. 5 (a) EBSD analysis of the α′ crystallographic directions (b) the color key was described in the inverse pole figure legend.

Discussion

The α laths formed in the β matrix were known to be oriented according to the Burgers orientation relationship: $\{110\}_\beta // \{0001\}_\alpha$, $<111>_\beta // <11\bar{2}0>_\alpha$. So the sharpening α′ texture could be inherited when the material underwent a cold rolling prior to the α→β→α′ transformation sequence, which depended on the deformation texture in the parent phase [19]. However, the α′ inherited orientations were almost randomly distributed in the FZ, because the β texture has been removed in the melted state during the welding process. For cubic β phase, the crystallographic direction favoring fastest growth was <100> direction, and the other two orthogonal axes could exist at any arbitrary rotation about the <100>axis. Hence, the prior β columnar grains in the FZ would be expected to have a $\{h\ k\ l\}$ <100 > fiber texture, and [100] crystal orientation was parallel to the RD. If so, the distribution of the maximum intensity points in $\{110\}_\beta$ pole figure would be shown as Fig. 7. According to the Burgers orientation relationship, so should be the similar maximum intensity distribution of $\{0001\}_\alpha$ pole figure. However, this case did not be observed in Fig. 4a. It suggested that the β grains did not form the strong $\{h\ k\ l\}$ <100> fiber texture during the solidification.

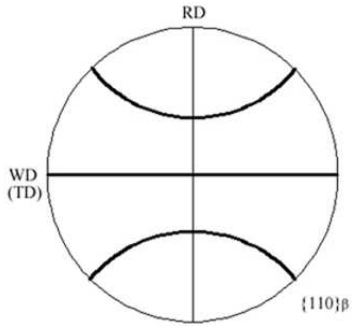

Fig. 7 The deduced distribution of intensity points in $\{110\}_\beta$ pole figure (as black bold lines), if the strong $\{h\ k\ l\}$ <100 > fiber texture could form in the FZ during the solidification

Due to the high cool rate in EBW, the growth of prior β grains were slower, but the nucleation more rapid, and so the preferential growth along <100> direction could not perform very well. Because of crystal symmetry, there were 12 distinct α orientation variants subjected to the Burgers relationship, which could form in a single parent β grain. For EBW, the high cool rate greatly promoted the homogeneous nucleation. As a result, many orientation variants could occur with

equal statistical probability during the β→α′ transformation in the FZ. Furthermore, an increase in the number of variants came with the increasing of the cooling rate [12, 20]. When two α′ laths or colonies with different variants adjoin in a prior β grain, a HAB would be formed, as shown in Fig. 5.

The strong anisotropy existed in the HCP Ti because of its lower crystal symmetry. Viswanathan et al. [21] have reported the hardness varied significantly with orientation. Near the [0001] stress axis, the hardness values were the highest, and the hardness values decrease as the stress axis deviates from near [0001] orientations. The values of indentation modulus measured by employing atomic force acoustic microscopy were 121.1GPa for $\{10\bar{1}0\}$, 142.7GPa for {0001}, and 130.3GPa for $\{10\bar{1}1\}$ [22]. These values matched quite well with the range of E values obtained from the present investigation. The indentation modulus of the α′ martensite is marginally lower than that of the α phase [22]. Hence, the mean E value of α phase in the BM was higher than that of α′ phase in the FZ, due mainly to the existence of the strong $\{0001\}<\bar{2}110>$ texture. The elastic and plastic strain fields around an indentation were very complicated. A given slip system depended on whether the value of the shear stress resolved on the system has exceeded its necessary critical resolved shear stress (CRSS). The CRSS in the basal slip system was much greater than in the prismatic and pyramidal slip systems [23]. Thus, when loading normally to the basal plane texture in the BM, the activation of slip systems was difficult. Consequently, the plastic deformation was difficult in the basal plane. Furthermore, the {0001} crystal plane was the strong close-packed plane. As a result, the maximum E value could be measured in the BM. The texture in the FZ was very weak, so the E was hardly influenced by the crystal orientations, and exhibited the mean value of random orientations. The average E value in the HAZ was between that of the BM and the FZ because of the effect of fractional basal <a> texture.

Conclusions

In this study, microstructure, texture and E developments in the EBW joint were investigated in Ti-6Al-4V titanium alloy. The α phase was in the great majority in the BM. A strong $\{0001\}<\bar{2}110>$ texture existed in the BM, as a result, the mean E value of HCP α phase in the BM was largest among three zones of the joint. Because of the high cool rate during the solidification and β →α′ transformation, the FZ was composed of aciculate α′ martensitic phase. It formed a very weak texture in the FZ, and most of grain boundaries were HABs. So the E value in the FZ represented the average value of random orientations. The HAZ between the BM and the FZ showed the characteristic of the transition zone, and had the moderate average E value.

Keywords: combined process “rolling-pressing”, equal-channel step matrix, grooved rolls, modelling, stress-strain state.

Abstract

In the development of new technology metal forming the main purpose is improvement the quality of the source material. The main aspect of quality improvement is increasing the strength characteristics. Often to increase the strength of deformable metal should be given reduced grain structure, up to subultra and even nano-level. There are several ways to obtain sub-ultra-fine-grain structure of metals, and one of those ways is a method of severe plastic deformation (SPD), implemented in the whole volume of the deformable metal.

In this work computer modeling was performed of the combined process "rolling-pressing" with the use of grooved rolls and equal channel step matrix with varying basic geometric and technological factors which have a significant impact on the process, what was made for the analysis of the impact of various factors on the stress-strain state of the process.

Introduction

In recent years a number of new processes of metal forming to obtain metal with sub-ultra-fine-grain structure were developed. One of the most promising, exceeding the previously known methods of metal forming, is a combined process of "rolling-pressing" with the use of grooved rolls and equal channel step matrix for pressing (Fig. 1), which was developed at the department "Plastic Metal Forming" of Karaganda State Industrial University [1]. The advantage of this process is that the implementation of the combined process ensures the continuity of the process and removes limits of size of initial workpiece.

The essence of this process consists in the fact that the billet pre-heated to the temperature of the beginning of deformation is fed to the rolls which grip it into the roll gap at the cost of contact friction forces and on leaving the roll gap they push it through the channels of the equichanneled step die. When the billet leaves the roll gap completely another billet is fed which having passed through the rolls and entering the die pushes out the previously deformed billet from the die. That means that in – this case the billet extrusion in the equichanneled step die is realized at the cost of using contact friction forces emerging on the surface of the contact of metal with the spinning rolls.

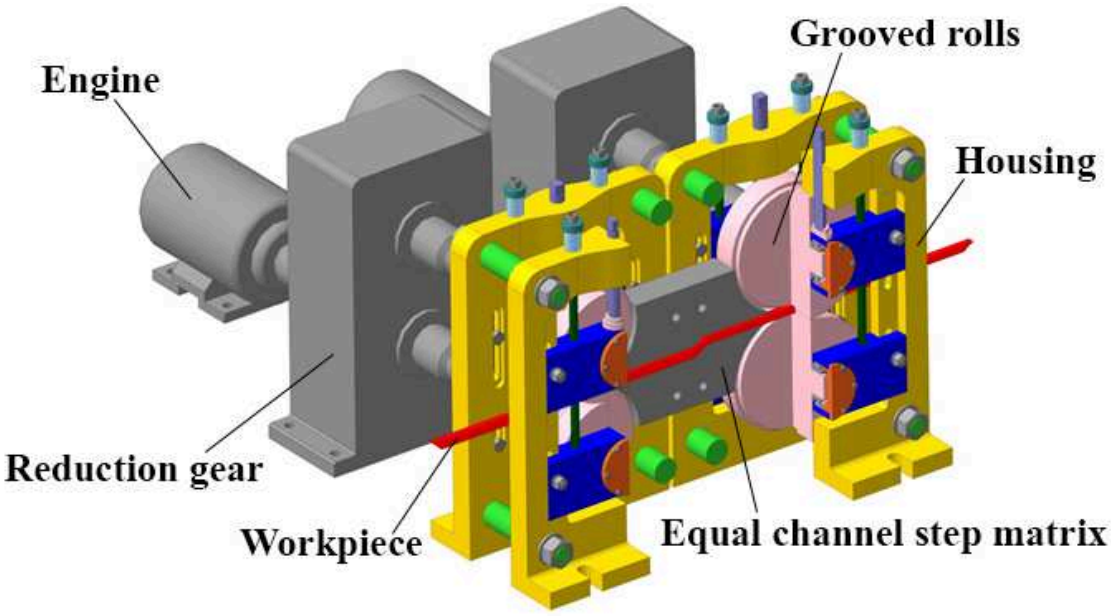

Figure 1 - Combined process of "rolling - pressing"

Investigation of stress-strain state

In the development of any process of metal forming study of stress-strain state is a critical step. The analysis of the strain state allows the examination of accumulated strain distribution throughout the volume of the workpiece during the deformation, to identify the areas that are more susceptible to deformation, and based on this define rational as geometric and technological parameters deformation and stress state of analysis allows to evaluate the voltage occurring at deformation and to identify the most dangerous areas, where possible tool breakage. Therefore, this paper deals with the influence of geometrical and technological factors on the stress-strain state (SSS) of the metal in the implementation of the combined process of rolling - pressing using equal channel step matrix and grooved rolls. To do this, it was decided that the variation of the basic geometrical and technological factors which have a significant impact on the process of rolling - pressing.

Study the impact of major technological and geometrical factors on the implementation of SSS metal combined process of "rolling-compression" using equal channel step matrix and grooved rolls made in the software package DEFORM-3D.

For a thorough study of the stress-strain state the following parameters were considered:

1) Strain Effective.
2) Stress Effective

In the course of previous studies [2], it was discovered that the main geometrical and technological factors that have a significant impact on the combined process of "rolling- pressing ", are following:

- the radii of the first and second pairs of rolls R_1 and R_2, mm;
- Angle of joint channels in the matrix φ, deg;
- absolute reduction Δh, mm;
- length of first and second channels in the matrix L_1 and L_2, mm;
- coefficients of friction in rolls and matrix μ_1 and μ_2;
- temperature of the billet.

However, as noted in work [3], the selection of the optimum geometry and process parameters is critical to the very possibility of the implementation of the "rolling - pressing" in the grooved rolls. And the wrong choice of at least one of the parameters can lead to a denial of the process. Therefore, it was decided to carry out the variation within the acceptable range for each parameter. Also, you need to provide the "reality" of variation, ie, exercise varying the factors which may change the parameters in real terms. Change the values of the radii of the first and a second pair of

rolls is irrational because to install the new roll is necessary to create new designs of stand. Vary the size of the coefficient of friction in the rolls is also unreasonable, because the recommended value for this parameter is the maximum (μ_1 = 0,5). Rotational speeds of the first and second pair of rolls can be varied, but only in a certain ratio, in disassembled [4]. Otherwise, the workpiece will not be captured by the second pair of rolls.

The base model is modeled, constructed in work [3]. The parameters of this model are following:

Table 1 – Parameters of the base model

Cross-section of the billet after deformation $h_1 \times b_1$, [mm]	Parameters								
	R, [mm]	μ_1	l_1, [mm]	l_2, [mm]	Δ h, [mm]	μ_2	φ, [deg]	$\sigma_т$, [MPa]	R_2, [mm]
40 x 60	250	0,1	40	30	15	0,5	140	40	280

The initial billet had its original size h_0 x b_0 x l_0 = 55 x 35 x 200 mm. As the material of the workpiece has been selected steel 35 heated to a temperature of 1100 °C.

Since the implementation of the process necessary for compliance with the conditions $P_{ROLL} > P_{PRESS}$, so for modeling were taken the following coefficients of friction:

- in rolls – 0,5 – for maximum P_{ROLL};
- in matrix – 0,1 – for minimum P_{PRESS}.

For varying the geometry and process parameters have been set up additional models with the following factors changes:

- Angle of joint channels in the matrix φ=145°, φ=150°;
- length of first channel in the matrix L_1=35 mm, L_1=30 mm;
- length of second channel in the matrix L_2=25 mm, L_2=20 mm;
- absolute reduction Δh =18 mm, Δh =20 mm;
- coefficient of friction in matrix μ_2=0,08, μ_2=0,05;
- temperature of the billet t=1200 °C, t=1000 °C.

Since almost all parameters are only to varying matrix, in the study of SSS it was decided to analyze the deformation of the next stage: the workpiece is rolled in the first pair of rolls, passes through the channels of the matrix, and then rolled to the second pair of rolls. At this stage it is possible to study the SSS in the matrix, and both pairs of rolls.

a) Basic model

In the implementation of the "rolling-pressing" billet passes through three stages of accumulation of plastic strain (Fig. 2):

Stage 1 - after rolling billets in the first pair of rollers - the value of equivalent strain ε_{eqv} is 0 ÷ 0,617;

Stage 2 - after overcoming a sloping channel in the matrix - the value of equivalent strain ε_{eqv} is 0,617 ÷ 1,33;

Stage 3 - After rolling billets in the second pair of rolls - the value of equivalent strain ε_{eqv} is 1,33 ÷ 2,0.

Accordingly, when implementing the "rolling-pressing" occurs three zones of deformation (Fig. 3): in the first and second pairs of rolls, and at the junction of the channels in the matrix. The average value of the stress is 70-85 MPa, maximum value is 118 MPa.

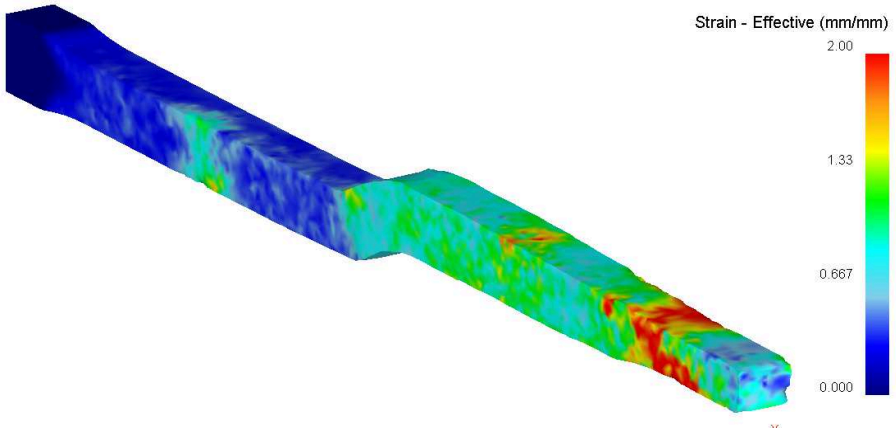

Figure 2 - Distribution of equivalent strain ε_{eqv}

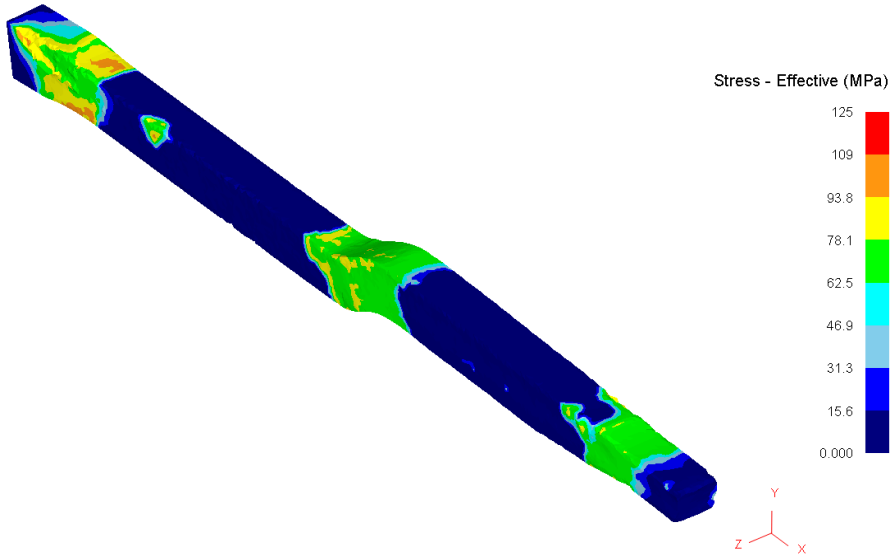

Figure 3 - Distribution of the equivalent stress σ_{eqv}

b) The model with the angle of the junction of channels 145°

When using a speed equal channel matrix with an increased angle of the joint channel intensity of the accumulation of plastic deformation is reduced by reducing the back pressure force. This occurs in the second and third stages, whereas the first stage ε_{eqv} value is not changed.

On the 1st stage the value ε_{eqv} is 0 ÷ 0,617;

On the 2nd stage the value of ε_{eqv} is 0,617 ÷ 1,27;

On the 3rd stage the value of ε_{eqv} is 1,27 ÷ 1,9.

The equivalent stress is also reduced by reducing the back pressure force. The average value of the equivalent stress is 70-75 MPa and 110 MPa maximum.

c) The model with the angle of the junction of channels 150°

Similarly the model with the angle of the junction of channels 145°, using a step equal channel matrix with the angle of the junction of channels 150° rate of accumulation of plastic deformation is reduced by reducing the back pressure force.

On the 1st stage the value ε_{eqv} is 0 ÷ 0,617;

On the 2nd stage the value of ε_{eqv} is 0,617 ÷ 1,21;

On the 3rd stage the value of ε_{eqv} is 1,21 ÷ 1,85.

The equivalent stress as the previous model is also reduced by reducing the counter force. The average value of the equivalent stress is 60-70 MPa and 98 MPa maximum.

d) Models with a length of the first channel in the matrix L_1=35 mm and L_1=30 mm.

In studying these models, it was noted that the distribution of stresses and strains throughout of the workpiece with change of length of the first channel in the matrix is not changed.

e) Models with a length of the second channel in the matrix L_2=25 mm.

When studying the model with the reduced length of the second channel in matrix L_2 = 25 mm, it was noted that the value of the equivalent strain decreases in the 2nd and 3rd stages of the process. At the first stage of the value of ε_{eqv} remains unchanged.

On the 1st stage the value ε_{eqv} is 0 ÷ 0,617;

On the 2nd stage the value of ε_{eqv} is 0,617 ÷ 1,21;

On the 3rd stage the value of ε_{eqv} is 1,21 ÷ 1,82.

The study of equivalent stress showed that when the length of the second channel matrix stress distribution is changed only at the junction of channels, while the deformation of rolls arising stress values are not changed. The average value of the equivalent stress is 140-170 MPa, a maximum of 200 MPa.

f) Models with a length of the second channel in the matrix L_2=20 mm.

Similarly to the previous model, the study of model with a length of second channel of matrix L_2 = 20 mm was noted that the value of the equivalent strain is reduced only to the 2nd and 3rd stages of the process.

On the 1st stage the value ε_{eqv} is 0 ÷ 0,617;

On the 2nd stage the value of ε_{eqv} is 0,617 ÷ 1,17;

On the 3rd stage the value of ε_{eqv} is 1,17 ÷ 1,76.

Similarly the model with a length of the channel matrix L_2 = 25 mm, using a step equal channel matrix with length of the second channel L_2 = 20 mm it was noted that the distribution of stress when the length of the second channel matrix changes only at the junction of channels. The average value of the equivalent stress is 130-160 MPa, 180 MPa maximum.

g) Models with the absolute reduction Δh=18 mm and Δh =20 mm.

The analysis of these models revealed that increasing the absolute reduction in the rolls increases value of equivalent strain sequentially at all three stages (fig. 4). In the model with Δh = 18 mm on 1st stage ε_{eqv} value is 0 ÷ 0,767; on 2nd stage ε_{eqv} value is 0,767 ÷ 1,53; on 3rd stage ε_{eqv} value is 1,53 ÷ 2,3. In the model with Δh = 20 mm on 1st stage ε_{eqv} value is 0 ÷ 0,843; on 2nd stage ε_{eqv} value is 0,843 ÷ 1,69; on 3rd stage ε_{eqv} value is 1,69 ÷ 2,53.

In the analysis of these models, it was found that the stress distribution with an increase of absolute reduction only changes in the deformation zones of rolls (Fig. 5), and the value of the equivalent stress increases. While at the junction channel matrix values of stress are not changed.

In a base model with Δh = 15 mm, the average value of the equivalent voltage power was 70-85 MPa at h = 18 mm it is 85-100 MPa; with Δh = 20 mm it reaches 95-115 MPa.

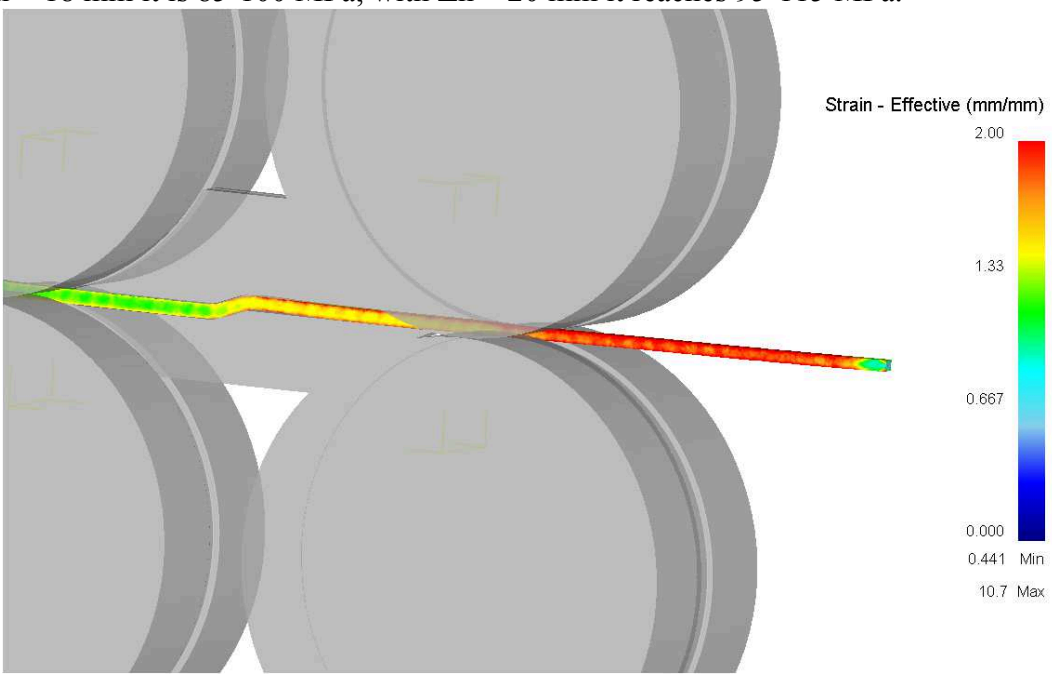

Figure 4 – Increasing of equivalent strain at all three stages

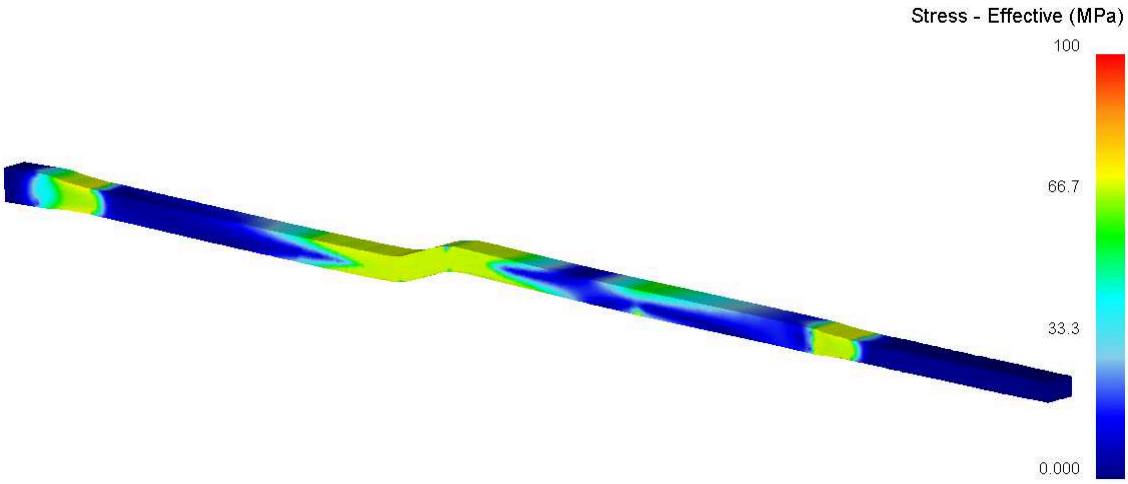

Figure 5 - Zones of deformation

h) Models with value of the friction coefficient in matrix μ_2=0,08 and μ_2=0,05.

Analysis of models with different values of the friction coefficient in the matrix showed that the decline in the value of this parameter contributes to a very slight decrease in the values of equivalent strain in the second and third stages of the process. At the first stage of the value of ε eq remains unchanged.

In the model with the value of the friction coefficient matrix μ_2 = 0,08 maximum equivalent strain ε_{eqv} decreased from 2.0 to 1.97, and in the model with the value of friction coefficient in matrix μ_2 = 0,05 - to 1.94.

Analysis of the stress state showed that the decrease in the coefficient of friction reduces the value of the equivalent stress in all three of the deformation zone. In the basic model for μ_2 = 0,1 average equivalent stress was 70-85 MPa, when μ_2 = 0,08 it is 67-70 MPa and when μ_2 = 0,05 it reaches 55-65 MPa.

i) Models with the value of billet temperature t=1200 °C and t=1000 °C

Analysis of models with different values of the billet temperature has shown that reduction of this parameter reduces the value of equivalent strain at all three stages, and an increase of temperature increases the intensity distribution of equivalent strain in the billet.

In the model with the value of the billet temperature t = 1200 °C on 1st stage ε_{eqv} value is 0 ÷ 0,703; on 2nd stage ε_{eqv} value is 0,703 ÷ 1,41; on 3rd stage ε_{eqv} value is 1,41 ÷ 2,11. In the model with the value of the preform temperature t = 1000 °C on 1st stage ε_{eqv} value is 0 ÷ 0,64; on 2nd stage ε_{eqv} value is 0,64 ÷ 1,28; on 3rd stage ε_{eqv} value is 1,28 ÷ 1,92.

Analysis of the stress state showed that the reduction of temperature increases the value of the equivalent stress in all three of the deformation zone, and an increase in temperature reduces the intensity distribution of the equivalent stress. In the basic model at t = 1100 °C average value of the equivalent stress is equal to 70-85 MPa, at t = 1200 °C it is equal to 67-70 MPa, at t = 1000 °C it reaches 85-95 MPa.

Conclusions

It was used to simulate the process of "rolling-pressing" with the use of grooved rolls and equal channel step matrix with varying basic geometric and technological factors which have a significant impact on the process. Analysis of the impact of various factors on the stress-strain state of the process has shown that factors such as the angle of the joint channel matrix, the coefficient of friction, temperature, length of the channel matrix have a significant impact on the stress-strain state in the whole volume of the workpiece in the implementation of the combined process of "rolling-pressing". And the only rational choice of mode of deformation for a given the profile and size of the workpiece, and consideration of all factors will make this complex process and end up getting a metal with sub-ultra-fine grain.

Keywords: PELE; tungsten fiber composite jacket; material parameters; penetrating performance; lateral damage effect.

Abstract: There are a series of disadvantages in tungsten alloy (TA), which is adopted as the jacket of PELE widely at present, such as inadequate obdurability, uncontrollable shape and amount of fragments, imperfect lateral damage effect, and so on. To solve the problem, tungsten fiber composite (TFC) is brought forward to produce PELE jacket. In order to verify its feasibility, numerical simulations are carried out on PELE impacting armor steel target with TFC jacket. The simulation results are compared with that of PELE with TA jacket and the reasons that the penetrating performance and lateral damage effect of PELE with TFC jacket being superior is discussed. After that, the function mechanism of PELE with TFC jacket is investigated through analyzing the influences of some factors on impacting behavior of PELE projectiles. These results can provide reliable theory and computational bases for future research.

Introduction

PELE (Penetrator with Enhanced Lateral Effect) is new ammunition which consists of a high-density jacket, closed at its rear end and filled with a low-density material. The exterior jacket has good penetration performance if fired against a steel plate, while the inner core has little penetration performance. If the projectile composed with above two materials hits a target the exterior jacket will penetrate successfully while the plastic filler will go forward tardily in the target. In the inner core an extremely high pressure will be generated leading to fragmentation of the outer structure once the projectile leaves the target [1,2]. The phenomenon is illustrated in Figure 1.

(a) At the beginning of penetration (b) Perforation of the target

Fig.1 Sketch map of functional principle of PELE

The exterior jacket, which answers for perforating targets and producing kill elements behind targets. The existing researches show there is an apparent difference in the penetration performance and lateral effect of PELE with distinct jackets [3,4]. For the high density and high strength, TA is adopted to armor-piercing projectiles widely at present, so to exterior jacket of PELE. Nevertheless, the inadequate obdurability of TA weakens the penetration performance of PELE with TA jacket in a certain extent [5], which results in the limited impacting ability of PELE. Moreover, TA jacket tends to fall to pieces naturally, which leads to uncontrollable shape and amount of fragments.

TFC are composed of tungsten fibers and an appropriate matrix. Due to the high density, high strength and big slenderness, tungsten fiber is the reinforcement and the main source of strength while the matrix glues all the fibers together in shape and transfers stresses between the reinforcing fibers. The existing researches show that the matrix sheds gradually during the penetrating process and

tungsten fibers answer for armor-piercing mainly. On account of the advantage of big slenderness, the penetration performance of TFC projectile overmatches that of TA projectile [6-8].

If TFC can be employed to produce jacket of PELE, thanks to the virtue of tungsten fibers, the penetration performance of PELE with TFC jacket would increase more. Furthermore, recurring to perfect matrix, in the inner core an extremely high pressure will be generated leading to disperse and fragmentation of the TFC jacket once the projectile leaves the target. The tungsten fibers and matrix fragments produced during above process would destroy objects behind the target and augment the destroy effect.

Paralleled with experiment, numerical simulation is a much more effective research means, which not only may obtain lots of datum that can't be derived from experiments to support theoretical analysis, but also can be carried out easily with different initialized boundaries, materials and structures and so on. To disclose the mechanism of the penetration performance and the lateral wrecking capability of PELE with TFC jacket, numerical simulations are carried out on the influences of some factors on terminal effect of PELE projectiles in this paper. Forenamed factors involve the diameter and volume fraction of tungsten fibers, and the sort of matrix. The study is put forward to increase the whole damage effect of PELE and further widen its employment scope.

Means of Numerical Simulation

In the paper, numerical simulation about the terminal effect of PELE with tungsten fiber composite jacket has been carried out, in which RHA plate is chosen as target and the impact velocity is 1500m/s.

The existing research indicates PELE will enhance its lateral effect availably when the slenderness ratio is in the range of 3~5 and inside tube radius ratio is between 0.5 and 0.7 [9]. Accordingly, the slenderness ratio is 4 and inside tube radius ratio is 0.6 in this paper. Idiographic dimensions of simulation models are as follows. The outer diameter and length of PELE is 30mm and 120mm apart, and that of inner core is 18mm and 110mm respectively. While the target is a 30mm-thickness quadrate plate, whose length and width is both 100mm. The PELE and target dimensions are quarter of the experiment model due to symmetry. The heat energy loss is ignored during the simulation.

The tungsten fibers and matrix are both simulated with PLASTIC_KINEMATIC material model combined with Von-Mises yield criteria, the inner core with VISCOELASTIC model, and the bottom of PELE and target are characterized with JOHNSON-COOK model and EOS_GRUNEISEN together. During the impacting process, the contact mode of ESTS is adopted between PELE and the target, while ASTS is introduced among constitutes of PELE [10].

Influence of Jacket Materials

The process of PELE with TFC jacket penetrating RHA with impact velocity of 1500m/s is simulated in this paper, in which PELE is composed of 40% tungsten fibers and 60% matrix, and the diameter of tungsten fibers is 1mm and the sort of matrix is ferro nickel alloy. Figure 2 shows the fragmentation and disperse of jacket behind target.

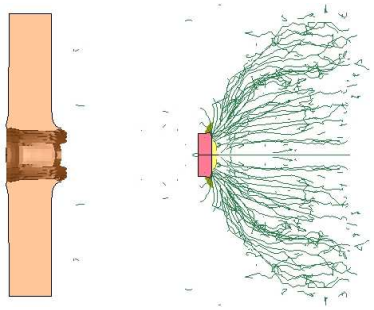

Fig.2 Lateral effect of PELE with TFC jacket

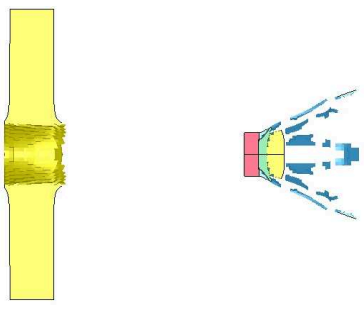

Fig.3 Lateral effect of PELE with TA jacket

To compare the lateral effects of PELE with different jackets, the process of PELE with TA jacket, adopting the same configuration and dimension as forenamed, penetrating RHA target with the same impact velocity is also simulated, and the corresponding result is shown in Figure 3.

Contrasted with Figure 3, some obvious characteristics are shown in Figure 2, such as the diameter of perforation being smaller, the debris being more plentiful and regular, and the lateral disperse angle of fragments being much bigger. Provided with the same impacting speed, the varieties of axial velocity and radial velocity of PELE with different jackets are shown in Figure 4 and Figure 5.

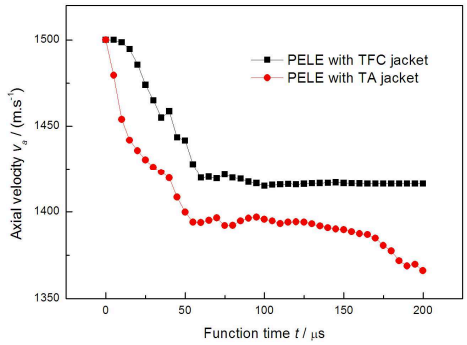

Fig.4 Axial velocity of PELE debris with different jackets

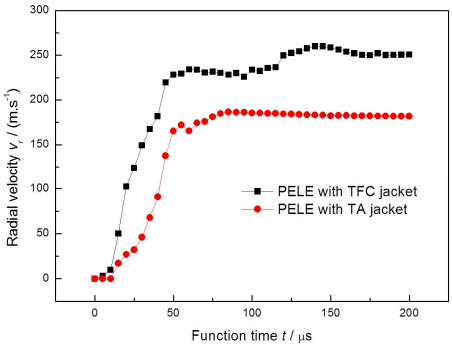

Fig.5 Radial velocity of PELE debris with different jackets

It can be seen from Figure 4 and 5 that the axial velocity and radial velocity of PELE with TFC jacket are both bigger than that of PELE with TA jacket. The underlying reasons for these phenomena lie in that under high strain rate loading there is a great compression of grains in axial orientation and the head of TA jacket will be formed as mushroom-head, shown as Figure 6. With the increasing of penetration depth, the mushroom-head grows up constantly, which widens the perforation further and weakens the penetration performance of PELE with TA jacket. But for PELE with TFC jacket, in the process of penetration the matrix ruptures abruptly as brittle material and tungsten fiber perforates mainly, shown as Figure 7. So the adiabatic shear failure is observed in the head of TFC jacket, which shows self-sharpening behavior and the penetration ability of jacket swells consequently. Because of the low tensile stress of the matrix, in the inner core an extremely high pressure will be generated leading to fragmentation of the outer jacket once PELE leaves the target and a mass of tungsten fibers debris with high radial velocity will be produced.

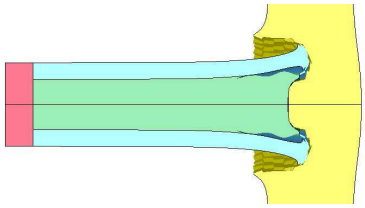

Fig.6 Mushroom-head of PELE with TA jacket

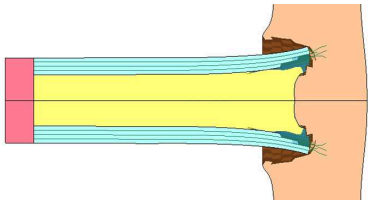

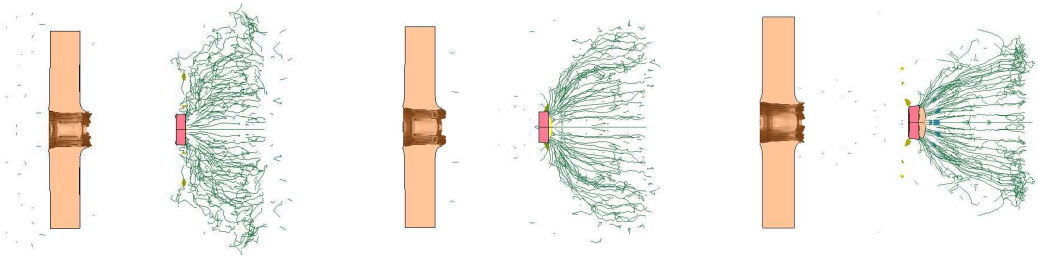

Fig.7 Self-sharpening of PELE with TFC jacket

Influence of Jacket Constitutes

Diameter of tungsten fibers

To investigate the influence of diameter of tungsten fibers on the terminal effect of PELE with TFC jacket, the process of PELE penetrating target perpendicularly with the same impact velocity is simulated, in which the target is 30mm RHA plate and the sort of composites matrix is ferro nickel always, while the diameter of tungsten fibers is 0.25mm, 0.5mm and 1mm respectively.

Figure 8 shows the lateral effect of PELE with TFC jacket adopting distinct diameter tungsten fibers, in which *d* denotes diameter of tungsten fibers. It can be seen that the diameter of tungsten fibers has much to do with the fragmentation and disperse of TFC jacket. That is, the thinner the tungsten fiber, the stronger the swelling during the penetrating process and the bigger the disperse angle of fragments behind target.

(a) d=0.25mm (b) d=0.5mm (c) d=1mm

Fig.8 Lateral effect of PELE with TFC jacket adopting distinct diameter tungsten fibers

During above simulation process, because of the same number and different diameters of tungsten fibers, PELE projectiles have distinct volume fractions of tungsten fibers and unlike density of jacket accordingly. The axial velocity and radial velocity of PELE debris with three different diameter tungsten fibers are shown in Figure 9 and Figure 10.

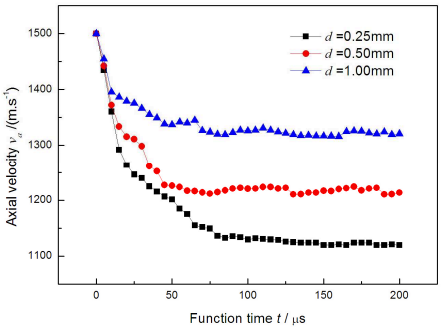

Fig.9 Axial velocity of PELE debris with different diameter tungsten fibers

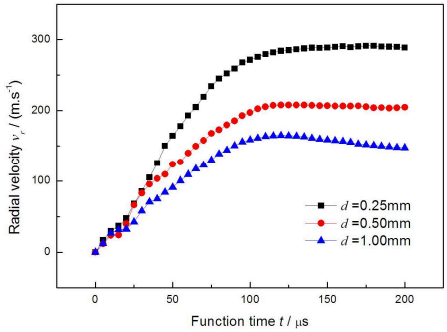

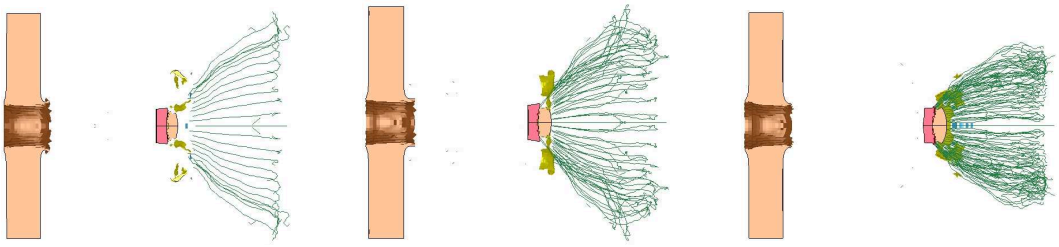

Fig.10 Radial velocity of PELE debris with different diameter tungsten fibers

It can be seen from Figure 9 that provided with same number tungsten fibers, the thicker the tungsten fiber, the bigger the residual axial velocity of PELE with TFC jacket behind target, which means PELE having more adequate penetration ability. The reason lies in that PELE jacket with thicker tungsten fibers has bigger density. While from Figure 10, it can be seen that the thicker the tungsten fiber, the smaller the radial velocity. That means PELE having more feeble penetration ability, which matches with the debris disperse in Figure 8 to the moment. For that matter, the imaginable causation rests with that, because of the more feeble penetration ability, it costs more time for PELE perforating target with thinner tungsten fibers, which leads to more axial kinetic energy turning to radial disperse energy in jacket owing to the swelling of inner core of PELE, thus tungsten fibers are inclined to disperse behind target more easily.

However, due to the limit of dimension, thicker tungsten fiber is not all better for PELE. To take account of the penetration ability and the lateral effect of jacket at the same time, the diameter of tungsten fiber should be in a reasonable range for PELE with a curtain dimension.

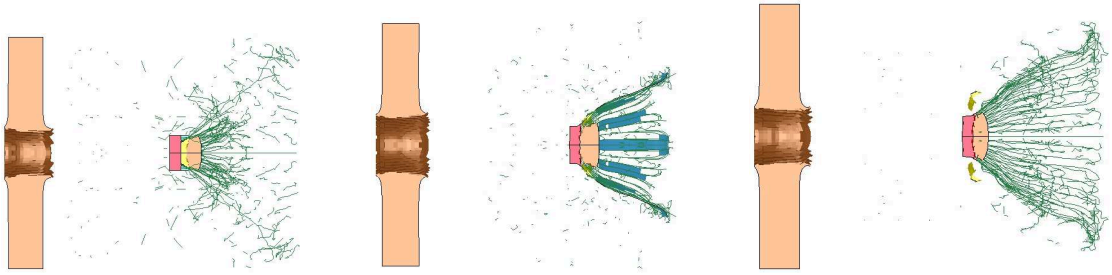
Volume fraction of tungsten fibers

To research the influence of volume fraction of tungsten fibers on the functional effect of PELE with TFC jacket, the process of PELE penetrating target is simulated, in which the sort of composites matrix is ferro nickel still and the diameter of tungsten fiber is uniform, while its volume fraction is 20%, 40% and 60% respectively. The lateral effect of PELE with TFC jacket adopting distinct volume fraction of tungsten fibers is shown in Figure 11, in which p denotes volume fraction of tungsten fibers.

(a) p=20% (b) p=40% (c) p=60%

Fig.11 Lateral effect of PELE with TFC jacket adopting distinct volume ratio of tungsten fibers

It can be learned from Figure 11 that the volume ratio of tungsten fibers also has much to do with the fragmentation and disperse of TFC jacket. That is to say, the bigger the volume ratio of tungsten fibers, the smaller the disperse angle of fragments behind target. Further more, study on the simulation results utilizing post processing software indicates that, the bigger the volume ratio of tungsten fibers, the bigger the residual axial velocity and the smaller the radial velocity. That means PELE having adequate penetration ability and feeble lateral disperse performance.



The potential reasons for these phenomena lie in that the irregularity of tungsten fibers in jacket because of its small volume percent, which leads to the difference of stress and strain environment among every tungsten fiber nearby consequentially. Herein, partial stress convergence happens, and rupture and failure come into being thus in some tungsten fibers. Then the strength of composites jacket weakens and its penetration performance reduces finally. With the augment of volume ratio of tungsten fibers, the main rupture manner alters from shearing to ripping gradually. Here, compress stress of jacket improves and the penetration ability swells.

Besides, simulations on PELE with TA jacket penetrating target with same configuration and dimension is also carried out. Comparison analysis shows that the strength of PELE with TA jacket is higher than that of PELE with TFC jacket as the volume ratio of tungsten fiber is on the small side, until it is bigger than a certain value. For the destroy performance of PELE is related to both axial velocity and radial speed, to give consideration to above two factors at the same time, the volume fraction of tungsten fibers should be in a sound range as to PELE.

Sort of bonding phase

Common fiber reinforced composites are composed of fibers and a matrix. Fibers are the reinforcement and the main source of strength while the matrix glues all the fibers together in shape and transfers stresses between the reinforcing fibers. Requirements for a matrix material usually include relatively low cost, easy achieve, and indiscerptible capability each other and so on. At present, aluminum, copper and ferro nickel alloy are the main matrixes used for tungsten fiber reinforced composites.

To study the influence of matrix on the terminal effect of PELE with TFC jacket, the process of PELE penetrating target is simulated, in which the diameter and volume ratio of tungsten fiber are uniform, while the matrix is aluminum, copper and ferro nickel alloy respectively. The lateral effects of PELE with TFC jacket adopting distinct matrixes are shown in Figure 12.

(a) Aluminum alloy (b) Copper alloy (c) Ferro nickel

Fig.12 Lateral effect of PELE with TFC jacket adopting distinct bonding phase

It can be learnt from Figure 12 that PELE jacket falls to pieces badly when its matrix is aluminum alloy and breaks up deficiently with copper alloy bonding phase, and only with ferro nickel alloy matrix can PELE produce perfect debris disperse. The primary functions of the matrix are to transfer stresses between the reinforcing fibers and damage duly to disperse the tungsten fibers. Compared with aluminum alloy bonding phase, ferro nickel has higher compress stress and transfers stresses between the tungsten fibers better, which keeps the uniformity of stress in composites jacket from easy failure of tungsten fibers and improves the penetration performance of PELE thus. On the other hand, contrasted with copper alloy matrix, ferro nickel has lower tensile stress, which would make the bonding phase brittle rupture easily and dismiss the tungsten fibers and then improve the lateral disperse performance.

Summary

It can be learned from numerical simulation results, compared with PELE with TA jacket, PELE with TFC jacket not only has self-sharpening during the penetrating process which improves its penetration ability, but also has the advantage of lower tensile stress and being prone to disperse which improves its lateral disperse performance. So it should be feasible in theory for PELE to produce jacket with tungsten fiber composites.

Farther researches show a series of results. With the same number of tungsten fibers, the thicker the tungsten fiber, the greater the penetration ability and the more difficult to disperse for PELE. The strength of PELE with TA jacket is higher than that of PELE with TFC jacket until the volume ratio of tungsten fiber is bigger than a certain value. Compared with other two matrixes, PELE with ferro nickel alloy matrix can produce perfect penetration performance and debris disperses almost. Above-mentioned analysis results may provide reliable theory and computational bases for future research of PELE with TFC jacket.

Keywords: oil-gas separator. separation efficiency. response surface methods(RSM). computational fluid dynamics

Abstract: Inside segregators, such as the air compressor, refrigerant and lubricant are mixed together. It is hoped that the lubricant could be reclaimed back to continue to work when it is expelled from the compressor**.** But designing of some kinds of air conditioning compressors has taken no notice of that, or it has lower separation efficiency. RSM (Response Surface Methods) is put forward to optimize the structure parameters so as to improve the separation efficiency. It is a collection of mathematical and statistical techniques, by which fewer experiments are needed to obtain the relationship between its parameters and their influences. Finally, by the use of computational fluid dynamics software, the optimum structure parameters are obtained, through which the better separation efficiency is available.

Introduction

Lubrication is very important to moving structures in machine comportants such as compressors, so that the good condition of machines is guaranteed to promote their life-span. The lubricant in gaseity condition is mixed with cold intermediary and together are expelled out of compressors. The leakage of lubricant would put structures at a disadvantage so a separation cavity is designed at its exit which would disjoin lubricant and intermediary to make lubricant reuse as good as possible. The mechanism of the separation is cyclone by which the big mass would be swung to the wall to go back to the compressor because of their different desity[1].

Separation Simulation of lubricant with cold intermediary is accomplished with the computational fluid dynamics software to obtain some parameters affecting the separation efficiency. In order to get the best results, the parameter optimization is needed with the help of Response Surface Methods (RSM) to ensure the optimum structure parameters with as fewer experiments taking as possible.

The Basic Principle of RSM

Although optimum values may be received through some common optimization means, intuitionistic graphs could not be observed and it is difficult to distinguish the optimum region and points. So RSM emerges as the times require. It is a kind of optimization method, which defines the system response (for example, the extraction rate in extraction chemistry) as the function of one or many factors (e.g., the concentration of extraction agent, its acidity, etc.). RSM reveals this kind of relationship using graphics techniques to let designers choose optimum conditions by instinct observation. RSM may perceive and confirm the response influences to make certain their feedback, and the respond may be the biggest or the smallest value.

RSM is a kind of sequence methods. Generally, when a point is located far from the optimum point, the first-order model is suitable for a little bending existed in the system. Therefore, the experiment is aimed at leading triers to go forward along the route to find the optimum fastly and effectively. Once the optimum region is found, the more refined model (e.g., the second-order one) may be utiliyzed to fix the optimum point. The analysis of RSM would be imagined as to climb a

moutain, with its top representing a maximum point of the reponse. If the true optimum is the smallest point of the reponse, the aforementioned analysis would be thought as falling down into a valley[2].

The conventional optimization may be put forward as[3,4]

$$\left.\begin{array}{l} \text{Seeking} \quad x \in E \\ \text{So that} \quad y_0(x) \to \min \\ s.t \quad y_j(x) \le 0; \quad \underline{x_i} \le x_i \le \overline{x_i} \\ (i = 1, \cdots, n; j = 1, \cdots n_c) \end{array}\right\}. \tag{1}$$

Where n, n_c stand for the number of variables and restricted functions respectively.

RSM is applied to express the objective funtion $y_0(x)$ or restricted funtion $y_i(x)$ as the function of x_i explicitly, which are difficult to do so with other means so as to solve Eq.1 using the optimization settler. For example, the linear equation is listed below

$$\eta(x) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \cdots + \beta_n x_n . \tag{2}$$

Then a non-linear restricted optimization model is attained finally

$$\left.\begin{array}{l} y_0(x) = x^T H x + f^T x \to \min \\ s.t \quad \sum_{i=1}^{n} \sum_{r=1}^{n} \beta_{jir} x_i x_r \le b_j \\ \underline{x_i} \le x_i \le \overline{x_i} (i = 1, \cdots, n) \end{array}\right\}. \tag{3}$$

Where y is the response function, x_i stands for a $(k \times 1)$ vector of predicting variables, b represents the coefficient vector, and β_i the linear multi-variables regression analysis estimation (unknown coefficients), n the number of variables; H is a $(k \times k)$ symmetric matrix whose main diagonal elements are the pure quadratic coefficients and whose off-diagonal elements are one-half the mixed quadratic coefficients; f is a $(k \times 1)$ vector of the first –order regression coefficients.

The convergence rule is

$$\Delta y_0^k = \left| (y_0^{k+1} - y_0^k) \Big/ y_0^{k+1} \right| \le \varepsilon . \tag{4}$$

Where y_0^k and y_0^{k+1} are objective function values of the former and later iterating.

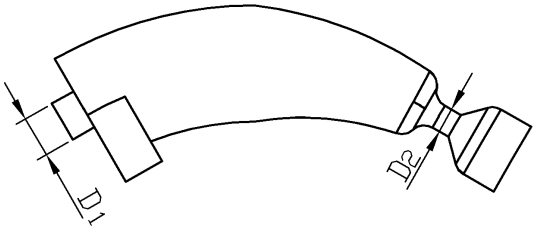
Analysis and Optimization of Computational Fluid Dynamics Software

The Computational Fluid Model and Optimization of Structure Parameters

The model of the separation cavity is showed in Fig.1, where D_1 stands for its exit diameter and D_2 its lubrication mouth diameter. Calculation of phase field is performed with the SIMPLE arithmetic and oil dripping is tracted by the dislete phase model. With the initial location, speed, dimensions and temperature predefined according to its physical characteristics, its trajectory is initialized and the amount of heat transfering/mass is performed. When granule moves through fluid, their trajectory and the amount of heat and mass tranfering may be calculated based on various balancing forces, as well as the amount of convection and radialization of heat and mass. The RNGk-ε model is adopted as the onflow model. The oil dripping diameter is 4μm and its entrance speed is 19m/s which is defined as the escaping borderline, altogether with the outflow. The wall-face is defined as “trap” form, by which the oil dripping would be caught when it reaches it[5,6]. The oil dripping moving trajectory is simulated and then showed in Fig. 2.

The structure parameters taken into account in simulation are cold intermediary exit diameter D_1 and lubricant going-back diameter D_2. The optimization objective is the maximum value of separation efficiency μ.

The range of D_1 and D_2 are defined as follows
$2mm \leq D_1 \leq 6mm$, $4mm \leq D_2 \leq 10mm$



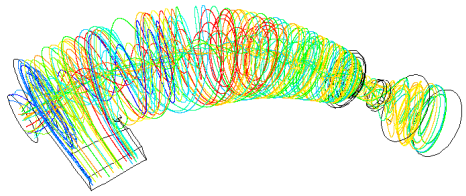


Fig.1 Structure of the separation cavity

Fig.2 Oil dripping moving trajectory during separation

Response Surface Optimization

According to CCD(Central Composite Design) test designing principle, separation efficiency optimization is carried out with the help of Response Surface Analysis. The test diagram and results are listed in Table 1. 13 tests are included, where various values of D_1 and D_2 are tried and a fitting regression(Eq.5) is reached. On the basis of the fitting function, a response surface is made out.

$$\mu=0.22399+0.10247\,D_1+0.083393D_2-1\times10^{-3}D_1D_2-0.011759\times D_1{}^2-6.08750\times10^{-3}D_2{}^2 \quad (5)$$

TABLE 1 TEST DIAGRAM DESIGNING AND DATA PROCESSING

No.	D_1[mm] (cold intermediary exit diameter)	D_2[mm] (lubricant mouth diameter)	**μ (separation efficiency)**
1	4	7	0.70
2	4	7	0.71
3	4	2.76	0.64
4	6.83	7	0.62
5	4	7	0.71
6	6	4	0.61
7	2	10	0.59
8	2	4	0.59
9	6	10	0.58
10	4	7	0.72
11	4	7	0.67
12	1.17	7	0.61
13	4	11.24	0.56

Influence of both parameters D_1 and D_2 on the separation efficiency is showed in Fig.3. When D_1 remains unchanged, the separation efficiency μ increases along with D_2 firstly, then decreases after it arrives at its maximum value. In the samilar way, when D_2 keeping steady, first of all, μ enlarges with D_1, then decreases after it attains to its crest. When D_1=4mm, D_2=7mm, a maximum μ is got, that is, μ_{max}=72%.

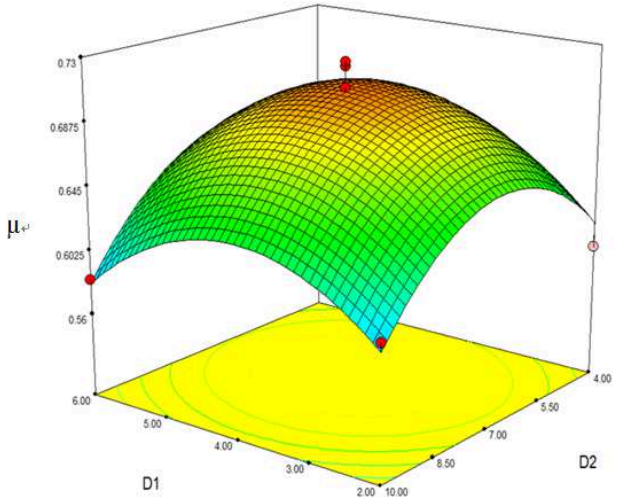

Fig.3 Response surface of both parameters D_1 and D_2 on separation efficiency

Conclusion

Based on the above optimization test, a maximum separation efficiency is achieved, μ_{max}=72%. Then based on the same parameters, the value of μ=72.5% is acquired validated by the hydrodynamics calculation, which proves the reliability of the above method. Based on RSM, the objective function or restriction may be approximately expressed with designing variables so clearly, that complex optimization could be turned into linear or non-linear restricted one and iterated with the advanced settler. Through the set-up of hydrodynamics simulation testing plan and reasonably arranging parameters, the optimum value would be got finally. This method would provide valuable reference to separation cavity structure designing.

Keywords: non-asbestos; hybrid fiber; manufacturing

Abstract: Under the fiber hybrid effect, the merits of organic and inorganic fibers were integrated. The appropriate organic and inorganic fibers were chosen to prepare the non-asbestos gasket which meets the usage requirements and has a good cost performance. The ratio of basic craft and materials for industrial production were obtained. Results indicate the new non-asbestos gasket which is made by non-asbestos fibers and enhanced rubber adhesive has reached the performance of similar international products and has formed our unique non-asbestos sealing materials.

Introduction

Preface

Sealing material is widely used in petroleum, chemical industry, machinery, automobile, etc. Because of its high tensile strength, large surface area, good adsorption performance, asbestos fibers are widely used to make the main body of soft sealing packing and gasket materials. However, long-term inhalation of asbestos dust can cause asbestos AD cool-headed disease, asbestosis and cancer. The asbestos fiber causes serious damage to human body health[1]. The developed countries have put forward strictly limits on the use of asbestos[2]. In our country such as asbestosis an occupational disease prevention and control of asbestos are paid more and more attention. Foreign non-asbestos sealing materials research and development have made great progress. Entered the practical stage, the domestic research and developed quickly. At present, fiber including Kevlar fiber, Aramid fibers, cellulose fiber and various inorganic fibers are commonly used. But in known fiber material, there is no a kind of fiber which can completely replace the asbestos fiber, which limits the non-asbestos sealing composites reinforced by a single fiber of popularization and application. Therefore, the author uses fiber hybrid effect, the synthesis of organic and inorganic fiber one's respective advantage. Choosing the right variety of inorganic and organic fiber has a good cost performance of non-asbestos sealing gasket and the development of non-asbestos gasket is analyzed and compared to the level of similar foreign products.

Test Materials And Test Methods

Test Materials

In the early stage of the study[3 ~6], based on choose raw materials as follows: cellulose fiber and mineral fiber, aramid pulp, pulp fiber, aromatic polyamide fiber, rubber adhesive, silica, mica, calcium carbonate, talcum powder, kaolin, diatomite, wollastonite, surface active agent, coupling agent, paper alum, etc.

Test Method

Experimental methods: determining the copy [7] as the basic production process, according to the performance requirements for materials design product formula and production process, for determining the copy without asbestos sealing gasket pilot, have achieved using requirements and a good cost performance of non-asbestos sealing gasket, basic scientific research, and analysis and comparison with similar foreign products.

Test the main equipment: grinding machine, plate mill, taking into a copy machine, vacuum device and so on.

Testing equipment: WE - 30 hydraulic universal material testing machine, CSS44020 tensile tester, TM3000 scanning electron microscope, optical microscope.

The Results Of The Experiment And Analysis

Single Fiber And Hybrid Fiber Structure Analysis

Figure 1 and figure 2 are respectively separate mineral cotton fiber and mineral fiber, cellulose fiber and aramid pulp fibers taking the SEM photo of paper copy. From figure 1, you can see, most of the latex can absorb the fiber, but there are some fibers which failed to absorb on fiber latex. This will lead to the end product is not uniform, and has larger entanglement between fiber, poor dispersibility; Figure 2, the hybrid fiber dispersion is separately using mineral cotton fiber, which has better effect with glue and a winding. Therefore, the strengthen effect is good, which can be lost in rubber matrix effect after the material having some residual strength. Therefore, it has a better performance is with mineral cotton fiber mixed with a certain amount of aramid pulp, cellulose fiber than replace asbestos fiber preparation with single fiber latex copy without asbestos gasket.

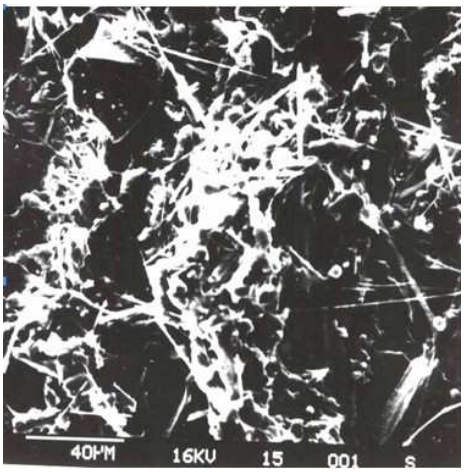

Figure 1 SEM Figure of Mineral Cotton Fiber

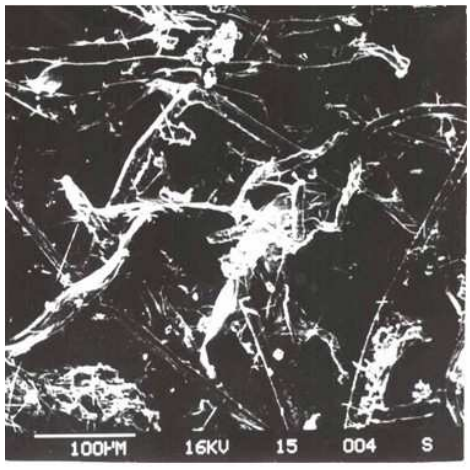

Figure 2 SEM Figure of Hybrid Fiber

Latex - Packing - Fiber Content Of Optimization

Improving the content of latex can make material more elastic, and provide a better sealing. But it lowers the stability under high temperature stress. If using two or more different average particle diameter of packing, the combination of particle will closely unifies together. This will have less space for rubber. Early non-asbestos gasket materials mainly use aramid pulp as reinforcing fiber. This is because the aramid pulp has the obvious advantages such as high strength, large specific surface area. But the cost is high. So, to sum up, the lower content of latex formula mixed aramid pulp, mineral cotton fiber (long fiber and short fiber) and cellulose fiber, and reducing the amount of aramid pulp, chooses different granularity of packing at the same time, to reduce production costs and make products with good comprehensive performance.

The Use Of Other Additives And Processing Aids

(1) To join the right amount of surfactant, improve the composition of surface charge, make the fiber surface with a negative charge, outer rubber latex particles with positive charge, the polymer particles attracted by fiber and polymer particle agglomeration effect and deposited on the fiber surface.

(2) To join the right amount of coupling agent, enhance the cohesive force between packing and latex substance, in the multiphase system formed in the good interface, the material has excellent overall performance.

Performance Analysis Under Different Formula

Picking two formula optimization shows in table 1: the performance of the product shows in table 2 (and compared with foreign interface products).

TABLE 1 SELECTED FORMULA

Composition	Quality percentage (wt ％)	
	A	B
Kaolin	32	33
White carbon black	2	3
Talcum powder	9	11
Mica	3	3
Rubber adhesive	16	18
Mineral cotton fiber	28	23
Cellulose	7	6
Aramid fibers	3	3

Known from table 2: using latex copy process and using without contain asbestos composition of inorganic fibers mixed with organic fiber reinforced rubber adhesive preparation of a new type of sealing gasket and similar foreign products than its tensile strength, compression spring rate, sealing and other major technical indicators have reached the level of similar foreign products, formed with characteristic of our country which has no asbestos sealing plate.

Conclusions

(1) The hybrid aramid pulp, mineral cotton fiber (long fiber and short fiber) and cellulose fiber, and reducing the amount of aramid pulp, and choosing different packing sizes, can reduce the production cost and make products with good comprehensive performance.

(2) To join the right amount of surface active agent, coupling agent and paper making alum can play the role of material to improve overall performance.

(3) Preparing a new type of sealing gasket has been basically achieved the performance of the same products abroad. However, comparing with the similar foreign products remain with poor product density will be improved in future research.

Keywords: Submersible screw pump; Nitrile rubber; Acrylonitrile content; Swelling properties; Mechanical properties.

Abstract. By the research of swelling and mechanical properties of nitrile rubber with different acrylonitrile contents in cyclohexane medium, the influences of physical and mechanical properties with diffrent acrylonitrile contents is analyzed. The results indicated that: the quality of all the nitrile-butadiene rubbers with different acrylonitrile contents is increasing with the increase of soaking time. It increases rapidly in the first 24 hours then gently. With the increase of the acrylonitrile content, the increasing proportions of swilling quality is reduceing. But N40 cyclohexane performance is better relatively. After drying the three kinds of rubber in 110 degrees Celsius, all the qualities is lower than the original value. It means that in swelling process, the material in rubber is pulled out and the distance between the rubber molecules decreases. After swilling the three kinds of rubber, their hardness decreases and the decline proportion is reducing by the increase of acrylonitrile content. With different acrylonitrile contents and swilling times the nitrile rubber shows different mechanical properties. After soaking three kinds of rubber their tensile strengthes are on the decline by swilling time and their rates of permanent deformation are on the rise. It shows that as the swelling time extended, the mechanical properties descends and the corresponding indicators after soaked and dried is lower than the quantitative values after soaked. The study has a certain reference of design of ESPCP stator under certain operating conditions.

Introduction

As a new oil extraction and lifting equipment, the submersible screw pump has a great development and application with its unique advantage [1]. As an important component of screw pump, the material of stators is nitrile rubber mostly and chose different formula according to the different conditions [2,3].Screw pump is often used in high temperature ,high pressure, corrosive medium and periodic extrusion etc conditions, so the stator rubber inevitably appears swelling phenomenon. That makes the stator rubber machinery performance degradation and influence the efficiency of screw pump oil production. So the elastic stator material of screw pump must have a good swelling resistance, corrosion resistance, abrasion resistance and other properties[4—8]. The results indicated that: if the acrylonitrile contention in NBR is changed the performance of the rubber will be change too[9—12].Three kinds of NBR with different content of acrylonitrile were selected for crude oil swelling. As the complicated composition of crude oil, it is difficult to analysis the phenomenon of swelling. So cyclohexane is selected as the medium of swelling which is a representative cycloparaffin in crude oil. By researching the influence of different acrylonitrile content and soaking time to the quality of nitrile rubber, hardness, the volume and mechanical properties ,comparative analysing and revealing the swelling mechanism, it will provide a basis for the research and development of new formula and product a reasonable evaluation system of screw pump rubber.

Experimental

Materials

The three kinds of NBR in this experiment adopt the acrylonitrile content 18%, 26%, 41%and the base formula of NBR contains: zinc oxide, stearic acid, protective agent, carbon black, plasticizer, vulcanizing agent, promoter. For the purposes of comparison, the three kinds of rubber formula try to only change the content of carbon black and the other components remain the same, so as to achieve the shoreA hardness of three rubbers is 70 after vulcanization, and other additives should be optimized according to the general oil resistant seal matching principle of NBR as far as possible. With the opening-style rubber-mixing machine and plant vulcanizing press produced by Qingdao Yadong Machinery Group Company Limited, the temperature, pressure, the time required for sulfide can be measured by the Rheometer which produced in the GOTECH testing machines incorporate .

Experimental Techniques

Firstly, specimens of each NBR is prepared according to the standard GB/T1690-2006 (vulcanized rubber or Liquid-resistant thermoplastic rubber test methods), swelling the three kinds of NBR in cyclohexane with normal temperature and pressure. The size of rubber sample is 40mm×20mm×5mm, and the soak time is 24h, 48h, 72h, 120h and168h for respectively. With 0.1 mg precision weighing electronic balance, weighing the quality of the samples before and after swelling, and using LX - A rubber hardness tester measuring the hardness of rubber sample. Taking some soaking specimens in drying oven, drying experiment is carried out in 100 ℃and9 h.

Secondly, according to the standard GB/T528-1998(vulcanized rubber or thermoplastic rubber determination of tensile stress strain properties), test the three rubber specimens using a tensile testing machine for mechanical performance before and after swelling and drying, cutting the samples as dumbbell shaped II type, the tensile speed is 500mm/min range of 20 mm. All the measured experimental data are the average of three times that resulted from experiments.

The percentage mass change (△m) after soaking and drying of samples are calculated by the following formulas. Three specimens were used and the average value was calculated.

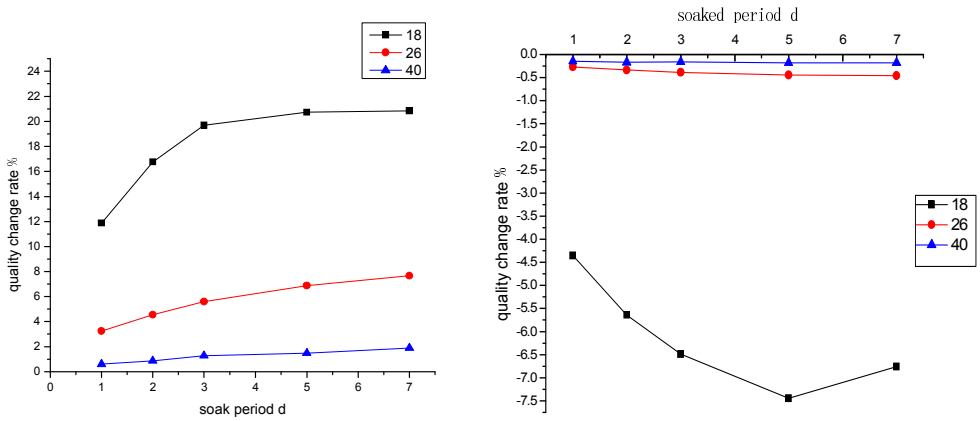
$$\Delta m = \frac{m_2 - m_1}{m_1} \times 100\% \quad (1)$$

Where, m_1 and m_2 are the weight of the specimen in air before and after immersion respectively, g.

Express the permanent deformation rate in R, it was determined as:

$$R = \frac{L_t - L_b}{L_b} \times 100\% \quad (2)$$

Where, Lt is the scale distance after sample fractured and placed up 3 min later,mm; Lb is the scale distance while the sample fractured,mm.



Results and Discussion

Mass Change Rate

In figure 1 (a),it is the quality change curve with immersion time for the different content of acrylonitrile rubber specimen swelling in cyclohexane reagent. From that, over time, the quality of rubber samples are gradually increased, the increase proportion of N18 is the largest, the

quality increase percentage is 20.84% after swelling seven days .In the second place the largest swelling percentage is 7.66% by N26, the N40 has the least quality increase by 1.9%. The swelling quantity of three kinds of NBR increased most rapidly in first 24h, and then the increase becomes gentle gradually, after 72 hours swelling changes are less. The cause of above phenomenon is the imparity of solubility parameters (SP). Due to swelling phenomenon is greatly influenced by SP, the closer between rubber and solvent SP, the greater with rubber swelling. The cyclohexane SP value is 8.3 and the SP of N18, N26, N40 are 8.7～8.8, 9.4～9.9 and10.3～10.5. Because cyclohexane and N18 SP values are most close, the quality of N18 swelling increment is the largest, followed by N26, minimum incremental quality is N40.

Figure 1 (b) is the quality change curve with immersion time for three kinds of different acrylonitrile content NBR specimen that soaked in cyclohexane reagent and dryed. It can be seen from the diagram that the three kinds of rubber is less than the original quality after drying, and the amount of reduced is increase along with the increasing of acrylonitrile content. The reduce proportion of N18 is the largest, the quality reduce percentage is 7.44% after dried .In the second place is1.11% by N26, the N40 has the least quality reduce by 0.18%. N18, N26 shows the quality decrease is increased with the extension swelling time but the quality decrease of N40 is approximate to constant over time .The quality reduced after drying that indicates cyclohexane has entered into rubber mesh structure, but at the same time some additives small molecules in rubber is separated out and spread into the reagent.With the increase of acrylonitrile content, the distance between the molecules is reduced, the intermolecular force increases, which makes a difficult plasticizer migration from the NBR. And after soaking the solvent color changed from colorless to yellow, with the increase of the acrylonitrile content, yellow solvent becomes shallow gradually, shows that the amount of precipitation gradually reduced.

（a）swelled NBR （b）dried NBR

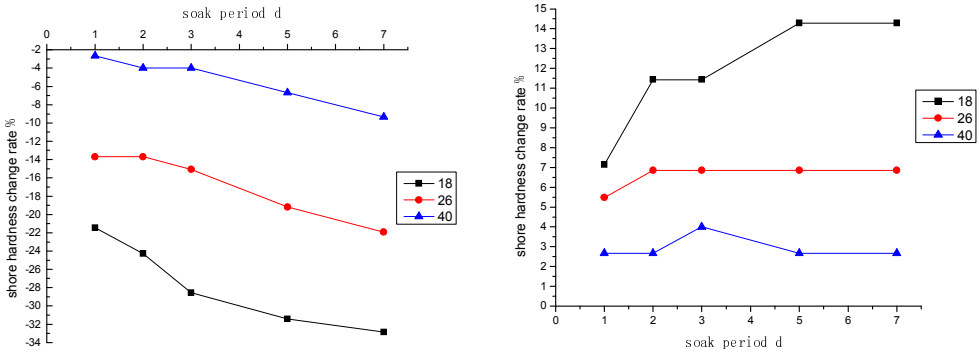


Fig.1 The Quality Change Rate Of Swelled And Dried Nbr In Different Soak Periods

Hardness Change Rate

Figure 2 shows the rubber shaw hardness percentage change curve after swelling and drying in different soaking time. Figure 2 (a) showed that three kinds of rubber hardness decreases obviously after swelling in cyclohexane medium, and there is a approximate linear relationship between the reduce hardness and soak time. In the contact of rubber and cyclohexane the intermolecular force between cyclohexane and rubber molecules is greater than the rubber

molecules internal forces.So cyclohexane molecules can spread into the rubber mesh structure and damage the junction, that results a rubber hardness reduction. With the increase of the acrylonitrile content the rubber hardness decline, in turn, reducesd. The hardness of N18 and N26 decreased most rapidly in first 24h, and then the increase gradually flattened out over time; the change of N40 is approximate uniform decline.With the increase of the acrylonitrile content,the nitrile groupings(-CN) in NBR increases and molecular inter-atomic forces increases. In the process of swelling, the damage of cyclohexane to rubber junction reduced and the proportion of hardness decreased less.

In figure 2 (b), all the rubber hardness increased after drying, with the extension of swelling time, the increasing hardness rate of N18 increased. N26 and N40 hardness changed approximatively as a straight line. Rubber hardness increase after drying, because the plasticizer is pumped out from NBR. As time changes, the plasticizer proportion of N18 which pumped out continuously increased. And the plasticizer proportion of N26 and N40has a poorer correlation to swelling time . With the increase of the acrylonitrile content, the force between plasticizer and rubber matrix get stronger and difficult to be pulled out.

（a） swelled NBR （b）dried NBR

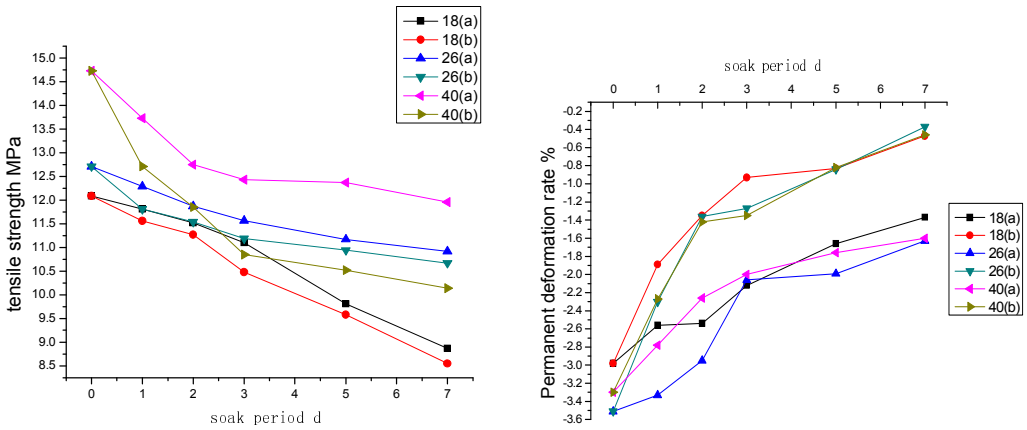

Fig.2 The Shore Hardness Change Rate Of Swelled And Dried Nbr In Different Soak Periods

Mechanical Properties

Tensile properties is one of the most important measure to the physical properties of rubber. Figure 3 shows the samples change rate curve of tensile strength, permanent deformation in different swelling and drying time. From figure 3 (a) it can be seen clearly that with the extension of soaking time the tensile strength of three kinds of rubber after cyclohexane soaked is on the decline by the mechanics performance reduction. According to the theory about the number of net chain that have been put forward by Flory[13], the reason is that the number of effective mesh chain in NBR declined after swelling. After cyclohexane spread into rubber, the rubber net structure has changed; physical junction fractured; net structure appeared cracks and pores, that makes mechanical performance of NBR felled sharply.

To three kinds of rubber the tensile strength is on the decline with the extension of swelling time. But at corresponding time points, with the increase of the acrylonitrile content, the tensile strength increased. With the increase of the acrylonitrile content,the nitrile groupings(-CN) in NBR increases and molecular inter-atomic forces increases it makes the tensile strength increase. After drying three kinds of rubber tensile strength are all lower than the swelling value. On the first two time points the tensile strength increases with the increase of acrylonitrile content; but on the other time points,

N26 has the largest tensile strength, N18 is minimum and N40 is in the middle but has a smaller gap with N26 . It is mainly because after swelled and dried, rubber auxiliaries were pulled out, hardness increased, elasticity and tensile strength decreased. N26, N40 due to acrylonitrile content increases, the cohesive force between the molecules increased; the extract increase less after 48 hours, so the both tensile strength are similar after two days.

（a） （b）

Fig.3 The Mechanical Properties Change Of Swelled And Dried Nbr In Different Soak Periods

In Figure 3 (b) it shows permanent deformation rate of three kinds rubber presents a rising trend with the extension of swelling time, which shows the rubber rebound ability and the ability to resist deformation is poor. There are many factors can influence the rate of the permanent deformation such as rubber net structure between the molecules; molecular force; displacement between the molecules and so on. The springback ability of the original NBR, N18 is the worst, N40 is better and N26 is the best.

With the increase of the acrylonitrile content, nitrile groups (-CN) increases, the molecular spacing decreases, and conducives to the crosslinking reaction.A high degree of crosslinking can reduce the displacement and stress relaxation of rubber molecules .It can also keep a high the deformation recovery capability and a smaller permanent deformation rate.But N40 has a exorbitant acrylonitrile content and polarity is too large. The movement of macromolecular chain is limited.It influenced the crosslinking reaction of free radicals, and the crosslinking density decreased. So the permanent deformation rate will be lower than N26 on the absolute value. With the increase of soaking time, N18 also has a poor resilience, the permanent deformation of N26 and N40 are close to each other. This phenomenon is attributed to the cyclohexane that diffused into the grid structure of NBR ; destroyed the rubber crosslinking structure ; declined the crosslink density of N26.But the macromolecular motion constrained problem of the N40 has been solved. So that the rate of permanent deformation is constantly close to N26 and N40.

After soaked and dried the NBR rates of permanent deformation are on the rise by swilling time. Initially N18 has a poor resilience than other NBR and the permanent deformation rate of N26 is close to N40. On the fifth day, all the NBR specimen after soaked and dried have poor resiliences ,the rates of permanent deformation is approach to each other. The change rate of swelling increases rapidly in the first day then gently, until balance is reached. The grid structure of NBR has the same variation tendency, So in the Figure 4 (b)there has three curves of the dried NBR.

Summary

In this paper we have investigated the Swelling phenomenon of three NBR with different acrylonitrile contents in cyclohexane medium, the influences of physical and mechanical properties with diffrent acrylonitrile contents is analyzed. The results show that the mass, hardness, tensile strength, permanent deformation rate of three kinds NBR are affected obviously by cyclohexane. At the same time, performance differences of the three kinds NBR are related closely to the containing of the acrylonitrile content.

Effect of Reserved Texture on Mechanical Properties of Cold Drawn Pearlitic Steel Wire

Lichu Zhou, Yufei Zhao, Feng Fang*

School of Materials Science and Engineering, Southeast University, Nanjing, 211189, China

*Fangfeng@seu.edu.cn

Keywords：pearlitic wire, texture, cold drawn

Abstract: In this paper, pearlitic steel wire with/without reserved texture were investigated with the help of mechanical test system, scanning electron microscope (SEM) and XRD. Experimental result shows that: Tensile strength of two wire are almost same. After cold drawn tensile strength of wire with reserved texture are higher than tensile strength of the without one. Before cold drawn, two wires have same microstructure of isometric pearlite and after drawing the wire with reserved texture has less shear deformed pearlitic colony. Intensity of <110> fiber texture in the wire with reserved texture are stronger than the without one at all strains. The stronger <110> texture mean the orientation of α-ferrite lamella were more closely and improve working hardening rate of pearlitic wire

Introduction

High strength steel wire was widely used in many fields, such as wire rope, tire cord, springs and suspension bridge cable[1]. Relative research[2-5] on deformation pearlitic wire focused on controlling microstructure to improve the tensile strength of steel wire have achieved a great deal of success that it have reported the tensile strength of cold drawn pearlitic steel wire have achieved 6.3GPa. Evolution of texture during drawing was also widely investigated[6,7] but there were no research on how the texture affect mechanical properties of steel wire. Recent studies[8,9], texture of α-ferrite in cold drawn steel should be reserved after austenite heat treatment. How is the effect of reserved texture on the cold drawing process should be focus on.

In this paper, deformed pearlitic steel wires with/without reserved texture was investigated. Effect of reserved texture on mechanical properties of cold drawn wire was discussed.

Experimental Procedure

Pearlitic steel wires used were produced by Sha-steel Group Company, PR China. The chemical composition of the wires were shown in Table1.

TABLE 1 COMPOSITION ANALYSIS OF EXPERIMENTAL STEELS (WT%)

C	Si	Mn	Cr	V	S	Fe
0.83	0.3	0.71	0.19	0.07	0.003	Bal.

After pickling and phosphating[10], hot-rolled wire rods (12mm and 5.5mm diameter) were successively drawn to a diameter of 5.1 mm with a total reduction of 82% and 14% (ie., ε=1.7 and 0.15).

Heat treatment of deformed wires were carried out in salt bath of 950℃ for 5 min, Wires were put into salt bath of 550℃ for 5 min at once. After in salt bath wires were cold in air to room temperature. After treatment, the wire drawn from 12mm have reserved texture and wire from 5.5mm have no reserved texture.

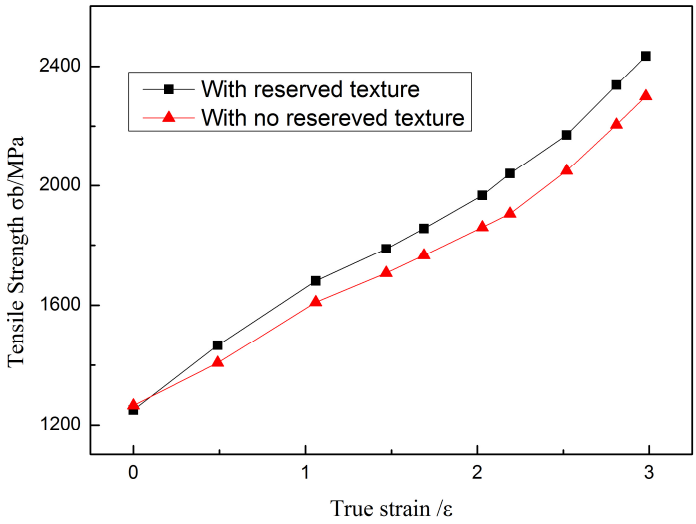
Tensile strength of this wires were tested by using a universal testing machine. This test were operating at a constant speed of 2 mm/min. Evolution of microstructure of cold drawn wires was examined using a FEI Siron-400 scanning electron microscope (SEM). Texture tested were used D-Max 2000 to test three pole figures calculated to integral pole figure. Using integral pole figure to calculate the intensity of <110> fiber texture.

Results and Discussion

Mechanical Properties

The tensile strength of wires as a function of true strain was presented in figure 1.

Tensile strength of wires increase with the increase of true strain from 0 to 3. Before drawing, this two steel wires with/without different reserved texture have almost same tensile strength. After cold drawing , tensile strength of steel wire with reserved texture are higher than the without one. Reserved texture improve working hardening rate of pearlitic wire.



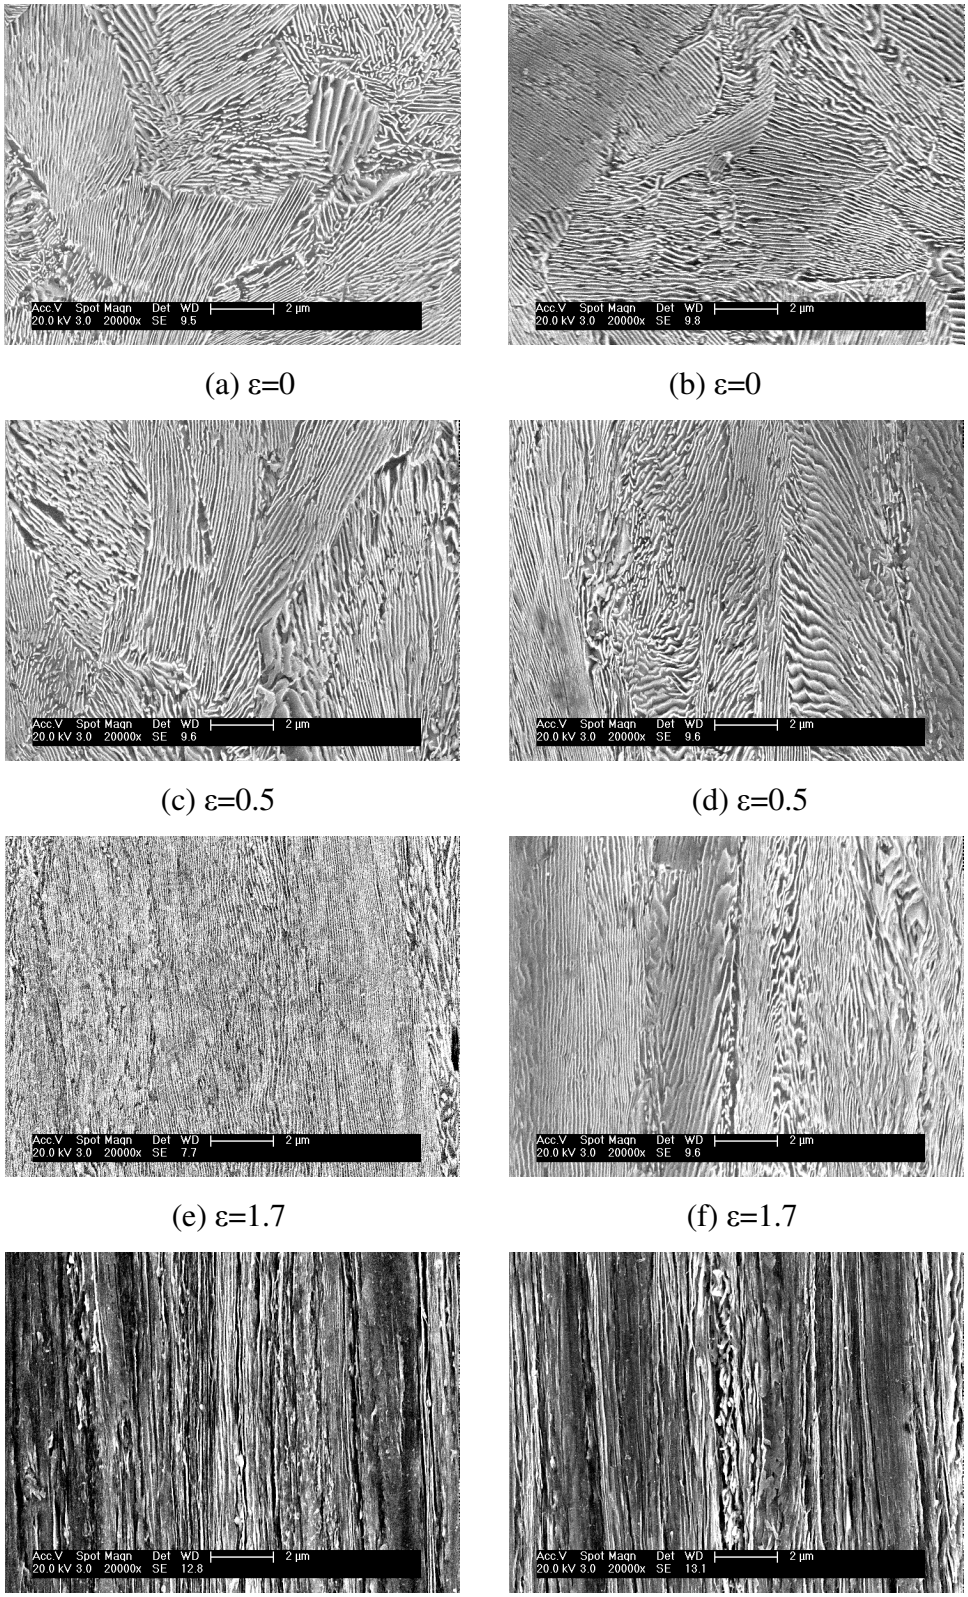


Fig.1. Relationship Between Tensile Strength and True Strain of Two Wires

Microstructure Evolution

Wires were observed from the longitudinal section as figure 2. Figure 2a,2b show before drawing, both of the two pearlitic wires' microstructure are same isometric pearlite. Lamellae of ferrite and cementite is complete and parallel to each other in one colony.

After drawing pearlitic lamella of wires thinned and rotated to be parallel to drawing direction. Pearlite have turned into fibrous microstructure after heavily drawing. Comparing microstructure of wires with and without reserved texture, as figure 2c and 2d show there were no visible different when at ε=0.5. There were more cementite lamella bent or fractured in wire without reserved texture than with one as figure 2e, 2f, 2g and 2h.

(a) ε=0 (b) ε=0

(c) ε=0.5 (d) ε=0.5

(e) ε=1.7 (f) ε=1.7

(g) ε=3 (h) ε=3

Fig.2 Microstructure of steel Wires after Cold Drawing 1st Column: With reserved Texture 2nd Column: Without Reserved Texture

Texture Analysis

Change of intensity of <110> texture in two wires were shown in figure 3. Figure 3 shows that intensity of <110> texture of wires increase with the increase of true strain from 0 to 1.69. Intensity of <110> texture of wire with reserved texture is higher than the without one. The evolution of

α-ferrite's texture in the two wires drawn to different strains was measured by using inverse pole figure measured in the drawn direction corresponding to the true strain of 0,0.49,0.93,1.69 as shown in figure 4. Comparing inverse pole figure of two wires, the α-ferrite's orientation in wire with reserved texture turn into <110> pole more quickly.

Fig.4 Inverse Pole Figure of Two Wires in Different Strains. The First Line is the Wire With Reserved Texture and Second Line is the Wire with no Reserved Texture

Discussion

Reserved texture improve working hardening rate of pearlitic wire. Intensity of <110> texture in wire with reserved texture are stronger than the without one at all strain. Studies[3,6,11-12] have demonstrated that closely orientation of pearlite improve the mechanical properties. Microstructure of pearlite is composite structures of two phase: α-fe and cementite. Deformation of this two phase are more closely to composite materials of laminate structure. α-fe(soft phase) deform more than cementite(hard phase) when deformation was not heavily. If α-fe's <110> orientation were not in or near to the drawing direction the pearlitic colony must rotate to the direction. When α-fe's <110> orientation were nearly perpendicular to the drawing direction rotation will be difficulty, pearlitic colony were subjected high shear stresses. Cementite lamellae may bent or fracture. Fractured cementite cause stress concentration and become micro-crack resource when wire was subjected stresses.

Reserved texture make intensity of <110> fiber texture higher during drawing. Higher <110> textural intensity means there are more pearlitic α-fe's <110> orientation are closely to drawing direction. Less pearlite need rotate to deform, less cementite lamellae may bent or fracture and more pearlite may get thinning. It reduce shear deformation and improve the hard working rate of pearlitic wire.

Conclusion

1) Reserved <110> texture improve working hardening rate of pearlitic wire. After drawing, tensile strength of wire with reserved texture are higher than the without one at all strains.

2) Intensity of <110> texture of wire with reserved texture is higher than wire without reserved texture at all strains. It indicated orientation of pearlite near to drawing direction and reduce shear deformation of pearlite.

Keywords: Cryogenic Steels; 9%Ni Steel; structural studies; mechanical tests.

Abstract: The growing needs for energy combined with the will to reduce CO_2 emissions lead to the increase of the demand for liquefied natural gas (LNG), which will be stably available for many decades to come. Cryogenic materials used for the manufacture of the inner tanks for LNG storage are composed of 9% Ni steel plates with excellent low-temperature toughness, great ductility and crack resistance for a high safety level. To guarantee the reliability and safe operation of large-scale metallic structures exposed to cryogenic temperatures for extended periods, it is important to evaluate structural and mechanical properties of the metal base as well as the welded zone in their own operating conditions in order to prevent damages that could occur.

Introduction

The increase in energy consumption, as well as the predictable lack of oil and the rise of extraction costs, encourage manufacturers to find new energy sources. Liquefied natural gas (LNG) that can replace oil and allow the transition to a low carbon economy is one of them. Thus the use of liquefied natural gas as a clean energy source from the point of view of global environment and installation of LNG terminals are growing rapidly [1].

LNG represents the ideal solution to transport natural gas coming from distant fields towards markets where it is not feasible to construct a pipeline. LNG provides several advantages: It is a relatively clean energy neither toxic and non-corrosive, practical, with a reasonable calorific value, and finally approximately twice lighter than water. The environmental qualities of natural gas make it a fuel of choice. In vehicle fleets where the evaporation of LNG can be controlled appropriately, the LNG storage provides benefits over compressed natural gas in terms of compactness and tanks weight as well as flow of filling [1, 2].

Cryogenic materials used for the manufacture of the tanks for Liquefied Natural Gas (LNG) need to remain tough, ductile and crack resistant with a high level of safety. Steels with specific mechanical properties are required [3]. Thus The 9% Ni steel has been widely used around the

world as a material for the inner walls of LNG-tanks and pipelines because of its excellent cryogenic fracture toughness. The brittle fracture properties of the steel, which are closely related to the safety of structures, among others, has been extensively studied, and as a result, it has been made clear that the steel and its welded joints have sufficiently good brittle fracture properties for application to above-ground LNG tanks[3-7].

In this work, the effects of cyclic fatigue at very low temperature on mechanical and structural properties of 9% Ni steel were investigated. The structure and the chemical composition of the samples were determined by means of several techniques such as: Inductive Coupled Plasma – Atomic Emission Spectroscopy (ICP-AES), X-ray Fluorescence, X-ray Diffraction at low temperature, High Energy Synchrotron X-ray diffraction, ^{57}Fe Mossbauer Spectroscopy and Electron Paramagnetic Resonance. Mechanical tests were carried out at room temperature and at –196°C to evaluate the degradations of the mechanical properties of the 9% Ni steel, and its weld joints. Then, the topography of fractured surfaces was observed by Scanning Electron Microscope to identify the fracture modes. X-ray diffraction analysis was employed to reveal phase changes which could promote the degradation in the mechanical properties of these materials.

Materials and experimental procedures

The studied material is the 9% Ni steel (base and weld metals). This material is commercial grades used for LNG storage tanks supplied by Salzgitter Mannesmann (France).

The chemical compositions of 9% Ni steel base metal established on casting according to the material certification sheets supplied by the manufacturers as well as that on product determined by ICP AES (Inductively coupled plasma Atomic emission spectroscopy), X ray Fluorescence, Inert Gas fusion Infrared and thermal conductivity detection (LECO TC 436 used to determine O_2 and N_2) and (LECO CS 444 used to determine C and S) are given in Table 1.

For the cryogenic 9% Ni steel, the steel plates are processed by Quenching and Tempering (QT) heat treatment X8Ni9_QT640 in its initial state (according to the standard NF EN 10028-4): Hardening at 800°C; Soaking time: 1min. /mm, (minimum 15 minutes) then water Quenching and finally tempering at 600°C; Soaking time: 1min. /mm, (minimum 30 minutes) then air cooling.

The microstructure of the steel is a tempered martensite with residual austenite with high Ni-content. The presence of these phases in this material was confirmed by X-ray diffraction analyses (Fig. 1) (martensite peaks noted as M and austenite peaks noted as A), and ^{57}Fe Mossbauer Spectroscopy (Fig. 2).

Nine percent Ni steel for LNG storage tank are invariably joined by welding. The welding of these materials for LNG applications determines for a great deal the structural integrity.

The 9% Ni steel plates were welded with stick electrodes (SMAW). Consumable is a high nickel alloy ENi–Cr–Mo6 used for its ductility and its thermal expansion capacity.

The X-ray spectrum of 9% Ni steel weld metal (Fig. 1) shows an austenitic microstructure due to the high nickel content alloy used as a filler metal for the welding.

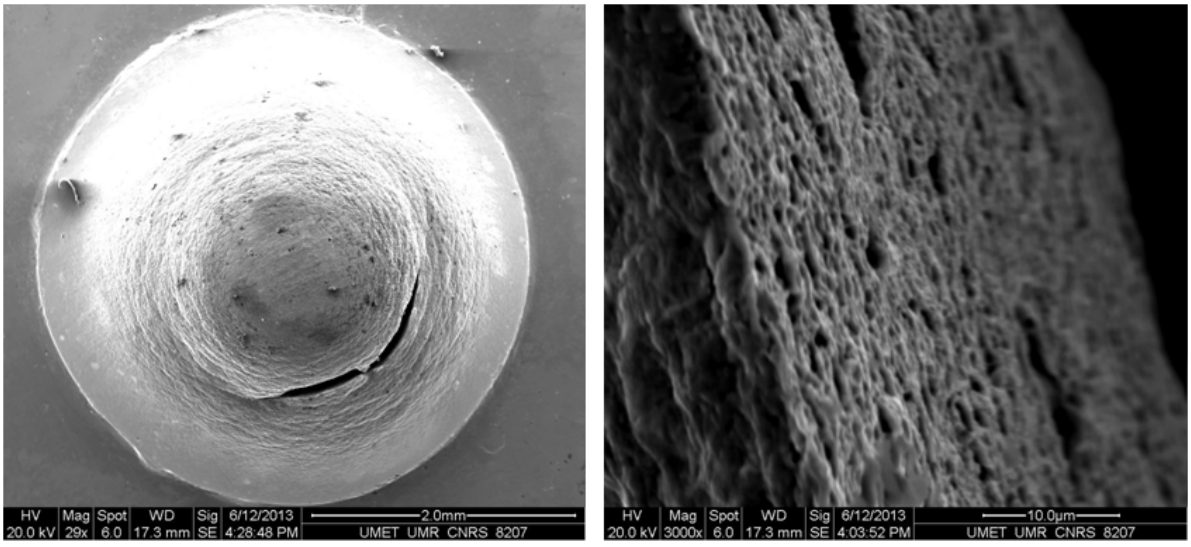
The Small Punch Test (SPT) is a non-standard mechanical test. It has been developed to obtain mechanical properties (yield strength, ultimate strength, elongation, fracture energy, and toughness) of small regions, the quantity of which is limited or has been reduced (e.g. irradiated material). This type of test became attractive and provided interesting information on the deformation behavior, on the fracture, as well as on ductile to brittle transition or evolution of the mechanical properties due to the temperature, to an environment or to ageing [8].



The SPT were performed at room T and at -196°C using an (MTS DY 35) tension / compression electro mechanical machine with a controlled cross-head speed of 0.5 mm/min. Load–cross-head displacement curves were recorded during the tests. The specimen has a squared shape (8mm). Before testing, the sample surfaces were mechanically polished with an automatic polisher (Phoenix 4000) using SiC paper up to 1200 grade until 500 (±20) μm thickness and a diamond suspension in an aqueous solution, in order to avoid effects due to the roughness of the surface. After mechanical tests, scanning electron microscope (SEM) observations were performed on a LEO 438VP SEM to determine the fracture appearance of the specimens. The fracture surfaces contain dimples typical of ductile rupture at room T and -196°C (Fig. 3). Furthermore, for all SPT specimens, cracking is circular or semicircular. These results are in agreement with a cracking mechanism due to the membrane stretching and with the observations mentioned for ductile fracture behavior [9–11].

The temperature decrease from room temperature to -196 ° C provides an improvement in the mechanical properties of the 9% Ni steel, without affecting its ductility.

No changes were observed on the mechanical and structural properties of 9%Ni steels after 6000 cycles of mechanical fatigue with a frequency of 1Hz at room T and at -196°C.

(a)

(b)

Fig. 3 SEM micrographs showing the fracture surfaces of the samples at room T (a) and at -196°C (b)

Summary

The 9% Ni steel is used in the cryogenic applications because of its good toughness at low temperature. Its mechanical properties increase with decreasing temperature, due to a greater consolidation.All tensile tests and small punch tests curves, as well as SEM observations, are in agreement with a ductile fracture behavior at room T as well as at -196°C.

Keywords: Frequency Domain Spectroscopy, Transformer, Insulation, Relaxation function

Abstract: Relaxation function can well reflect the microscopic polarization mechanism of dielectric. In order to analyze the influence of moisture and temperature on relaxation function of oil-paper insulation, building a physical model of the oil-paper insulation system containing moisture and obtaining the expression of relaxation function. Setting up a testing device for the oil paper insulation dielectric spectroscopy in the laboratory, the parameter values of relaxation function expression were obtained according to test result by Fourier inverse transformation. The results show that the relaxation function containing three relaxation factors are more suited for the relaxation of oil-paper insulation containing moisture content and microscopic polarization mechanism, moisture and temperature have a significant effect on relaxation function.

Introduction

Oil paper insulation is the main insulation systems for traction transformer, and the micro water severely reduces the insulation performance of traction transformer, this will bring huge hidden trouble on rail transportation especially the safe operation of high-speed railway[1]. However, the traditional test method of traction transformer operation process is too complicated, and the measurement result varies. In recent years, using the frequency domain dielectric spectroscopy (FDS, Frequency Domain Spectroscopy) in evaluation of oil paper moisture content has been studied. However, researches focus on the content of moisture, temperature effects on the FDS characteristic parameters, but few reports are about the explanation of influence mechanism [2-4]. To analyze the mechanism of moisture and temperature effects on the dielectric spectrum, the equivalent physical model must be constructed with the micro water in oil paper insulation composite system. At present, the analysis on test results of the dielectric theory of Debye model, Cole-Cole model has been widely used, but it has limitation [5].

For example, the dielectric spectrum of Debye model is mainly applied to the polar liquid and solid medium, and it is only suitable for single phase insulation system [6]. To get general frequency-domain analysis methods, the expression of relaxation function must be first established. However, relaxation function is related to the composition, structure and environmental factors such as temperature and material, so it is not easy to find the general expression of [7] suitable for all occasions. FFT can decompose any real periodic function into the sum of sinusoidal signal with higher and higher frequency domain. Therefore, the mathematical properties of FFT transform could be used to obtain the relaxation function, through the combination of numerical analysis and FFT inverter commutation.

Theoretical basis

Relaxation function

In the flat electrode filled with a dielectric constant of ε, two ends are imposed of a sinusoidal voltage signal E (T), degree of dielectric polarization and loss in different frequency AC electric field can be described with micro relaxation function. Macroscopic representation is a complex dielectric constant (or complex capacitance). Document [6] establishes the relationship between the two, as is shown in the type (1) and (2).

$$\varepsilon'(\omega) = \varepsilon_\infty + (\varepsilon_s - \varepsilon_\infty)\int_0^\infty \varphi(t)\cos\omega t dt \quad (1)$$

$$\varepsilon'(\omega) = (\varepsilon_s - \varepsilon_\infty)\int_0^\infty \varphi(t)\sin\omega t dt \quad (2)$$

In which, ε_s is static relative permittivity, ε_∞ is the optical dielectric constant, ε' is the real part of permittivity, representing polarizability of materials, namely, the relative dielectric constant; ε'' is the imaginary part of complex permittivity, representing dielectric loss of materials. $\varphi(t)$ is the time expression of the relaxation function , ε' and ε'' are dependent on the function. By using the Fourier transform, the test results in the frequency domain can be transformed in time domain, thus the relaxation function can be obtained.

The physical model of oil -water composite system

Head pressure: 10MPa; Column Temperature: 40℃initially, 10minites later, raise to 60℃at speed of 5℃/min; Carrier Gas Flow Rate: 10ml/min; Injection Volume: 1ml in quantitative tube.

Oil paper insulation system is a two-phase insulation system, which can be regarded as combination of a plurality of capacitor and resistor. If the system contains "free water", it can be equivalent to a three-phase heterogeneous model, as shown in figure 1. The physical model consists of equivalent sery-wounded circuit containing three [C-G] loops; it has three relaxations, from which the corresponding relaxation function from the physical model can be concluded as:

$$\varphi(t) = \frac{1}{\tau_1}e^{-k_1 t} + \frac{1}{\tau_2}e^{-k_2 t} + \frac{1}{\tau_3}e^{-k_3 t} \quad (3)$$

In which τ_1, τ_2, τ_3 respectively represent the insulating paper, transformer oil and water relaxation time.

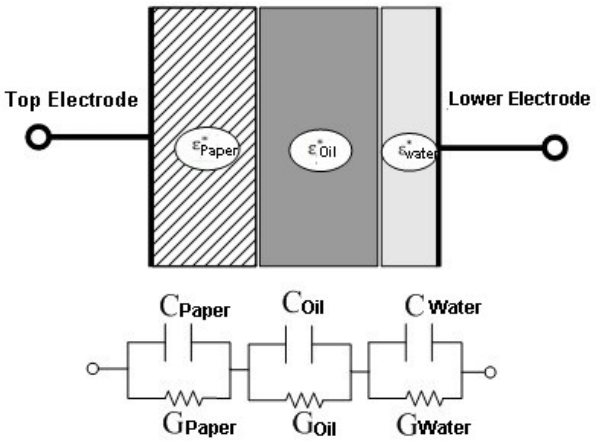

Fig.1The equivalent three-phase insulation system model of oil, paper and water

Experiment

Experimental materials

Insulating paper: 0.3mm ordinary cellulose insulation paper

Insulating oil: 25# naphthenic transformer oil

Experimental procedures

After shaping insulating paper (140mm*140mm), put it in the "WD841-2" type electric blast oven; keep it for 2 to 3 days at constant temperature of 120 ℃and dry it. Then put sample indoors, with the purpose of natural absorption of moisture in the air. By Karl Fisher titration, insulating paper samples with water content 0.98%, 2.03%,3.11% and 4.16%can be obtained, and then place them in transformer oil (12ppm less than the water content in oil). When micro water balance in oil paper combination insulation is reached, conduct FDS test.

Test results and analysis

Effect of micro water on the relaxation function

In order to study the effect of micro water on the relaxation function, oil paper insulation electric frequency spectrum with micro water content 0.98%, 2.03%, of 3.11% and 4.16% are tested below 50 ℃, as shown in Figure 3.

By using the FFT transform, curve fitting of the real and imaginary parts of the complex dielectric constant , and then obtain relaxation function through the FFT transform, the parameters of a value in an expression are shown in table 1. Put the relaxation function into type (1) and (2), get the function expression of frequency domain $\varepsilon'(\omega)$ and $\varepsilon''(\omega)$, as shown in Figure 3 (solid line). As can be seen from the graph $\varepsilon'(\omega)$ and $\varepsilon''(\omega)$ results are agreed with the test value, indicating that the relaxation function expression constructed by physical model can reflect dielectric relaxation in oil paper insulation system containing micro water. As can be seen from table 1, with the increase of water content, three kinds of dielectric relaxation time increase, that is mainly because under applied electric field. There is a close relationship between strength and interfacial water molecules concentration polarization, the higher moisture content is , stronger ability of induced polarization of oil and paper, interfacial polarization strength increases, the corresponding relaxation time is longer. When micro water content is the same, because the water molecules has the advantages of small size, polarization ability is high, under the action of the electric field, polarization is very likely to happen., relaxation time （τ_3） is minimum ; cellulose molecules are polar molecules, but because of large volume, polarization requires a long time, the relaxation time （τ_1） is slightly longer; transformer oil is a weak polar molecules, polarization is less influenced by electric field, therefore, relaxation time （τ_2） is maximum.

Tab.1Parameter values of relaxation function at different moisture content

Water	τ_1	k_1	τ_2	k_2	τ_3	k_3	R^2
0.98%	17.2622	1.401	159.9744	2.372	0.0656	0.0116	0.9836
2.03%	42.2297	1.808	607.1645	2.215	0.0859	0.1427	0.9921
3.11%	853.2423	2.852	17241.379	3.092	0.1289	0.3278	0.9894
4.26%	4545.454	3.257	31250.000	2.938	0.2558	0.2705	0.9833

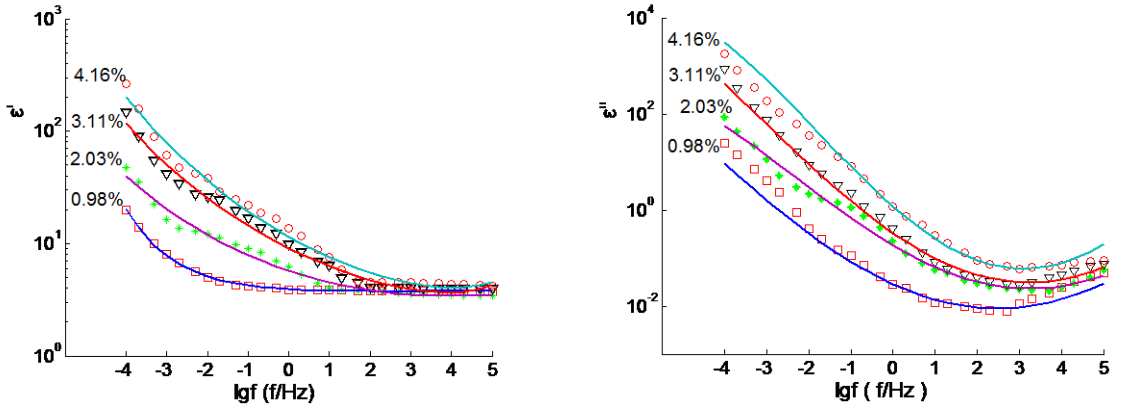

Fig.2Test value and calculated value of ε' and ε'' at different moisture content

Effect of temperature on the relaxation function

In order to study the influence of temperature on the relaxation function, dielectric power spectrum of oil paper insulation is tested under the temperature of 10 ℃, 30 ℃, 50 ℃, 70 ℃,when the micro water content of 2.03%, as shown in Figure 4. Using the same principle in 3.1, the relaxation function values can be obtained at different temperatures (as shown in Table 2) and the function expression the frequency domain $\varepsilon'(\omega)$ and $\varepsilon''(\omega)$ could also be obtained. (As shown in Figure 4 (solid line)). We can see from table 2, oil and paper relaxation time （τ_1 and τ_2） increases

as the temperature raises, the water molecular relaxation time （τ_3） decreases with the increase of temperature. That is mainly because relationship between the dielectric relaxation strength （$\Delta\varepsilon$） and temperature (T) is as shown in formula (4):

$$\Delta\varepsilon=\frac{a}{T}g_r(T)\mu_{eff}^2 \tag{4}$$

In which, A is a parameter independent of temperature, $g_r(T)$ is the strength of molecular interactions, and is related to the temperature, μ eff is the effective dipole moment, the temperature has little influence on it. Transformer oil molecules and cellulose have large volume, in a certain temperature range; we can take B and C as a fixed value. Therefore, with the increase of temperature, the oil molecules and molecules of cellulose transformer dielectric relaxation strength is enhanced, the corresponding relaxation time decreases. Water molecules is with small size, and strong polarization ability, when the temperature increases, thermal motion of molecules intensifies, thus it weakens the interaction forces between molecules, i.e. $g_r(T)$ is reduced, leading to water dielectric relaxation strength weakened, but increased the relaxation time.

Tab.2Parameter values of relaxation function at different temperature

Temp.	τ_1	k_1	τ_2	k_2	τ_3	k_3	R^2
10℃	352.1582	1.296	2710.8326	0.01247	0.0084	0.0239	0.9965
30℃	107.9132	0.4946	1429.4820	0.02085	0.0605	0.0219	0.9863
50℃	42.2297	0.808	607.1645	2.215	0.0859	0.1427	0.9804
70℃	4.6514	0.2126	493.2861	0.3294	0.1036	0.2261	0.9772

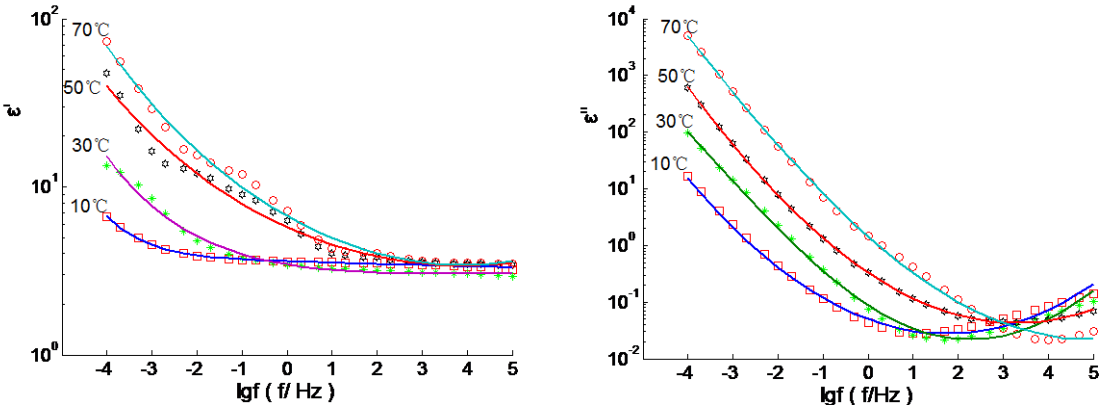

Fig.3 Test value and calculated value of ε' and ε'' at different temperature

Conclusion

(1) The expression of relaxation function established from three relaxations, can reflect the traction transformer oil paper insulation relaxation containing water and microscopic polarization mechanism, an association exists between the relaxation function and the micro water content and temperature.

(2) In the same temperature, insulation paper, transformer oil and water relaxation time gradually increase with increasing water content.

(3) When micro water content in oil paper insulation is the same, insulating paper and transformer oil relaxation time decreases with the increase of temperature, moisture of the relaxation time increases with the increase of temperature.

Keywords: Aluminum alloy.Sacrificial anode.Microstructure.Electrochemical characteristics.

Abstract: The influence of Si on the corrosion behaviour of Al-Zn-In-Mg-Ti alloy was investigated by the microstructure observation and electrochemical measurements in order to improve its corrosion non-uniform and electrochemical properties. The results show that the current efficiency of Al-5Zn-0.02In-1Mg-0.05Ti-0.09Si (wt.%) alloy corroded uniformly reaches 92%. It presents the property of low resistance and high capacitance. While the Si content exceeds 0.12 wt.%, the resistance of active dissolution increases gradually. The current efficiency decreases obviously. The results indicate that the electrochemical characteristics and corrosion uniformity can be improved significantly after adding 0.09 wt.% Si into Al-Zn-In-Mg-Ti alloy.

Introduction

Nowadays, aluminum alloy sacrificial anode materials have been widely used in anti-corrosion protections for all kinds of ships, oil platforms and subsea pipelines [1], because it is light, cheap and with large capacity. Aluminum ingot usually contains many kinds of impurities, such as iron, silicon and copper, etc. Some researchers hold that these impurity elements have negative influences on the performance of aluminum alloy anode [2,3]. Because of the excellent comprehensive performance in seawater and no need of heat treatment, Al-Zn-In series of alloying became one of the most popular materials for aluminum alloy sacrificial anode [4,5]. And it has become an arrestive research to improve the electrochemical properties of Al-Zn-In-Mg-Ti alloy by adding different elements [6,7]. Si is the most common impurity in Al-Zn-In series anode. The solubility of Si is very small in aluminum and it is nearly zero at room temperature. There is only few Si in the solid solution, most of them exists in the second phases or forms intermetallic compounds with other impurity elements. Si impurities bring cathode phases which aggravate the hydrogen evolution self-corrosion and reduce the current efficiency of aluminum alloy sacrificial anode. So, Ponche, Horst [8] and Sakano [9] have defined a primary limitation on Si impurity content in Al-Zn-In series anode through their study. And some corresponding provisions have been made for Si impurity content in Al-Zn-In series anodes used in seawater [10,11] at home and abroad. But not all impurities are harmful, they also have some advantage. Reduction in density and thermal expansion coefficient, improvement in hardness, ambient temperature mechanical properties and wear resistance along with an excellent castability can be achieved by addition of Si to aluminum alloy [12-14]. The aim of the present work is to improve the corrosion non-uniformity and electrochemical performance of Al-Zn-In-Mg-Ti anode by adding a suitable Si content.

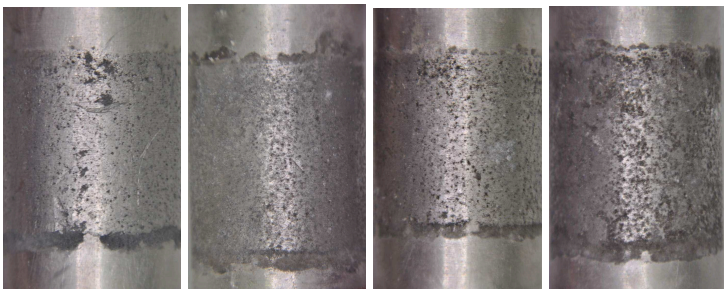
Experimental materials and Methods

According to aluminum ingots' impurity content in the preparation of Al-Zn-In series sacrificial anode, Al-5Zn-0.02In-1Mg-0.05Ti-XSi-0.10Fe-0.01Cu (wt.%) was designed and applied, the values of X in 1#-4# samples were 0.06, 0.09, 0.12, 0.15 (wt.%).

According to DET NORSKE VERITAS (DNV) RP B401 "Cathodic Protection Design" [11], the accelerated experiment that can test and measurement the work potential and the actual capacitance of the sacrificial anode was applied. The corroded samples were observed by scanning electron microscope (SEM) after constant potential corrosion applied -0.9 V at 30 ℃ for 3 h. EIS measurements were carried out with three electrodes system by using VMP3 workstation. Working electrode was aluminum alloy, reference electrode was saturated calomel electrode (SCE), auxiliary electrode was Pt electrode and working area was 1 cm^2. Testing medium was the natural seawater

from Bohai Sea, temperature was 22 ± 1℃. For electrochemical impedance spectroscopy (EIS) measurement, samples were immersed for 48 h and expressed 10 mV disturbances in the frequency range of 10^{-1}-10^{5} Hz.

Results and discussion



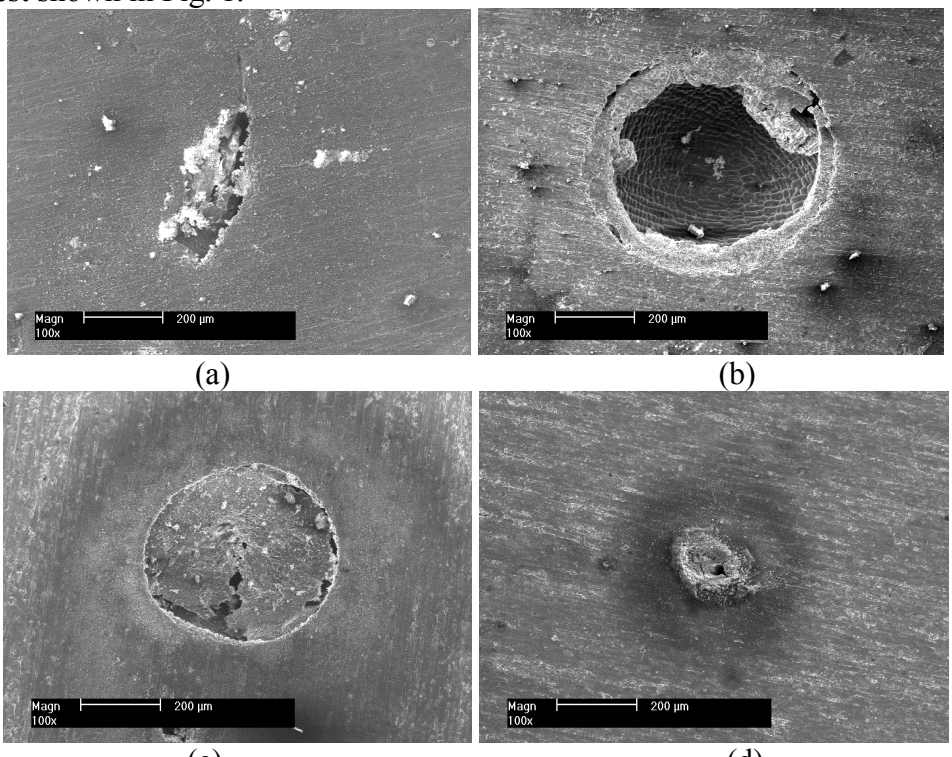
Anode current efficiency

Table 1 presents electrochemical performances of 1#-4# samples. The working potential of sample 1# was negative, but the actual capacitance and current efficiency were only 2364.05 $A \cdot h \cdot kg^{-1}$ and 82.43% because of microstructure non-uniformity. Many shiny particles considered to be aluminum by energy spectrum test were found in sample 1# corrosion products. A mass of mechanical loss leaded to the lowest current efficiency. The potential of sample 2# fluctuated slightly. The actual capacitance was 2640.50 $A \cdot h \cdot kg^{-1}$ and the current efficiency reached 92.05%. While the Si content exceeded 0.12 wt.%, the anode current efficiency decreased obviously. Si can refine grains and trap Fe impurities to form Al_2Fe_3Si which is harmless to anode's potential. Added Si as non-spontaneous nucleations which fine grains in crystallization process can reduce the current efficiency loss caused by grains dropping. The activation is from active elements as solid solution in dissolution process. The finer grains are, the more uniformly active elements can distribute in the alloy, which indicates that the aluminum anode has dissolved more uniformly. The moderate addition of Si is helpful to reduce galvanic corrosion and the anode potential to a certain extent, which means that the cathodic protection property will be improved [15]. Due to the low solubility of Si in aluminum alloy, the excess Si segregates on the grain boundaries is in free status, which causes the grain-boundary attack in the poor Si region near grain boundaries. Besides, the excess Si could form the cathode phase (relative to the aluminum substrate) with Fe impurities. The difference of electrochemical properties lead to alloy self-corrosion, which reduce the anode efficiency [16]. As indicated above, aluminum alloy can achieve high anode current efficiency by adding 0.09 wt.% Si.

The corrosion morphology images of samples are shown in Fig. 1. Corrosion products which adhered to sacrificial anodes almost fell off after acid etching. Sample 1# presented non-uniform corrosion obviously. As Si increases, sample 2# had a general corrosion tendency. The depth and width of pits were uniform and moderate on sample 2# surface which had excellent corrosion feature. There were some deeper pits and a few severe corrosion areas on sample 3# surface. Its integral dissolution morphology was good. The pits of sample 4# whose surface was uneven were further deeper, which indicates that non-uniform corrosion had been intensified. To conclude, a moderate addition of Si can improve the casting property of aluminum alloy and reduce casting defects. Sample 4# presented the excellent dissolution morphology and continuous protection performance by adding 0.09 wt.% Si. Not all impurities are harmful, they also have some advantage. Si can raise the recrystallization temperature and refine grains in high purity aluminum [12,13,17]. It can also improve the mechanical property at high temperature (hot strength) and wear resistance of aluminum alloy [18], etc. The use-type of sacrificial anode material is as-cast that has defects appear usually. These defects lead to the degradation of electrochemical performance and the non-uniform dissolution on alloy surface. Both the crystallization latent heat and the heat release of Si are big. Added Si can bring the excellent alloying liquidity that makes alloying elements having enough time to dissolve into matrix. The small shrinkage and expansion coefficient of Si cause defects such as shrinkage porosity and shrinkage cavity, etc., which indicates the casting property and microstructure uniformity of aluminum alloy are improved. It becomes a practical way to improve the comprehensive mechanical properties of Al-Zn-In-Mg-Ti anode by adding 0.09 wt.% Si.

TABLE 1 ELECTROCHEMICAL PERFORMANCES OF 1#-4# SAMPLES

No.	Working potential ($-V_{SCE}$)	Open circuit potential ($-V_{SCE}$)	Actual capacitance ($A \cdot h \cdot kg^{-1}$)	Current efficiency (%)
1	0.928~0.947	0.942	2364.05	82.43
2	0.918~0.935	0.938	2640.50	92.05
3	0.919~0.933	0.936	2618.15	91.26
4	0.912~0.942	0.933	2580.75	89.94



(a) (b) (c) (d)

Fig. 1 Sample 1#-4# macrophotography(a)Sample 1# (b)Sample 2# (c)Sample 3# (d)Sample 4#

Corrosion Morphology analysis

The SEM pictures are shown in Fig. 2. It is found that the crevice corrosion appeared and grains fell off mechanically on the sample 1# surface because of many defects of organization and structure. Owning to the good microstructure uniformity and dissolution-precipitation mechanism, the pit hole of sample 2# expanded to surrounding gradually, which means that the anode has a tendency toward general dissolution by adding 0.09 wt.% Si. Due to the excess Si blocking the formation of amalgam, the pore size of sample 3# decreased slightly with respect to that of sample 2#. And the orifice was covered with the passive film formed by corrosion products and oxide, which indicates that the dissolution of sample 3# tended to inside. However, the deep pit whose orifice was narrow and small appeared on the sample 4# surface. This phenomenon showed that the excess Si impurities stop the dissolution-precipitation proceeding continuously. The pitting corrosion tendency of sample 4# was enhanced, and the ability of uniform corrosion declines. Above results were corresponding to those of accelerated test shown in Fig. 1.

EIS measurements

Nyquist graphs of 1#-4# samples in seawater are shown in Fig. 3. Aluminum alloy anodes in seawater present the single capacitive reactance arcs which are squashed arcs in the high frequency region and linear in the low frequency region. The curves show the change of resistance in the high frequency region and the electrochemical reaction charge transferring resistance's change. As Si content increases, the diameters of capacitive reactance arc turn to long, which indicates that the impedance of electrochemical reaction increases. So the impedances of samples increase and the electrochemical activity of samples are weakened.

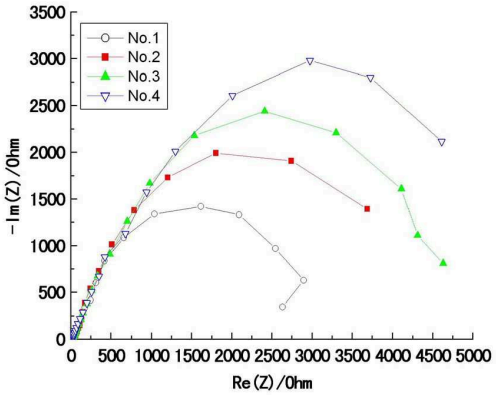

Fig. 3 EIS Nyquist diagram of 1#-4# samples

In order to get more information from these EIS curves, we adopted the equivalent circuit shown in Fig. 4 to imitate the EIS of aluminum alloys [19]. The alloy surface is covered with Al_2O_3 oxide film before being soaked in seawater. R_s is solution resistance, CPE_1 and R_1 represent the capacitance and resistance of electric double layer which are formed by the deposition of Zn and In on the alloy surface, CPE_2 and R_2 represent the capacitance and resistance of electric double layer which are formed by the passivation film on the alloy surface in the solution. Capacitance is replaced by phase components due to the strong dispersion effect of EIS in seawater.

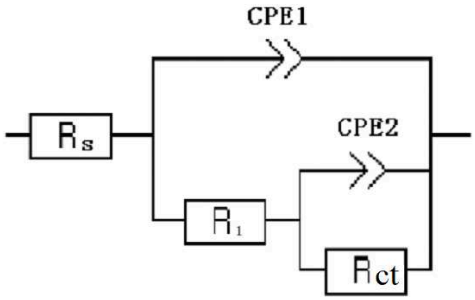

Fig. 4 Fitting equivalent circuit of EIS

The values of CPE, Q and n have the following relation,

$$CPE = [Q(j\omega)^n]^{-1}. \quad (1)$$

The value of Q is interrelated to the state of electrode surface or the species of electric active substance. Jω is the composite variable of sinusoidal disturbances, $j = \sqrt{-1}$, ω=2πf. The value of n (0~1) represents the index of CPE, When n=1, CPE is the ideal pure capacitance.

Table 2 shows the results of fitting parameters in the equivalent circuit. The results show that the value of R_s was between 19.87 $\Omega \cdot cm^2$ and 21.16 $\Omega \cdot cm^2$, the value of R_{ct} increased from 2862 $\Omega \cdot cm^2$ to 5889 $\Omega \cdot cm^2$, while the double-layer capacitance of passive film (Q_2) decreased from 7.435×10^{-5} $F \cdot cm^{-2}$ to 3.274×10^{-5} $F \cdot cm^{-2}$. It is found that along with the increase of Si content, the charge transfer resistances increase and the values of double-layer capacitances decrease clearly. The value of n is close to one which means that the phase angle element is close to capacitance. Due to the low values of Q, the total impedance of equivalent circuit equal to R_{ct} approximately. The resistance of electric double layer formed by the deposition of Zn and In on the alloy surface (R_1) and the capacitance of electric double layer from matrix and solution interface (Q_1) have the same tendency like R_{ct} and Q_2. The results show that when Si content 0.09 wt.%, the anode presents the property of low resistance and high capacitance, which has positive influence on improving the electric capacity of anode.

TABLE 2 COMPONENT VALUES OF FITTING CIRCUIT

No.	R_s $\Omega \cdot cm^2$	R_1 $\Omega \cdot cm^2$	Q_1 $F \cdot cm^{-2}$	n_1	R_{ct} $\Omega \cdot cm^2$	Q_2 $F \cdot cm^{-2}$	n_2
1	21.04	76.38	4.016×10^{-5}	0.956	2862	7.435×10^{-5}	0.9257
2	20.92	118.9	2.127×10^{-5}	0.9887	3722	6.486×10^{-5}	1
3	21.16	124.2	1.415×10^{-5}	0.9568	4586	5.201×10^{-5}	0.9549
4	19.87	194	0.964×10^{-5}	0.9895	5889	3.274×10^{-5}	0.8897

Conclusions

The Al-5Zn-0.02In-1Mg-0.05Ti-0.09Si (wt.%) alloy has excellent anode properties. Its working potentials are between -0.918 V~-0.935 V and current efficiency reaches 92%. It has good dissolution morphology and presents the property of low resistance and high capacitance. While the Si content exceeds 0.12 wt.%, the current efficiency decreases obviously. The results reveal that the microstructure, electrochemical characteristics and corrosion uniformity can be improved significantly after adding 0.09 wt.% Si into Al-Zn-In-Mg-Ti alloy.

The Application of Green Materials in Product Packaging Design

Ouyang Chaoying, Li Lin, Xiong Yajie, Nie Xiaoli

School Of Arts & Design.HuBei University Of Technology,China

oycyen 001@126.com

Keywords: natural, green materials, product packaging design

Abstract. Packaging requirements for products are increasingly high as society advances , the development of logistics. This paper revolves around the green material, through the selection of green materials and design concepts, analyzed the application of green materials in product design and its development trend. Through the knowledge of advanced materials, the better product design that meet market needs could be created, the value of the material could be unfolded, the “Green Life” period, the new style and new material of design could be created.

Introdution

According to "Kao Gong Ji" recorded: design to be harmonious with time, environment, material, and art. We can find the thought that represent beauty with the property and feature of material has already exist since ancient times. Human beings through the stone age, pottery age, bronze age and the iron age, entered the era of contemporary synthetic materials, materials has become an indispensable and important part of human survival and life, has become an important factor to measure the development level of social science and technology.

In the traditional product design, the less consider impact on the environment on the material selection, therefore in the process of production, consumption has certain harm on the environment. So in such an era of rapid development of science and technology , what material is wonderful we think of ?Where is the way of packaging design and product design material?

Green Materials And Design Concepts

Green materials refers to the materials in raw materials taken , product manufacturing use and recycling and waste processing and other aspects which helpful to human health and can harmonious coexistence with ecological environment of the environment. They should have a purifying absorption function and health-promoting functions. Green material was first time proposed on 1988 First International Materials Conference, and was designated as one of the most important materials human to realize in next century.

Materials which are suitable for green product design all be considered as green materials, also including those although have harm to the human and the environment, but can take appropriate measures to reduce or eliminate the materials and manufactured goods. Its main concepts including the advanced nature of the material itself (high quality production of low energy consumption), the safety of the production process, the rationality of the materials used (saving, recycling), and accord with the requirement of modern engineering, etc. Green material is the key point of green product design. Green material require people with environment awareness, on the one hand, reform the existing material, make it has good coordination with environment; on the other hand the development of new materials, which was used to purify the environment, environmental restoration, or has good comprehensive performance and environmental coordination.

Also known as ecological design, green design aims to balance the human demand and the relationship between the supply of the natural environment. The most important methodology of green design is to emphasize the “product life cycle” ideas, make product with recyclability, removable, maintainable, reusable, and other products of environmental attributes. Green design is not only a technical consideration, more importantly it is a change of the concept. It requires stylist to abandon that too much emphasis on product on the appearance of novelty, but focus on innovation with true sense, and with a more responsible approach to create a product form, and use a more concise, lasting modeling make the products as much as possible to prolong its service life.

The Status Of The Domestic Packaging Design

Packaging requirements for products are increasingly high as society advances, the development of logistics. On the one hand to protect goods from damage, easy to transport and storage, on the other hand require beautiful and easy to sell commodity packaging, and even to some extent become the external form of competition of the commodity, and because of the luxury packaging, make commodity packaging gradually become the main performance of commodity value, so the packaging costs rise, prices rise, the vast majority of the packaging has not been spared from the garbage after use. According to data statistics, every year in our country about 16 million ton producing waste, the main is plastic packaging products of waste, which waste each year up to 1 million ton, including plastic lunch box, cup dish, foaming material, plastic bottles, all kinds of candy, food packaging, and all kinds of plastic bags, etc. According to experts, the white garbage will be retained for quite a long time also won't disappear in the earth's surface. So how to reduce waste, how to make good use of waste, this is a status and problems of domestic packaging.

The current domestic market became a hodgepodge of product packaging. They are proud of conceptualization of foreign products mimic, the supermarket full of beautiful things in eyes of different styles of packaging products, but on behalf of the Chinese nation style products and rarely lack of personality.

The Application And Development Trend Of Green Materials In The Product Packaging Design

The Material On Design Return To Nature

First of all, the material on design can choose natural biological material, such as use paper, wood, bamboo weaving materials, hemp, cotton, willow, reed and the stem, rice straw, wheat straw and other crops for packaging. They're very easy to break down in the natural environment, never polluting the ecological environment, renewable, and the cost is low.

For example, a Swiss stylist designed a white gift paper bag, in the process of paper making will join in the seeds of trees which make the paper itself can break down after abandoning, and the seeds inside still have a chance to take root, sprout, grow up in the soil.

Muji clothing material all adopt organic cotton, noil, linen, wool and other natural materials and recycled materials. Organic cotton has no chemical drug residues in the production and process, all natural environmental protection in planting production process. Noil is the falling short fiber in the processing of cotton, is the recycling of natural materials. As shown in figure 1 is the cotton fabric design handbags.

Secondly, we can develop in the direction of the use of edible packaging materials on the material selection. For its abundant raw materials, edible, harmless or even beneficial to human body, the characteristics of a certain intensity, edible packaging materials has rapid development in recent years. It has been widely used in food, medicine packaging. Such as Germany invented a cup made of starch which in the liquid will not melt, and this kind of cup can eat together with the cup beverage, but won't produce too much heat. Another example is the cone we usually eat, the part which pack ice cream is the edible crispy.This is a kind of very promising green packaging materials, is also very active in the field research.

Fig.1 Cotton fabric handbags

Fig.2 Ribbon embroider packing

Thirdly, we can develop in the direction of the using biodegradable packaging materials, biodegradable materials is a kind of plastic that its chemical structure will change in certain circumstances. The development of biodegradable plastic packaging materials, and gradually eliminate non-biodegradable plastic packaging materials is the trend of world science and technology development, and one of the hot spot of materials research and development. Biodegradable plastic packaging materials with both traditional plastic functions and features, and after it is used, through the microbial function of nature or the role of sunshine, it can be divided in the natural environment, and finally to return to nature in the form of non-toxic.

Beauty Of Simplicity On Design Idea

As a whole, the simplicity follow the "subtraction" principle, that minus unnecessary troubles in the largest extent, directly reveal the true nature of things, brief, simple, delicate, pure. "Subtraction" is a process that constantly changing and growing less and simple. "Subtraction" is a standard, a scale in the works of art appreciation and mastery of social life.

Design concept is to save material on the direction of development. In guarantee the basic function of packaging, we need reforming excessive packaging, developing moderate packaging, reducing the use of packaging materials, reducing the packaging cost, saving the packing material resources, reducing the discharge of waste packaging materials. One of the characteristics of this design is pursuitting concise simple materials and packaging frames.

For example, Japanese flavour essence company design of condiment packaging uses white sheet made of corrugated paper, and the label printing is plain.

Muji on the choice of materials pay attention to show the natural material itself unique aesthetic trait. Its products adhere to the principle of simple and durable, and pay attention to the efficiency of material, adopting the processing mode of concise, adhere to the simple packaging, and unified use without bleaching, environmental protection recycling recycled paper as product packaging under guarantee packing basic recognition and protection, abandoned the excess packaging. As advocate green design in the field of product design pioneer, Muji has practical success. As a goods, it abandoned the profiteering in multifarious packaging and precious raw material behavior. As shown in figure 2 ribbon embroider packing, Muji set his sights on reducing unnecessary costs, advocating rational consumption, pay attention to environmental protection and ecological balance, and this is the code of ethics should be follow by each developer, designer, manufacturer's.

Conclusion

A famous German designer had summed up the relationship between design and material, he put forward design directly associated with the new technology and new materials. While there is a new material, the old design will be reassessed. It is easy to find that the design thought is based on material, and the properties of materials is obtained by design. Every discovery, invention and application of a new material, all means that a new form of expression will be created and applied. Different material presents different features by reason of its material, craft. Therefore, in the process

of product design, material selection is extremely important, reasonable material application can not only enrich the content of the product and individual character, but also can make the product more produce new charm.

In a word, the age that only depend on own feelings of formal beauty design is over. Designers should keep up with the demand of times, cooperate with natural science, social science, and many other scientists, master the knowledge of advanced materials, create a better green design which meets the demands of the market, fully display the material itself value and aesthetic feeling and used it into product design, make the product reflect humane use value and aesthetic value. Let us hand in hand to create a new style, new material, "green life" design.

Keywords: Composite; Prepreg; Radius filler; Hand-made craft; Evaluative requirement

Abstract. Radius filler is a kind of filling material which is used in triangle gap of the composite girder and rib. To optimize the hand-made craft of radius fillers and specify the evaluative requirements for detecting radius fillers, a research on handcraft parameters of the radius fillers had been conducted; the boundary dimension, microstructure and mechanical property of the R6 radius fillers had been characterized with the use of different detective methods and the microanalysis includes: nondestructive testing; microscope photos; fiber volume fraction and void content. The evaluative requirements to detect the quality of radius fillers have been established and its validity has been confirmed by the R8 radius fillers.

Introduction

With the increasing development of composite, they are widely used for the components of large airplanes such as center wing box, vertical fin and so on with the combined structures of girder and rib with skin panels. [1, 2] Because composite is manufactured by attaching the mold, a large triangle gap will exist at the corner of girder and rib (as shown in the Fig. 1). Problems of crazing along the fibrous layer or destroying fibrous will emerge at the place where gap exists leading to the degradation of component performance under the effect of outside force, which is a big problem facing in engineering practice.

Aiming at the risk caused by this T type of structure, there are many kinds of solutions such as the curvature design of the corner, fixed by mental accessories, filled with resin or glue saluting and so on. With the development of technologies, the method is widely used to fill the gap at the corner of girder and rib with composite radius fillers.

Generally, The so-called composite radius fillers is to choose unidirectional or multi-directional composite pregreg which is made with certain technology applied into body structure in form of cylinder or triangular prism. Composite radius fillers can be put into the triangle gap of girder and bid play the role of filling and bonding after oven heating.

Currently, radius fillers are manufactured through manual operation in most places, but there will be some serious problems: it is hard to control the size of radius fillers for too big a size will cause the bulge while too small will cause the hollow on the surface of components; the performance of radius fillers is not stable so that the homogeneity of covering pregreg will make an influence on the formation of void and structural void and warp and damage of fibrous will weaken the force performance of filling materials; the product of radius fillers is not continuous so that only short radius fillers can be produced as a result that they must be used after jointing to fill large components; it takes a long time to produce radius fillers through manual operation. Meanwhile, there is no evaluation system to test and evaluate radius fillers, so it is very important for further engineering research and application to optimize the hand-made craft of radius fillers and standardize its evaluation system.

Boeing company made great efforts on the hand-made craft of radius fillers used for filling composite girder and rib. As early as the end of last century, Boeing put forward that producing unidirectional fiber reinforced composite laminate plates firstly and then cutting these plates into equilateral strips that are passed through rolling equipment to form radius fillers matched with the

gap in the patent of US4789594[3]. In the patent of US5650229[4], it proposed filling gap with radius fillers made up of unidirectional fiber adding stabilizer (consisting of bismaleimide resin, poly isocyanates and epoxy) at a proportion of 3-5% to get the shape needed to fill the gap and then infiltrating resin through RTM craft. By this mean, the fiber volume fraction can reach 60-70% to avoid transformation of resin-rich area and fiber efficiently. Next, in order to solve the problem of stress concentration in filling area, Boeing proposed the method of filling gap with radius fillers made up of titanium alloy in the patent of US5833786[5].

With the further research in 21st century, Boeing considered various elements including performance, weight and cost together as a whole and proposed a method of manufacturing composite laminate radius fillers in the patent of US6709538[6] that the gap was filled with multi-layer fabric with the layers of [0°/90°] or [±45°] and enough or excess resin. Compared with unidirectional or pure resin adhesive, laminate composite radius fillers can avoid the damage due to internal crack.

In the patent of US7758715[7], it put forward the method of taking thermoplastic material whose curing temperature was lower than that of composite components as radius fillers to fill the gap and taking good control of heating rate and time to get the radius fillers in good performance. Recently, Boeing proposed to produce radius fillers with nanostructure including carbon nanotubes, carbon nanofiber and carbon nanowires in patent of US20120074265[8] in order to strengthen the interface connection of filling materials with composite components. Meanwhile, viscosity of this composite can be controlled in terms of additive amount of nanostructure, radius filler appears to be semi-cured during the production process, and finally cured with other components.

To meet the demands of industrial production, Boeing designed a set of facilities used to produce radius fillers in the patent of US4559005[9] in 1985. However, this facility only can produce radius fillers with the same cross sectional dimensions and if the gap at the corner of girder and rib were changed, radius fillers will become too small or large and the groove of idler wheel needed to replace to change the size of radius fillers. Intelligent facility was created by Boeing in the patent of US4778545Z[10], This facility can measure the radius of circle, store and compute the sectional area of the gap and then cut the composite into strips as same the width as that of the gap and then make them into radius fillers.

In this investigation, technological parameters of hand-made radius fillers were studied and optimized, different detection methods were adopted to characterize the boundary dimensions, microstructure and mechanical properties. In terms of the characterized results chosen, this paper established initially a method of testing and evaluating the quality of radius fillers taking elements such as the cost and reliability into consideration, which paves the path for the engineering practice and further automatic production.

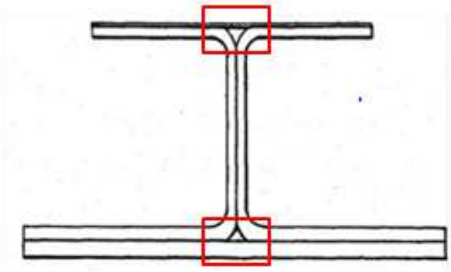

Fig. 1 Triangle gap of composite girder and rib

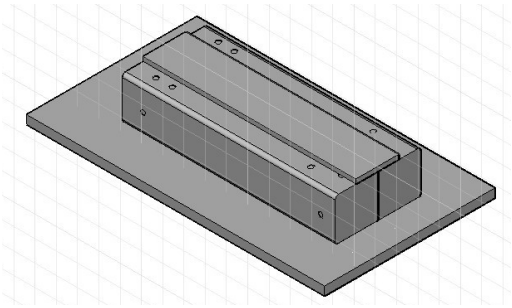

Fig. 2 Design of homemade mould

Experimental Investigation

Specimen fabrication. The material used for the specimen was T300-6k, unidirectional prepregs manufactured by the Jilin Petrochemical Company. This material has a fiber areal density of 150g/m^2, while the resin content is 33%.

A homemade mold which manufactured based on the investigation of the elevator is presented in Fig. 2. Each arris of the rectangle has a special radius of curvature, therefore, radius fillers with the size of R2,R4,R6,R8 can be respectively prepared used the mold.

Theoretical relationships between the Prepreg add volume and the size of radius filler are described in Eq. 1.

$$\frac{A\times(1-R)\times \mathrm{b}}{\rho} = S\times V_f \quad (1)$$

Where A and R is the prepreg areal density and resin content, b is breadth of the additive amount of the radius filler, ρ and V_f is the fiber density and volume fraction. The theoretical sectional area of the cavity, S, can be expressed as a function of the radius of radius filler curvature r:

$$s = 0.43r^2 \quad . \quad (2)$$

However, hollow defects appeared in the Specimen when we applied the dosage calculated by the Eq. 1.So an authentication method had been applied to amend Eq. 1. The cavity filled with gypsum was used to simulate the shape of the mold cavity. Five simulated simple with better section was polished with 180 # sandpaper, and then record the gypsum section with red ink pad. Cross-sectional area and other parameters was measured and calculated with a Ruler. The self-designed R6 cavity average cross-sectional area is 21.1mm^2 that can be obtained from the data in Table 1.

Table 1 Area parameters of mold cavity

Number	Left R [mm]	Right R [mm]	Area of calculation [mm^2]	Area of measurement [mm$^{2]}$	Area of overflowing [mm^2]
1	6.5	6.6	20.4	23	11
2	6.5	6.5	20.2	30	11
3	6.8	6.8	22.6	28	11
Average	6.6	6.6	21.1	27	11

A new equation, Eq. 3, had been put forward. Where S' is the measured sectional area of the cavity, L' is the area of the overflow part.

$$\frac{A\times(1-R)\times b}{\rho} = (\mathrm{S'+L'})\,\mathrm{V}_f \quad (3)$$

Given the fiber volume fraction which you need, the additive amount of the radius filler prepreg can be calculated.

A range of additive amount of the radius filler prepreg had been designed (as shown in table 2) for the investigation refers to Eq. 3. Prepreg was wound into a compact cylindrical, then put into the cavity of the mold. No.1-12 semi-cured and cured 24 radius fillers were made up by the craft of the Vacuum Assisted Resin Infusion (VARI) which is described in Fig. 3.The semi-cured process was 60℃ for 30 minutes, while the cured process was 80℃ for 45 minutes, then 120℃ for 75 minutes.

The quality characterization of the radius filler. Ultrasonic C-scan NDT was applied to characterize the semi-cured radius fillers in the research. The cured radius fillers had been characterized from three aspects: boundary dimension; microstructure; mechanical property. While, microstructure which also includes: non-destructive testing, metallurgical analysis, fiber volume fraction and porosity.

The floating of the radius filler boundary dimension was not so obvious since it was cured in the rigid mold. Five groups of width and thickness (Fig. 4) from appropriate intervals (2mm-3mm) were measured by the caliper, then their average values were calculated.

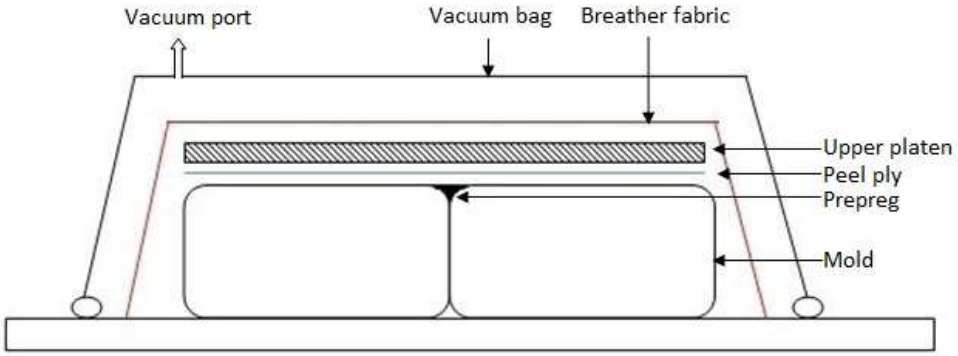

Fig. 3 Schematic diagram of the radius filler craft

Table 2 Additive amount of the radius filler prepreg

Specimen	Breadth [mm]	Specimen	Breadth [mm]	Specimen	Breadth [mm]	Specimen	Breadth [mm]
1	158	4	176	7	194	10	220
2	164	5	182	8	200	11	230
3	170	6	188	9	207	12	240

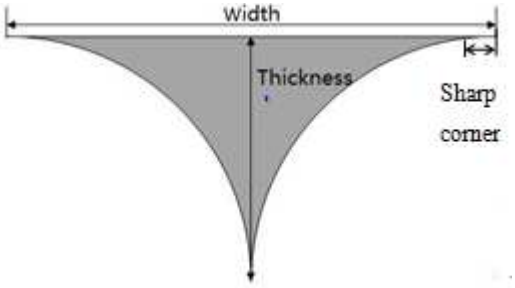

Fig. 4 Size sketch of the radius filler

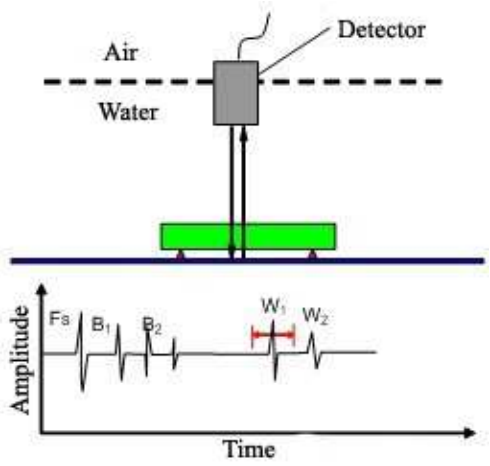

Fig. 5 Propagation path of the ultrasonic wave

Water Immersion Ultrasonic C-scan NDT was used to detect the radius fillers. C-scan images were obtained by utilizing the reflector to detect echo information. Acoustic propagation is described in Fig. 5.

Where F_S is specimen surface echo; B1 and B2 are specimen bottom echo and secondary echo; W1 and W2 are reflector surface echo and bottom echo at the bottom of the container.

Microscope photos of the cured specimens were obtained from two random cross-sections.

Fiber volume fraction and void content of the cured specimens were calculated by using the microscope photos and Sisc IAS refer to standard GB/T 3365-2008.

INSTRON 5982 mechanical testing machine was used for the bending performance test of the cured specimens refer to the standard GB/T 1449-2005. The testing results will be used to detect whether the cured specimens meet the design requirements.

Results and discussion. The added amount of the prepreg will have a greater impact on the curing size. Radius filler will not be closely connected with the product owing to its small size when the added amount of the prepreg is not sufficient. And other defects, e.g. great stratification, hollow filler will appear. However, embossment in the triangular area can be found when the added amount is over sufficient.

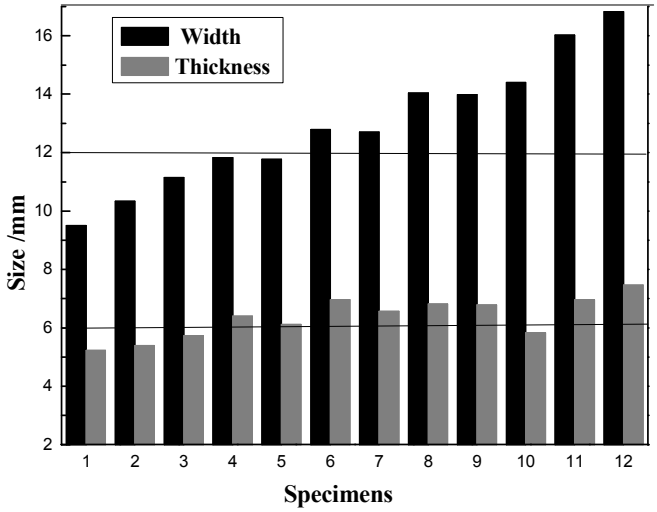

Fig. 6 Size contrast of the cured radius filler

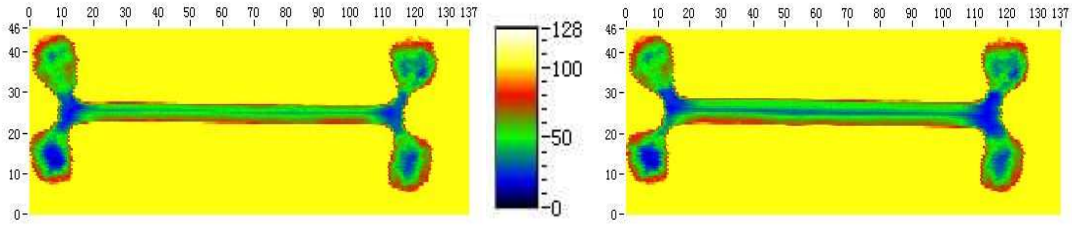
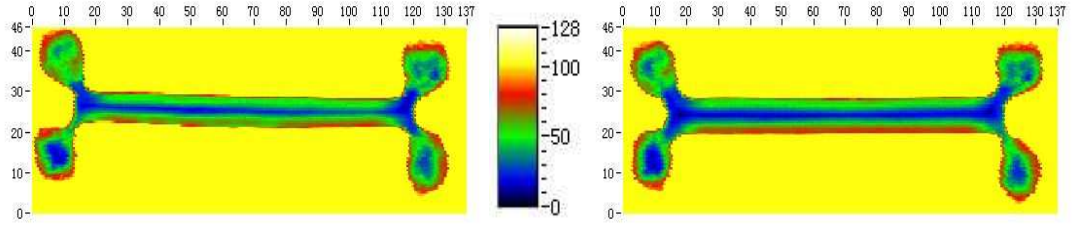
The relationships between the size of the radius filler and the added amount of the prepreg are presented in Fig. 6.As observed in this figure, the width and thickness all rise with the added amount. The size of the radius filler needs to be controlled in a certain range when it is used as filler in the interspace of the stiffened panel structure. Compared to the desired size (width of 12mm, thickness of 6mm), size error of the specimens No.5,6,7,8 are in the range of 15% . And start from No. 6, the size of the specimens is larger than the desired size.



Water Immersion Ultrasonic C-scan NDT was used to detect both the semi-cured and cured radius fillers, at the same time, representative specimens were selected. Test results are presented in Fig. 7 and Fig. 8.

As an uneven thickness and complex part, uniformity of the ultrasound spectrogram color change reflects the uniformity of the fiber arrangement in the radius filler. Theoretically, the thicker and the more compacting of the specimen, the more attenuation of ultrasonic signal, then the darker the spectrogram will be. On the contrary, the shallower the spectrogram will be.



Spectrogram of the semi-cured specimen No. 1 (Fig. 7(a)) is mainly green, a thin blue line appears in the middle, and the edge is faint red. The dark range increases in the spectrogram of the semi-cured specimen No. 5(Fig. 7(b)), however, there are some ups and downs at the interface over blue and green. Therefore, specimen No.5 is poor uniformity, thickness and compaction. The dark range continue to increase in the spectrogram of the semi-cured specimen No. 7(Fig. 7(c)), the interface still be some ups and downs. Then the thickness and density of the No.7 is better, and its uniformity has improved but still is not so good.

The color distribution of the ultrasound spectrogram is related to the shape of the radius filler. As a typical prism, its ultrasound spectrogram turns to shallow from the middle to the edge owing to its different acoustic attenuation. Color difference of different specimens illustrates the difference of their density and uniformity. As observed in Fig. 7, the density of the semi-cured specimens rises with the additive amount of the prepreg at the same pressure. Thickness and density of the specimens are overall good start from the specimen No.7.

The NDT results of the cured specimens are presented in Fig. 8. Large areas with good thickness and density appear from the specimen No.6, in which, more echo attenuation occurs in most areas of the cured specimen No.8, corresponds to the blue area of the Fig. 8 (d), and the degree of attenuation is approximately 80%.Variation of the cured specimens spectrograms is similar to the semi-cured specimens, namely, the density of the cured specimens rises with the additive amount of the prepreg at the same pressure. At the same time, the interface over the different color on the image appears to be a straight line, therefore, the uniformity of the cured specimens dimension and internal structure is better than the semi-cured.

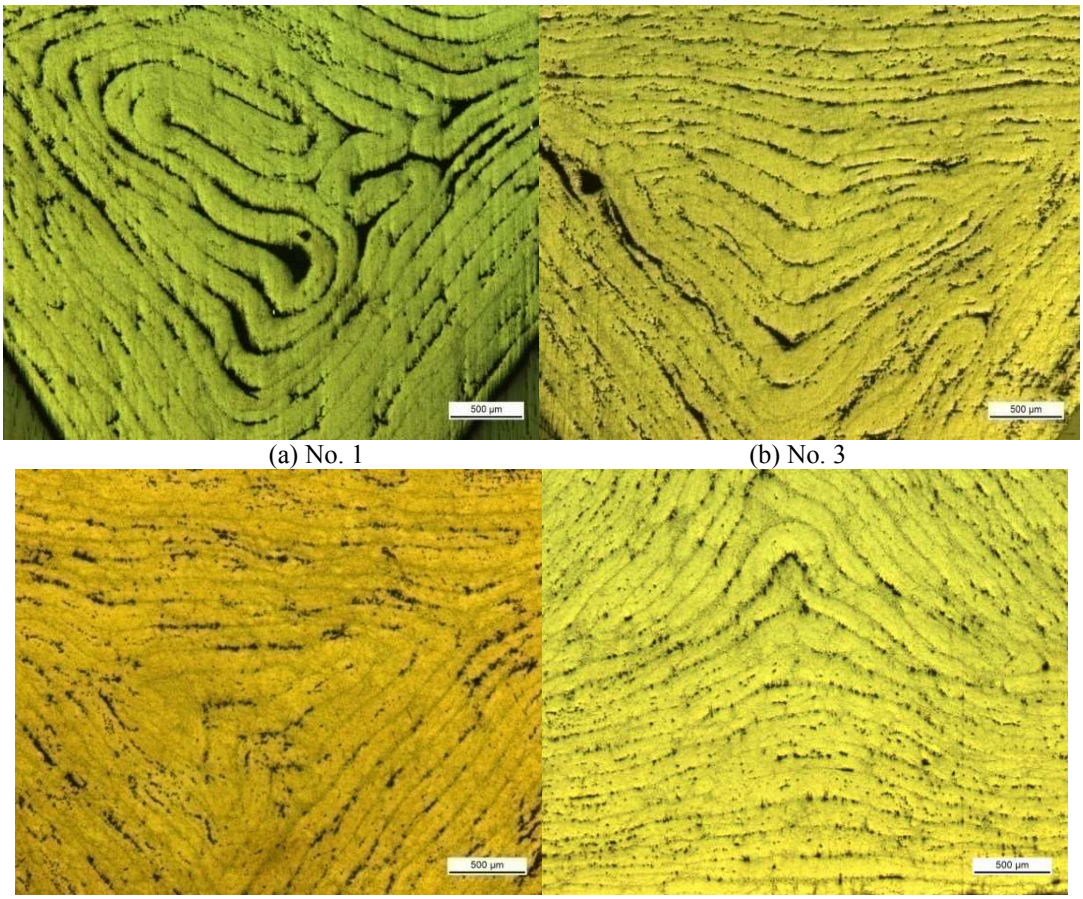
Fig. 7 Nondestructive testing (NDT) spectrograms of the semi-cured specimens

(a) No. 1 (b) No. 3



(c) No. 6 (d) No. 8

Fig. 8 NDT spectrograms of the cured specimens

Representative microscope photos of the cured specimens are given in Fig. 9. Internal structure of the specimen No.1 (Fig. 9 (a)) is incompact, numerous voids concentrated in the interlayer, large voids distribute in the core of the triangle, and fibrous layer appears to be disorganized. Void size of the specimen No.3 is smaller than the No.1 as a result of the increase additive amount of the prepreg. Although the core of the triangle is filled with fibers, lots of medium-sized and little large-sized voids still exist, gaps in the interlayer are still obvious. As seen in Fig. 9 (c), gaps and large-sized voids of specimen No.7 have disappeared, Most of the areas get a better density in case of the decrease of the voids. Fiber layer of specimen No.11 arranged neatly, the density has been great improved, the voids appear to be small and uniformly distributed.

As depicted in Fig. 9, all defects occur in the interlayer, moreover, probability and size of the interlayer defects reduce with the increase of the additive amount of the prepreg. However, the defects are inevitable even if the additive amount of the prepreg is sufficient, and it can be explained by four reasons [11]: (1) cavitation and folds produced by hand-folding; (2) blocking of the stomatal channel during pre-compaction; (3) volatilizing of the small molecule volatile components in the resin; (4) bubbles left caused by the bending, deformation and fracture of the fibers. Therefore, defect rate should be controlled within the acceptable range during the actual production process.

(a) No. 1 (b) No. 3

(c) No. 7 (d) No. 11

Fig. 9.Microscope photos of the cured specimens

Fiber volume fraction is around 60% begins with specimen No.6, and increased to about 62% start from the specimen No.8, as seen in Fig. 10. Owing to the requirement of 62% of the fiber volume fraction with autoclave molding in the aerospace field, 60% of the fiber volume fraction as dividing line using VARI craft (a standard atmospheric pressure conditions) is selected in the research to guarantee that the quality of the radius fillers meets the requirements of aerospace in the autoclave conditions. As observed in this figure, fiber volume fraction rises with the increase of the additive amount of the prepreg. Fiber volume fraction of most specimens is more than 60% and meets the design requirements start from the specimen No.6.

The void content of the specimens is large at the beginning, it can be controlled within 3% start from specimen No.7, and it reduced to 1.51% ultimately (specimen No.12) in the case of the increase of the additive amount of the prepreg, shown in Fig. 10. Therefore, the void content decreases with the increase of the additive amount.

Maximum bending load of the cured radius filler linear increases with the increase of the additive amount of the prepreg within the permitted error range, as illustrated in Fig. 11. Moreover, maximum bending load is 1200N, the corresponding additive breadth of the prepreg is 190mm which between the specimen No.6 and No.7 when plotting on the linear fitting curve of Fig. 11. The overall performance of the specimens can meet the design requirements start from the No.6, therefore, maximum bending load of 1200N can be seen as an evaluation requirements of the radius filler mechanical properties.

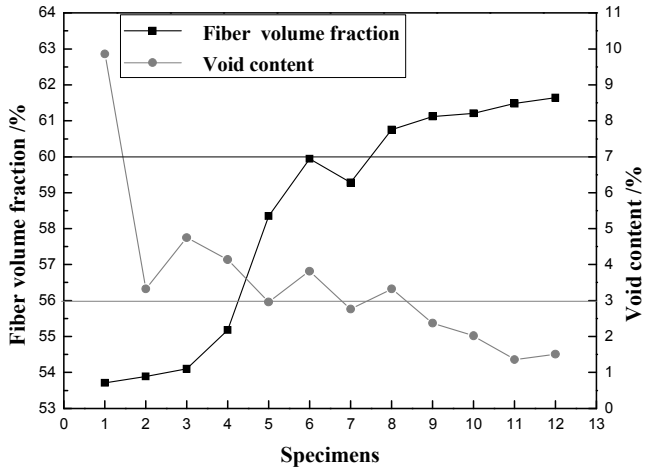


Fig. 10 Fiber volume fraction and void content of the cured specimens

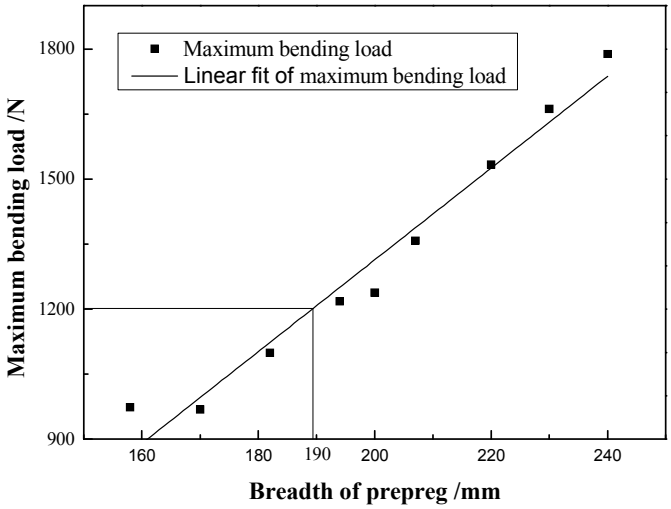

Fig. 11 Bending test results of the specimens

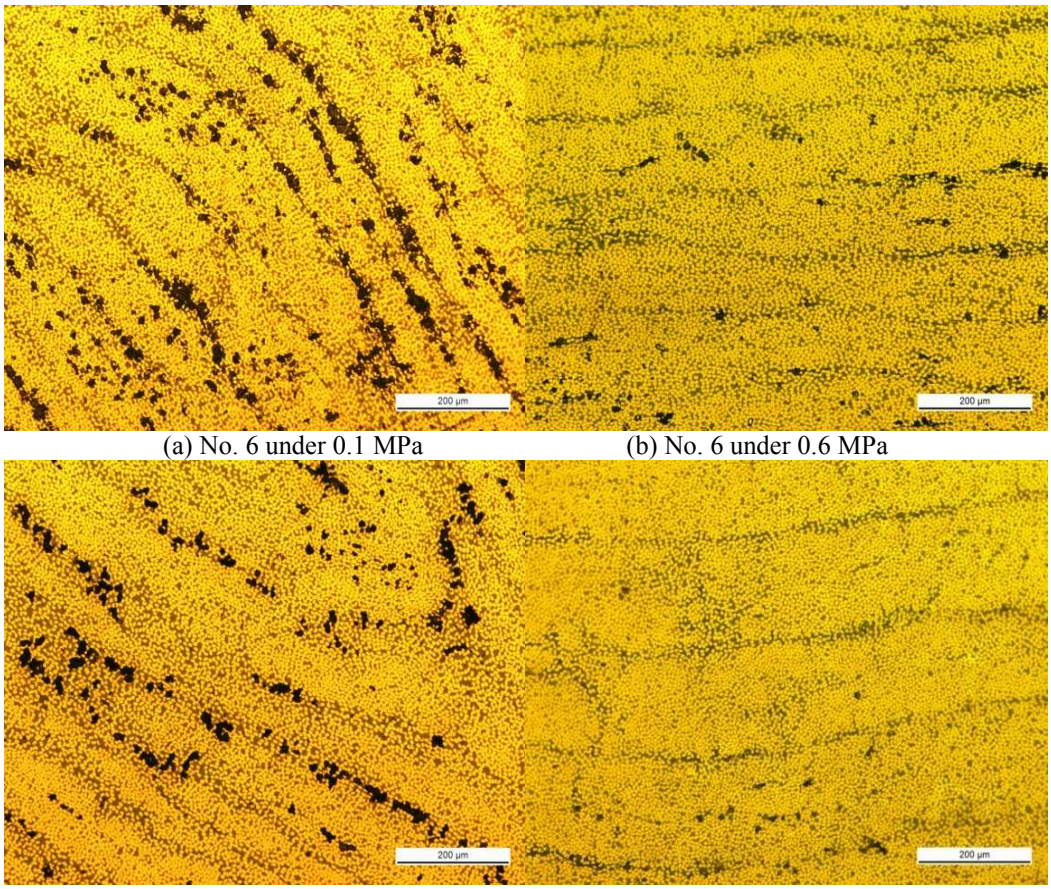

Table 3 Contrast of the radius filler under different pressure

Specimen	Pressure [MPa]	Width [mm]	Thickness [mm]	Void content [%]	V_f [%]
6	0.1	12.79	6.96	3.82	59.94
	0.6	11.90	6.13	2.38	60.27
7	0.1	12.71	6.57	2.76	59.28
	0.6	14.26	6.96	2.12	61.44

In summary, width and thickness of the radius filler increase, internal uniformity, density and fiber volume fraction rise, void content decrease, maximum bending load almost linear increase with the increase of the additive amount of the prepreg.

In order to compare with the cured specimen formed under 0.1MPa pressure, hot compacting was selected to simulate the actual pressing process of the specimen, and its performance was tested for the fact that curing pressure is 0.6MPa in practical aerospace applications. Specimen No.6 and No.7 which are the most representative specimens were chosen to show the differences.

Void content of the two hot compacted specimens is about 2% which has a large degree of decrease, as described in Table 3. The residual air and other volatile components in the interlayer have been dissolved in the resin due to the great pressure [12], therefore, the internal structure of the radius fillers becomes more dense and uniform, there was greater improvement of the fiber volume fraction, and the void content of the specimens appears to be decrease (Fig. 12).

(a) No. 6 under 0.1 MPa (b) No. 6 under 0.6 MPa

(c) No. 7 under 0.1 MPa (d) No. 7 under 0.6 MPa

Fig. 12 Microscope photos of the No. 6 and No. 7 cured specimens under different pressure

Establishment and verification of radius fillers' evaluative requirements. A series of quality evaluative requirements have been established based on the characterization and analysis of the R6 radius fillers. The using state of radius filler is prepreg, it is usually filled in the interstice and cured under the pressure of 0.6 MPa. The size, void content, fiber volume fraction of the radius filler change with the increase of the pressure, therefore, the Dimensions of the hand-made radius filler, semi-cured and cured specimens should meet the following requirements:

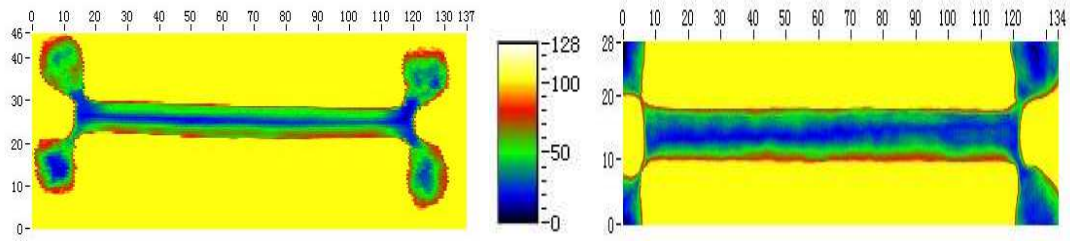
(1) Dimensions

The width and thickness error of the prepreg should be controlled in the range of +15% compared to the theoretical size.

(2) Microstructure

a. Standard NDT spectrogram of the semi-cured radius fillers is shown in Fig. 13 (a).

b. Standard NDT spectrogram of the cured radius fillers is shown in Fig. 13 (b).



c. Standard microscope photo of the cured radius filler is shown in Fig. 13 (c).

d. Void content of the cured radius filler should be controlled less than 3%.

e. Fiber volume fraction of the cured radius filler should be controlled more than 60%.

(3) Mechanical property

Maximum bending load of the cured radius filler obtained by the three-point bending test should be larger than 1200N.

(a) Semi-cured radius filler (b) Cured radius filler

Fig. 13 Standard NDT spectrogram of the radius fillers

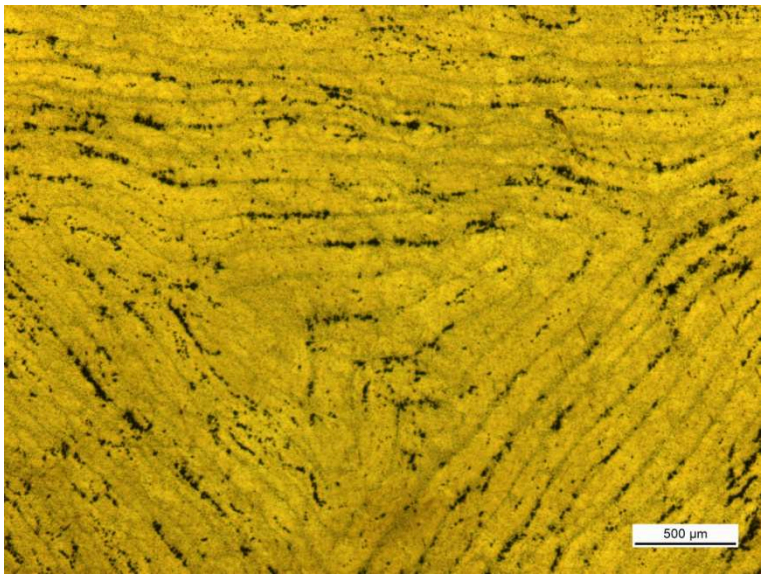


Fig. 14 Standard microscope photo of the cured radius filler

R8 radius filler was selected to verify the validity of the evaluative requirements. The theoretical additive breadth of the radius filler is 300mm calculated by Eq.3. Therefore, two additive amounts are designed, one is 300mm, the other one is 310mm, and the process is the same with R6 radius filler.

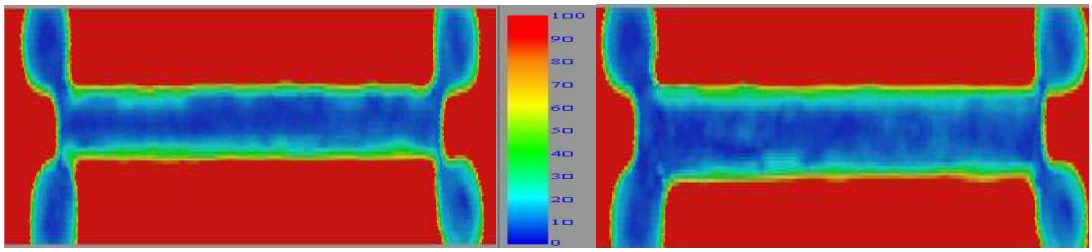

Table 4 Relevant data of the radius filler

Specimen	Width [mm]	Thickness [mm]	Void content [%]	V_f [%]	Maximum bending load [N]
a	16.52	7.90	0.63	58.31	1221.37
b	16.67	7.98	1.47	61.81	1522.58

As described in Table 4, the actual width of the cured specimen (a) is 103.3% of the theoretical width, the actual thickness of it is 98.8% of the theoretical thickness. While the actual width of the cured specimen (b) is 104.2% of the theoretical width, the actual thickness of it is 99.8% of the theoretical thickness. And both of their void contents are less than 3%, their fiber volume fraction is 58.31% and 61.81%, which is very close to or more than 60%. Meanwhile, maximum bending load of the cured radius filler (a) and (b) is larger than 1200N.

Nondestructive testing (NDT) spectrograms of the R8 cured radius fillers are presented in Fig. 15. As observed in this figure, structural uniformity, thickness and density of the R8 specimens have met the evaluative requirements. Small-sized voids with uniform distribution appear in the interlayer, rather than medium-sized and large-sized voids, as shown in Fig. 16.

Therefore, all aspects of the R8 radius fillers can meet the evaluative requirements, and the validity of the evaluative requirements has been verified. The evaluative requirements can be popularized to the hand making of other radius fillers.

(a) (b)

Fig. 15 NDT spectrograms of the R8 specimens

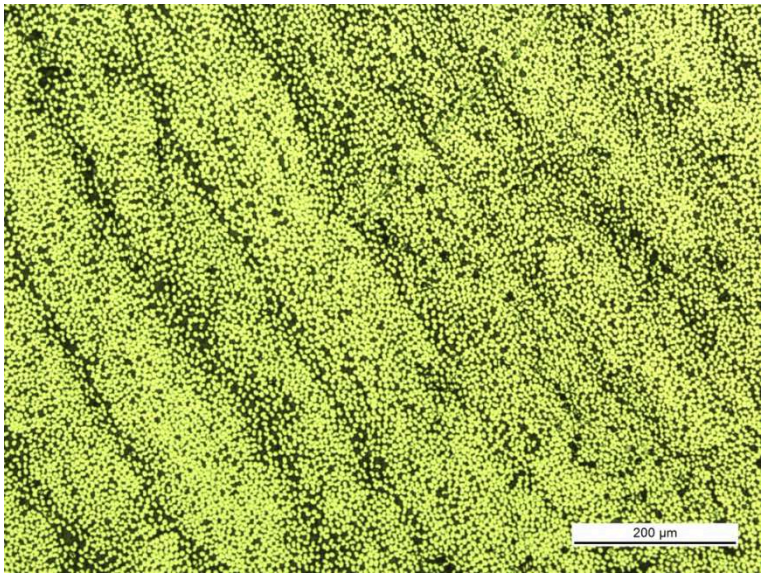

Fig. 16 Microscope photos of the R8 cured specimens

Conclusions

A kind of commonly commercial used prepreg was selected, and a series of hand-made radius fillers had been characterized and evaluated in this study. The achievements can be summarized as follows:

(1) The R6 radius fillers had been manufactured and been characterized from three aspects: boundary dimension; microstructure; mechanical property. While, microstructure which also includes: non-destructive testing, metallurgical analysis, fiber volume fraction and porosity.

(2) A set of systematic quality evaluative requirements had been established by the characterization and analysis of the R6 radius fillers.

(3) R8 radius fillers which meet the dimension requirements had been made owing to the accurate calculation of the additive amount of the prepreg by Eq.3. Meanwhile, the validity of the evaluative requirements had been verified by the analysis of its microstructure and mechanical property.

It is significant to establish a set of systematic evaluative requirements for the quality evaluation of the manual and the future automated radius fillers. Automated production will become the mainstream in the production technology of the radius fillers due to the significant limitations of the hand-made craft. Exploration on the automated production of the radius fillers will be the forthcoming work in our laboratory.

Comparative Study Of High-Power White Led'S Lifetime Based On Temperature Accelerated Test

Shi wei, Zou Nianyu, Zhang Yuncui, Li Desheng

Research Institute of Photonics Dalian Polytechnic University

No.1 Qinggongyuan, GanjingziDist, Dalian 116034, China

email: desheng@dlpu.edu.cn

Keywords: LED; lifetime; temperature; Arrhenius model.

Abstract: The lifetimes of two white high-power LEDs were studied based temperature-acceleration life test. the acceleration temperatures were selected as 100°C and 90°C separately in the experiment, and the accelerated time was 800 hours. Based on Arrhenius model, activation energy of the two tested samples are 0.6978 and 0.7014 separately, and lifetime are7.41×10^5h and 1.46×10^5h separately. Our experimental results showed that the quality of the two type LEDs is very different, and lifetime of 50000 hours is recommended as the threshold of entering the market for high power white LEDs.

Introduction

The white LED is considered as one of the most potential and preponderant commodities, which can replace traditional lighting device in the industry. White LEDs gradually enter the field of general lighting with lower cost and the increase of luminous efficiency [1]. But at the moment, the quality of white LEDs is very differently. Take lifetime for example, the lifetime of good quality LEDs can reach tens of thousands of hours, but some products can only own a few thousands hours. Long lifetime ensures LED can be widely used in various areas, so the study on the reliability of LED is very important [2-6].

Recently, there are two main approaches to test high-power LED's lifetime, which are temperature acceleration experiment and current acceleration experiment [7-8].The main mechanism of Accelerated lifetime test (ALT) is to make devices work in higher stress than the actual stress levels, so as to shorten the failure time of the device, and then according to the calculation formula to get the lifetime under normal use conditions. In this paper, the lifetimes of two white high-power LEDs were studied based temperature-accelerate life test, and some recommendations for evaluating white LED's lifetime and establishing related standards were proposed.

Arrhenius model

Arrhenius model is commonly utilized in temperature-accelerated lifetime test, which reflects the connection among product's performance, activation and stress. The luminous power of LED is degenerative with time, and the relationship is expressed in the form of exponent, as following,

$$P_t = P_0 exp(-\beta t) \quad (1)$$

Where, P_t is luminous power (or flux) after time t, P_0 is original value of light efficacy (or flux), β is the attenuation coefficient under certain temperature.

The lifetime of LED is usually defined the time of flux from original to 70%. In accelerated lifetime test, for luminous power attenuate to P_i after t_i , the relationship between them is given by equation (2).

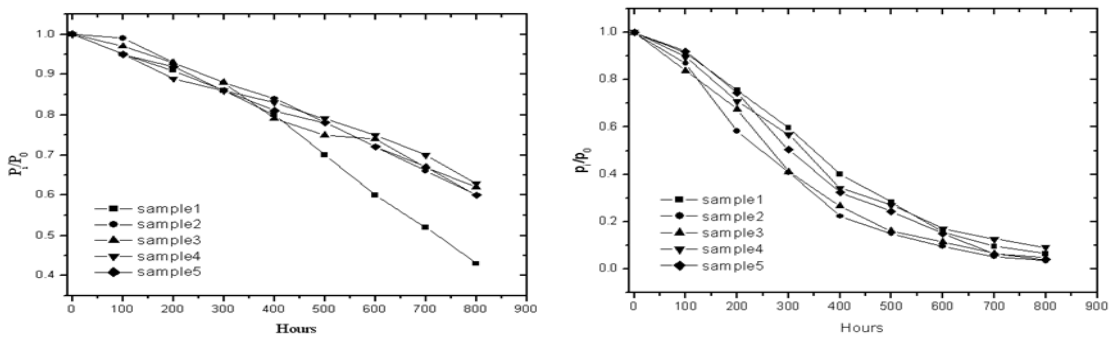
$$L_{(c,i)} = t_i \frac{ln0.7}{ln\frac{P_i}{P_0}} \tag{2}$$

Where, $L_{(c,\,i)}$ is the time of flux from original to 70%.

The attenuation coefficient and junction temperature T_j satisfy Arrhenius model, as showed in equation (3).

$$\beta = \beta_0 I_f \exp(-E_a/kT_j) \tag{3}$$

Where, I_f is operating current of LED, and E_a is activation energy, which is one certain value for certain LED. Combining equation (1) and (3), the lifetime of LED L_c in normal condition could be calculated.

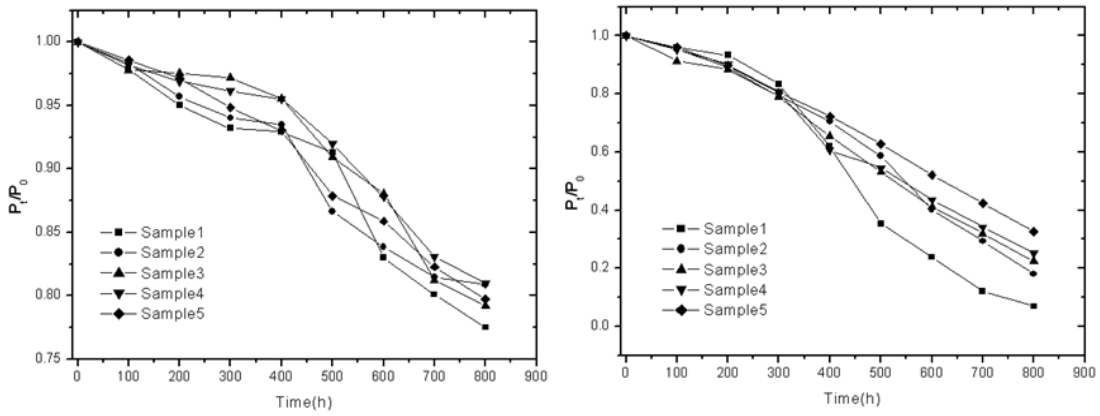


$$L_c = L_{(c,i)} \exp \frac{E_a}{k} \left(\frac{1}{T_{(j,o)}} - \frac{1}{T_{(j,i)}}\right) \tag{4}$$

Where, $T_{(j,i)}$ is the junction temperature of LED under accelerated temperature, $T_{(j,o)}$is the junction temperature of LED under normal operating conditions.

Experiment and result analysis

The tested white LEDs are selected from different manufacturer production, Marked as sample A and sample B, respectively, and ten LEDs were selected randomly for each kind of sample. In the experiment, all the tested LEDs were stressed under two different forward-temperature densities 100°C and 90°C for up to 800 h. The temperature stress is provided by high and low temperature alternating temperature humidity test chamber, which is applicable for the testing of electrical and electronic products, components and parts in high-temperature, low-temperature, humid and heat environment. The samples were tested at intervals of 100 hours at ambient temperature, using an integrating sphere and a silicon photodiode-array fiber-optic spectrometer. To ensure accurate measurements of the changes in light output, the testing setup remained constant during the stress period.



The luminous flux degradation curve for two kind of tested sample sunder 100°C and 90°C were obtained, shown in Figure 1 and Figure 2, respectively.

sample A sample B

Fig.1. Luminous flux curves of tested samples under 100°C

Under the condition of 90°C, Two samples of luminous flux decay curve is shown in figure 2, respectively.

sample A sample B

Fig.2. Luminous flux curves of tested samples under 90°C

The thermal resistances of two kinds of LED samples are about 9°C/W and 15°C/W. Assume using under ideal conditions, that is, the shell temperature is 25°C, thermal resistance temperature of two samples are 9°C and 15°C, respectively. Based on the theory of Arrhenius model, the activation energy of sample A is 0.6978 and sample B is 0.7014. Lifetimes of the two kind of tested LEDs were calculated. And our experimental results showed that the lifetime of the two type LEDs is very different, 7.41×10^5h and 1.46×10^5h separately, which means the quality of sample A is much better than sample B.

Conclusion

The actual lifetime of white LED has become the major concern, whether for LED light source manufacturers or LED light source users, so it is very important to study the lifetime of white LED. In this article, Comparative study of high-power white LED's Lifetime through temperature accelerated test based on the Arrhenius model were demonstrated, and lifetime of two type of tested samples are calculated 7.41×10^5h and 1.46×10^5h respectively. Nowadays, both high quality white LEDs and low quality products are exist on the market, so it is very important to establish relative national standard to constrain the quality of LED products. Here lifetimes of 50000 hours were suggested for high-power white LED as the threshold of entering the market.

Keywords: surface-enhanced Raman scattering; crystal violet; silver colloid; acid effect

Abstract: We reported the spectra intensity of surface enhanced Raman scattering (SERS) for crystal violet with changing the acid concentration. The SERS signals of crystal violet ascended firstly and then descended with the acid concentration increasing when we put the nitric acid into the crystal violet-silver colloid system. The phenomenon was considered to be associated with the interaction between hydrogen ions and crystal violet, which may influenced the SERS signals.

Introduction

Surface-enhanced Raman scattering (SERS) is a unique surface optical phenomenon for that Raman signals of the molecules adsorbed on some metal surface can be enhanced by a factor of several millions. Surface-enhanced Raman spectroscopy shows high sensitivity for detecting the molecules in sub- and monomolecular layers, and presents plentiful surface informations of the structural change. Therefore, the spectroscopy has been widely used in some scientific and technical fields, such as chemistry, biology, surface science, qualitative and quantitative analysis [1-10]. SERS has become a usefule techinique for the rising monomolicular science [8]. The appropriate substrate is the premises to obtain favorable surface enhancement and metal colloids are widely used as substrates for their low cost, simple preparation and favorable enhancement [4, 5].

Crystal Violet (CV) is a purple dye molecule and also a kind of biological chromosin due to the strong fluorescence [11-15]. CV molecules have the characteristics of typical symmetric structure, belonging to three aryl dye and three dimethyl aniline groups link in the center of carbon atoms. CV molecules can interact with biological macromolecule, such as DNA and protein, so that the signals of CV via spectrophotometric or light scattering methods can be measured to indicate the structural changes of DNA or protein. CV could be used as Raman markers and the structure information of molecules marked by CV molecules could be detected via Raman microscopy. However, there is little work on SERS spectra of CV at different solution acidities. In this manuscript, we study the SERS signals of CV with changing the solution acidity and explain the possible mechanisms.

Materials and Experiments

Reagents: Nitric acid (HNO_3); Sodium citrate ($Na_3C_6H_5O_7 \cdot 2H_2O$); Silver nitrate ($AgNO_3$); CV ($C_{25}H_{30}N_3Cl \cdot 9H_2O$). The reagents were analytically pure and the water was three times distilled deionized water.

Silver colloid was prepared according to Lee's method [1]. 36mg silver nitrate was added into 200 ml deionized water and heated to boilling rapidly. Then, 8 ml sodium citrate solution with a concentration of 1% was added with vigorous stirring. Boiling state was kept for 60 minutes and naturally cooled to room temperature with stable stirring. The dark gray green silver colloid was prepared to be added to CV solution as the suface-enhanced substrate for detection of SERS spectra.

Raman spectra was acquired by a confocal micro-Raman spectrometer (Jobin-Yvon, T64000) equipped with a 514.5 nm diode laser and an integrated Olympus IX81 microscope.

Results and Discussions

Figure 1 shows the typical Raman spectra of CV after incubation with the silver colloids (b) and the normal Raman spectra (a). The SERS spectra show a high signal-to-noise ratio whereas the normal spectra are not oberved at the same experimental conditions.

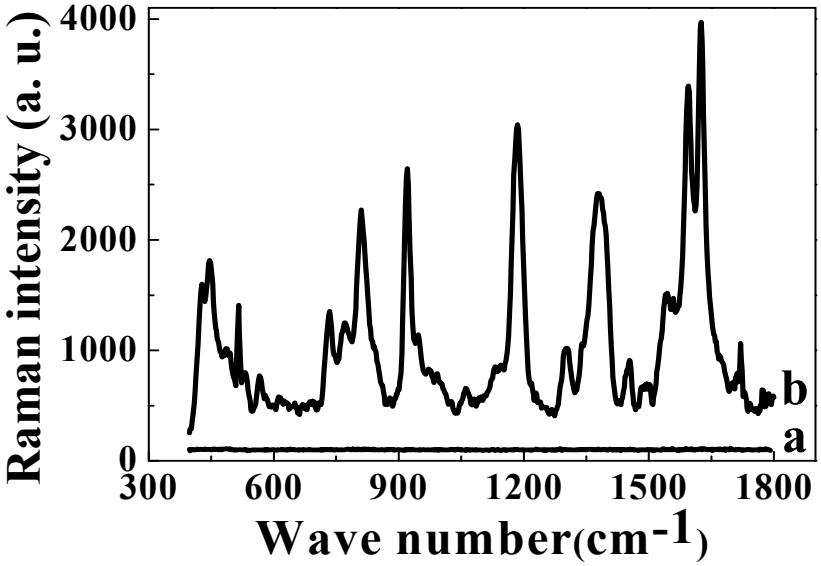

Fig. 1 Raman spectra of CV solution (1×10^{-6} mol/L)：a normal Raman spectra；b SERS spectra.

Most of the Raman bands are observed for the SERS spectra, which indicates the good adsorption between CV molecules and silver nanoparticles. After adding the silver nanoparticles, the fluorescence quenching of dye molecule, change of system colors and increase of resonant scattering may be due to the micelles formation and molecular polarization effects [14]. Nitrogen atoms in CV molecules have lone pair electrons and the benzene ring has π electrons, which results in the charge transfer between the CV molecules and the silver atoms surface as well as a molecular channel of nonradiative attenuation. The fluorescence of CV molecules quenches greatly and the enhanced Raman signals are obtained.

Nitric acid with a concertration of 5×10^{-3} mol/L is added into CV-silver colloid system and the intensity of SERS spectra increase 5-10 times, as shown in Fig. 2.

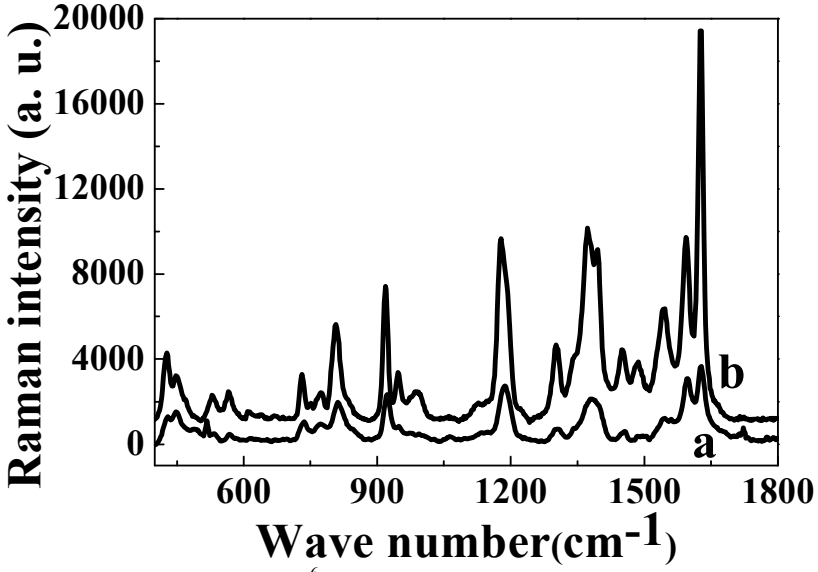

Fig. 2 SERS spectra of CV (1×10^{-6} mol/L) without nitric acid (a) and with nitric acid (b).

The SERS spectra bands corresponding to the information of the molecular structures are shown in Table 1 [14].

Table 1 Assignment of SERS bands for CV with and without nitric acid

SERS bands [cm^{-1}]	SERS bands after nitric acid addition [cm^{-1}]	Assignment of vibration modes
427.8	427.1	Out-plane vibration of Ph-C^{+}-Ph bend
531.8, 567.2, 920.7, 946.7, 1015.3	528.9, 565.6, 609.0, 918.1, 946.7, 988.3, 1016.7	Ring skeletal vibration of radical orientation
734.1, 770.0, 810.0	731.3, 773.9, 807.4	Out-plane vibration of ring C-H bend
1185.0	1178.4	In-plane vibration of ring C-H bend
1303.6	1301.4	Phenyl ring C-C stretching
1379.0	1372.7, 1395.7	N-phenyl stretching
1449.6, 1493.0	1449.6, 1486.8	Phenyl ring C-C stretching + ring deformation
1546.3	1546.3	Phenyl ring C-C stretching + N^{+} = phenyl stretching
1595.2	1593.3	Phenyl ring C-C stretching and bend
1623.6	1625.8	Phenyl ring C-C stretching + N - phenyl stretching

According to the SERS bands of CV in Table 1, when CV molecules are adsorbed on silver colloid surface and mixed with acid solution, most of the bands are enhanced and frequency-shifted, from which the interaction between CV molecules and silver nanoparticles can be infered. Bands at 916.3, 947.6, 527.2 and 566.2 cm^{-1} are assigned to ring skeletal vibration of radical orientation and relative intensity has a large increase in SERS spectra, which indicates that the CV molecules are adsorbed on the surface of silver colloid via a big π bond. Therefore, intense interaction of the nitrogen atoms and carbon atoms with silver ones is produced, which analogously acts as an coordination bond. With regard to the 5-10 times increase of SERS spectra intensity of CV after nitric acid addition, we propose that the combination of hydrogen ions with CV molecules may generate a kind of unstable coordination compond only existing in the acidic condition, which is electropositive and more easily adsorbed on the silver colloid so that better Raman signals are obtained.

We add the nitric acid of different concentrations into CV-silver collide system and measure the respective SERS spectra, as shown in Fig. 3.

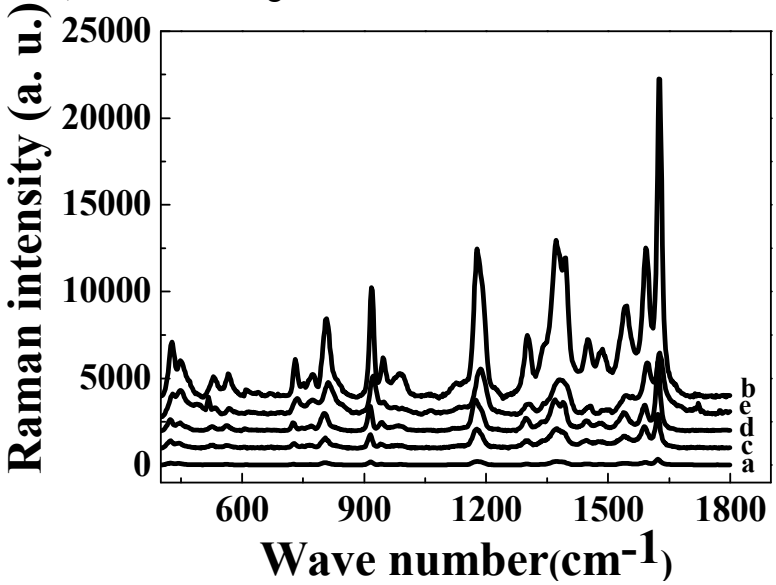

Fig. 3 SERS spectra of CV-silver colloid in nitric acid solution at different concentrations. a 0mol/L; b 0.005mol/L; c 0.0001 mol/L; d 0.01 mol/L; e 0.001mol/L.

Six characteristic SERS bands of CV are chosen to be compared dependent on the concentrations of nitric acid solution, given in Fig. 4. The intensity of SERS bands at 427.1, 918.1, 1176.2, 1301.4, 1593.3, 1625.8 cm^{-1} ascends gradually with the acid concentrations increasing from 0 to 0.005 mol/L and descends with the acid concentrations further increasing, which indicates a maximum value of SERS spectra intensity for CV with the modification of acid concentrations.

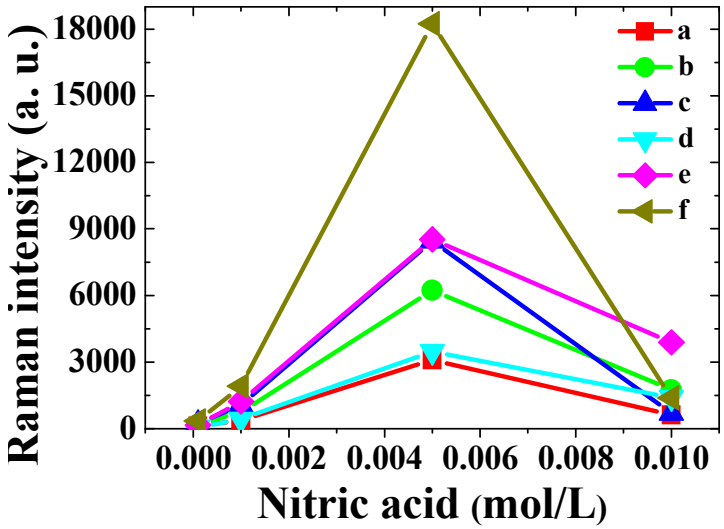

Fig. 4 The intensity of six characteristic SERS bands as a function of concentrations of nitric acid solution. Bands [cm-1]: a 427.1; b 918.1; c 1176.2; d 1301.4; e 1593.3; f 1625.8.

A kind of unstable coordination compond, only existing in the acidic condition, is produced by combination of hydrogen ions of nitrid acid with CV molecules, while it is electropositive and more easily adsorbed on the silver colloid, which leads to better Raman signals. The quantities of the coordination compond increase following the concentration of hydrogen ions (namely acid concentration), so the SERS signals asend in the acid concentration range from 0 to 0.005 mol/L. However, when acid concentration become larger, emerging agglomerate of silver colloid reduce the quantities of enhanced-effect silver atoms, which makes SERS signals of CV decrease.

Summary

The spectra intensity of SERS for CV with changing the acid concentrations was studied. The SERS spectra intensity intially ascended and then descended with the acid concentration increasing in the CV - silver colloid system, which indicated a maximum value of SERS spectra. The phenomenon was considered to be associated with the interaction between hydrogen ions and CV, which may influenced the SERS signals.

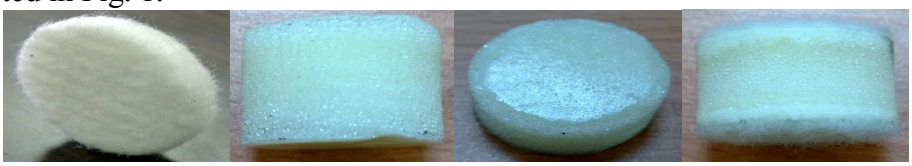
Keywords: absorption coefficient, nonwoven, foam, PU composite board, impedance tube.

Abstract: This article completely investigates from nonwoven to PET/PU composite board on the variations of absorption coefficient by using standard impedance tube with four microphones. Recently, PET/PU composite board is becoming one popular and functional material because of the high flexibility in the abilities, such as thermal-protection, chemical-proof, acoustic-resistance and etc.. Thus, it is important to realize the variations of absorption capability from single material to complete composite material, and feedback some suggestions to the designer. Results shows that nonwoven only has a stable increase in absorption coefficient with the frequencies because of the inherent porous characteristics. With the substantial properties, foam has lower absorption coefficient and two peaks occurring in the higher frequencies. Both two peaks are caused by the resonance between wave and foam at specified frequency. With an additional nonwoven in the rear side of composite foam, absorption coefficient of PET/PU composite board will effectively increase. Based on the diverse applications, absorption coefficient of PET/PU composite board can be flexible modulated to consistent with the requirements.



Introduction

With recent rapid advancement of techniques, human life had definitely improved and became more and more convenient. Meanwhile, the situation of some pollution, such as air, water, noise and etc., are more and more serious and emphasized recently, especially in the factories. One of common example is that the noise coming from working machine will jeopardize workman's hearing and cause occupational disease. Thus, the techniques and limitations of noise control is derived and becoming a standard [1]. At present, passive noise control which utilizes the internal structures of composite material and places around the noisy machine to resist or block the noise transmission is one cheaper, useful, and popular method [2]. Plenty researches are focused on the inventions of diverse composite material, such as polyethylene teraphthalate (PET), thermoplastic polyurethane (TPU) honeycomb grid, or polyurethane (PU) foam [3,4]. This article was conducted to explore the sound absorption capabilities beginning from single material of nonwoven and foam to the composite material of nonwoven-foam and nonwoven-foam-nonwoven. The influence of the internal organizations and structures of composite material will also be completely discussed.

Experiments

Material preparations and experiments

All of the experimental materials, such as flame-retardant polyester (PET) fiber and porous-structure Polyurethane (PU), were provided by Far Eastern New Century Corporation and Zhongxing Chemical, Taiwan, respectively. In the part of nonwoven, flame-retardant PET composite nonwoven fabrics were fabricated by 6D flame-retardant PET fibers after the processes of opening, blending, carding, lapping, and needle-punching (100 needles/min). In the part of foam, based on the mixture of Polyol and Isocyanate with the optimal percentage of 1:1, porous-structure Polyurethane foam can be made by the foaming and curing processes. During the foam processing, various bulk density of foam can also be controlled and modulated. PU composite boards, finally, can be completed by the compounds of flame-retardant PET mesh composite fabric and PU foam. All the samples are listed in Fig. 1.

Fig. 1. Samples; (a) nonwoven only; (b) foam only; (c) foam-nonwoven; (d) nonwoven-foam-nonwoven.

Testing by impedance tube

Absorption coefficient which is often utilized to assess if this material belongs to an absorption material is an important parameter. A useful tool, impedance tube, is not only usually used to obtain absorption coefficient but also serve as standard processes, such as ASTM E 1050-95. Due to the smooth, nonporous, and dusty-free inside the tube, wave energy with low attenuation inside the tube can be guaranteed, and precise results for material characteristics can be obtained. In this article, the impedance tube with 29 mm in diameter, Brüel & Kjær, type 4206T shown in Fig. 2, will be utilized to investigate the variations of absorption coefficient for these five composite material. Based on the geometric limitations of tube, all of the testing results are focused on the frequency range between 500 Hz to 6,400 Hz.

Discussion

Absorption characteristics for single nonwoven and signal foam

With different conditions behind the material in the tube, the absorption coefficient of different material, shown in Fig. 3, will be much different. Based on the condition with reflected board behind the nonwoven shown in Fig. 3(a), the absorption coefficient will increase with the frequencies instead of the constant value (0.8) which can be found under the condition without reflected board. Theoretically, nonwoven which is one of common porous material should belong to an absorption material, and have the capability of absorbing sound. If the reflected board locates closely behind the material, wave or sound passing through the material and immediately reflecting back to the tube, especially for the wave with longer wavelength or lower frequencies. Thus, the absorption coefficient will be much minor in the lower frequencies. With the increase of frequencies(> 1,500 Hz), the respective wavelength will become shorter enough, and its energy can be dissipated by the holes inside the nonwoven itself. Without the reflected board, there is no reflection of wave and dissipation

of energy during the wave passing the nonwoven. The absorption coefficient of nonwoven should be constant in the frequency ranges. However, this situation will not be found in the material with high density or solid construction, such as foam with 50% bulk density shown in Fig. 3(b). Thus, based on the different applications and compositions with porous material, the absorption capability of composite material will be much different and should be carefully paid attention.

(a) (b)

Fig.3. Absorption coefficients for signal material: (a) Nonwoven; (b) Foam with 50% bulk density.
(Note: Both lowercase letter, h and a, attached behind of A represent the conditions behind the material with and without reflected board, respectively.)

With foam only testing in the tube, Fig.3(b) shows that the absorption coefficient will increase slowly with the frequencies. In other words, foam with 50% bulk density can be recognized as the material with the ability of absorption only with the frequency above 3,000 Hz. This absorbing capability is coming from the inherent holes inside the foam in the initial foaming processes. These holes have enough abilities to limit the motions or dissipate the energy of wave in the shorter wavelength(higher frequencies). In addition, two peaks which also represent the higher absorption capability can be observed at 3,100 Hz and 5,600 Hz. The amplitude of peaks will reduce with the frequencies evidently. The phenomenon of both abrupt increments can be conjectured that the wave in the specified frequency have enough ability to enter the foam material, and be just consistent with the internal size and construction of foam. Then, the resonant phenomenon inside the foam occurs, and wave energy further dissipates with the resonance. By the observation of above results, thus, foam with different bulk density is useful to deal with the absorption in the specified frequency.

Absorption coefficient for the both arrangements between nonwoven and foam

Fig. 4 shows the change of absorption coefficients for both arrangements between nonwoven and foam with 50% bulk density. Obviously, absorption coefficient obtained under the arrangement of foam-nonwoven is higher than that under the arrangement of nonwoven-foam, especially above 1,500 Hz. This is because that the adhesive layer existed between foam and nonwoven will form a higher reflected interface to resist the wave propagation. For the nonwoven-foam type, this layer is located in front of the foam-nonwoven type. Thus, most parts of wave energy had been blocked to enter to the foam. In addition, similar to the results for foam only, two peaks possibly resulted from the resonance between foam and specific frequency of wave in the higher frequencies can also be found.

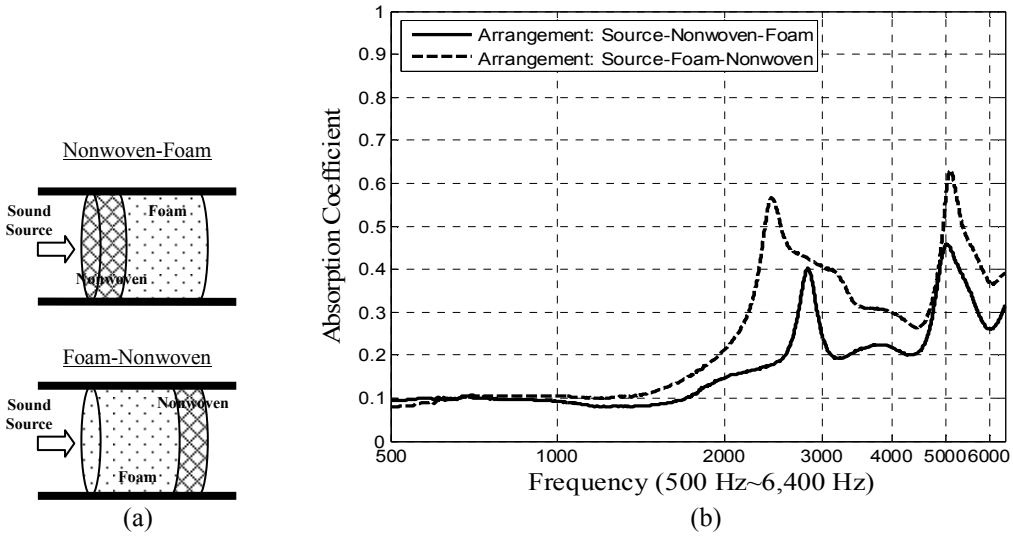

Fig. 4. Absorption coefficient for the composite material with 50 % bulk density in foam; (a) both arrangements; (b) nonwoven-foam(full line) and foam- nonwoven(dashed line).

Absorption coefficient for nonwoven-Foam-Nonwoven with various bulk density

The functional PU composites board with nonwoven layers glued on the both sides of foam can be usually found in the practical applications, especially in the chemical proof, mechanical impact-resistance, thermal protection and etc.. Fig. 5 shows the related performance of absorption coefficient for this composite material with various bulk densities. With the increase of bulk density in foam, the frequency of first peak of absorption coefficient decreases and converges gradually. Because of an additional nonwoven glued on the other side of foam, the level of absorption coefficient will be lower than that in Fig. 4 which only one nonwoven is located on one side of foam. The peak cause by the resonance between propagating wave and foam can also be obtained in this case. After this peak frequency, absorption coefficient abruptly decreases and then increases again until the next resonant frequency coming. Due to the artificial error in the processing and experiment, the variations of absorption coefficient between first and second peak frequency can be found to be irregular instead of the with 60% foam.

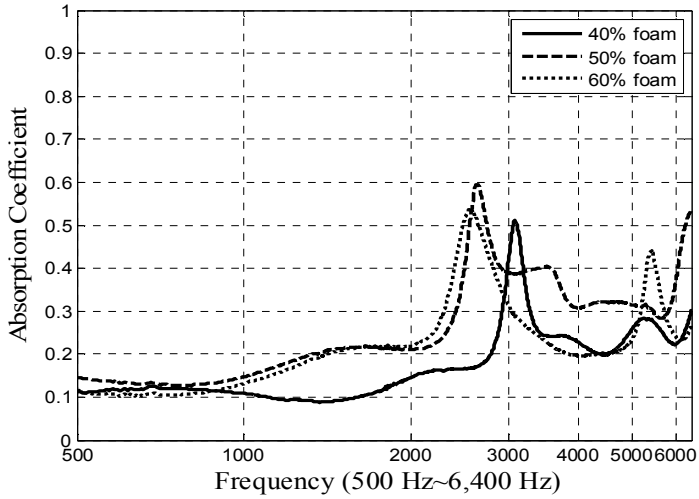

Fig. 5. Absorption coefficient with three kinds of bulk density in foam.

Comparisons

Fig. 6 integrates and collects all the performance of absorption coefficient discussed above. Obviously, Due to the inherent porous characteristics, the level of absorption coefficient of only nonwoven is the highest, and increases dramatically with the frequency. For foam only, absorption coefficient is not only lower than nonwoven but more importantly, two peaks in the higher

frequencies can also be obtained because of the resonance between propagating wave and size of foam inside the impedance tube. Due to the influence of glue layer between nonwoven and foam, absorption coefficient will reduce especially in the case of nonwoven-foam instead of foam-nonwoven. However, when the foam are glued with nonwoven in the both side of foam, the level of absorption coefficient will be increase in evidence. It is conjectured that the additional contribution and increase of absorption coefficient is coming from the rear side of nonwoven.

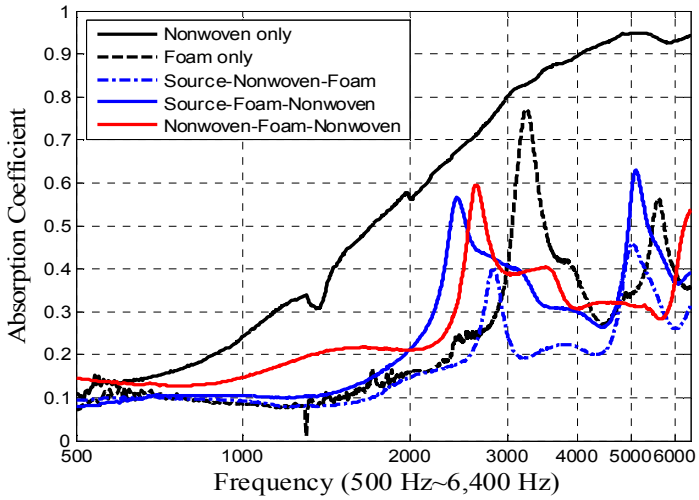

Fig. 6. Comparisons for all composite board

Summary

This article successfully and comprehensively investigates the performance of absorption coefficient from nonwoven to nonwoven-foam-nonwoven. Theoretically, the material such as nonwoven had highest absorption capability because of the porous characteristics in the organization. With the increase of frequency, these porous characteristics inside the material has more possibilities to limit and dissipate these propagating wave. Thus, level will increase with frequencies. Due to the foam processing and bulk density, foam which has more solid properties inside will reduce the absorption capability and caused two abrupt peaks in the higher frequencies because of resonance between structure and wave. With the nonwoven located in the rear side of PU composite board, absorption coefficient will obviously increase. Therefore, based on the diverse applications, the characteristics of functional PU composite such as absorption capability can be controlled and modulated artificially. Of course, some important and potential parameters, such as thickness of foam and nonwoven, which will cause the variations of absorption coefficient should be investigated in the future.

Keywords: Functionally graded orthotropic material, coating-substrate structure, mode I crack problem, singular integral equation

Abstract: In this paper, the Fourier integral transform-singular integral equation method is presented for the Mode I crack problem of the functionally graded orthotropic coating-substrate structure. The elastic property of the material is assumed vary continuously along the thickness direction. The principal directions of orthotropy are parallel and perpendicular to the boundaries of the strip. Numerical examples are presented to illustrate the effects of the crack length, the material nonhomogeneity and the thickness of coating on the stress intensity factors.

Introduction

The analysis of functionally graded materials has become a subject of increasing importance motivated by a number of potential benefits from the use of such novel materials in a wide range of modern technological practices. The major advantages of the graded material, especially in elevated temperature environments stem from the tailoring capability to produce a gradual variation of itsthermo mechanical properties in the spatial domain. A great efforts have been made to study the fracture behavior of FGMs [1-5]. As it is reported in the literature [6, 7], the graded materials are rarely isotropic because of the nature of techniques used in fabricating them. Thus, it is necessary to consider the anisotropic character when studying the failure behaviors of FGMs. Guo et al. [8] investigated the mode I surface crack problem for an orthotropic graded strip. H. M. Xu et al. [9] studied the problems of a power-law orthotropic and half-space functionally graded material (FGM) subjected to a line load. In the paper [10], asymptotic analysis coupled with Westergaard stress function approach is used to develop quasistatic stress fields for a crack oriented along one of the principal axes of inhomogeneous orthotropic medium. Kim and Paulino [11, 12] examined mixed-mode stress intensity factors for cracks arbitrarily oriented in orthotropic FGMs using modified crack closure method and the path-independent J_k -integral, respectively. Though there are lots of papers related to the crack problem of orthotropic functionally graded materials, very few papers on the plane crack problem of a functionally graded strip with a crack perpendicular to the boundary are published. It is very significant to study this kind of crack problem, since the geometry can be used as an approximation to a number of structural components and laboratory specimens, at the same time in line with the result of the Kawasaki and Watanabe[13]'s experiments about the thermal fracture behavior of metal/ceramic functionally graded materials(PSZ/IN 100 FGMS and PSZ/Inco 718 FGMs), the sequence of sapling behavior was found to be: crack vertical to the sample surface formed during cooling, then transverse crack formed in graded layer during heating, and subsequent growth of transverse cracks and their coalescence led eventually the ceramic coating to spall. Therefore, the surface crack problem is a very important issue to be considered during the design of FGMs. In these papers, the Mode I crack problem for a functionally graded orthotropic coating-substrate structure will be presented and the results could be useful in the laboratory test and the design of the orthotropic functionally graded materials.

Formulation of the Problem

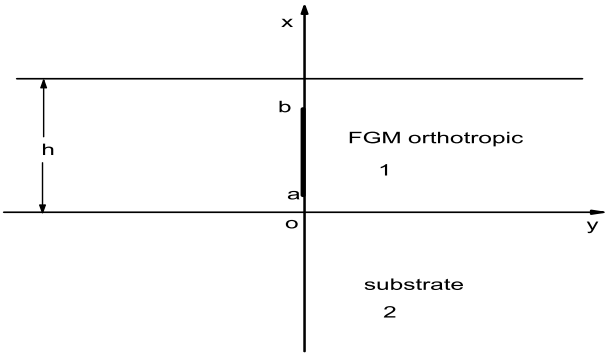

Figure 1: The geometry of the mode I crack problem for the functionally graded orthotropic substrate-coating structure.

As shown in Fig.1: A functionally graded orthotropic strip with properties varying in the x-direction bonded to a half infinite orthotropic elastic substrate. The strip is infinite along the y-axis and has a thickness h along x-axis. The principal directions of orthotropy are parallel and perpendicular to the boundaries of the strip. The material properties are defined as

$$c_{11}(x)=c_{110}e^{\delta x},c_{12}(x)=c_{120}e^{\delta x},c_{22}(x)=c_{220}e^{\delta x},c_{66}(x)=c_{660}e^{\delta x}, \tag{1}$$

Where c_{110}, c_{120}, c_{220}, c_{660} and δ are constants. c_{110}, c_{120}, $c_{220}$and c_{660} are the material parameters of y = 0, δ is the gradient parameters of functionally graded material.

The general constitutive relation can be written as

$$\sigma_{1xx}=c_{11}(x)\frac{\partial u}{\partial x}+c_{12}(x)\frac{\partial v}{\partial y},\ \ \sigma_{1yy}=c_{12}(x)\frac{\partial u}{\partial x}+c_{22}(x)\frac{\partial v}{\partial y},\ \ \sigma_{1xy}=c_{66}(x)(\frac{\partial u}{\partial y}+\frac{\partial v}{\partial x}), \tag{2}$$

The equilibrium equation in terms of the displacements can be given as:

$$\frac{\partial\sigma_{1xx}}{\partial x}+\frac{\partial\sigma_{1xy}}{\partial y},\ \ \frac{\partial\sigma_{1yy}}{\partial y}+c_{22}(x)\frac{\partial\sigma_{1xy}}{\partial x}=0 \tag{3}$$

make use of the equation Eqs. (1), (2) and (3), it can be obtained that

$$\begin{aligned}&c_{11}(x)\frac{\partial^2u}{\partial x^2}+c_{66}(x)\frac{\partial^2u}{\partial y^2}+[c_{11}(x)+c_{66}(x)]\frac{\partial^2v}{\partial x\partial y}+c_{11}(x)\delta\frac{\partial u}{\partial x}+c_{12}(x)\delta\frac{\partial v}{\partial y}=0,\\&c_{22}(x)\frac{\partial^2v}{\partial y^2}+c_{66}(x)\frac{\partial^2v}{\partial x^2}+[c_{12}(x)+c_{66}(x)]\frac{\partial^2u}{\partial x\partial y}+c_{66}(x)\delta\frac{\partial u}{\partial y}+c_{66}(x)\delta\frac{\partial v}{\partial x}=0,\end{aligned} \tag{4}$$

if let the $\delta=0$, then the equations of the elastic substrate can be obtained.

The mixed boundary conditions of the problem in Fig.1 can be written as

$$\begin{aligned}&\sigma_{1xx}(h,y)=0,\sigma_{1xy}(h,y)=0,\sigma_{1xx}(0,y)=\sigma_{2xx}(0,y),\\&\sigma_{1xy}(0,y)=\sigma_{2xy}(0,y)=0,u_1(0,y)=u_2(0,y),v_1(0,y)=v_2(0,y)\end{aligned} \tag{5}$$

$$\begin{aligned}&\sigma_{2xx}(x,y)=0,\sigma_{2xy}(x,y)=0,x\to-\infty,\\&\sigma_{1xy}(x,0)=0,\ \ 0<x<h,\ \sigma_{1yy}(x,0)=-\sigma_0(x),\ \ a<x<b,\end{aligned} \tag{6}$$

$$v_1(x,0)=0,0<x<a,\ b<x<h \tag{7}$$

By use of the Fourier transform method and thinking of the Eq. (6), the following displacement forms can be obtained, for functionally graded coating:

$$u_1=\frac{1}{2\pi}\int_{-\infty}^{\infty}\sum_{j=3}^{4}E_{1j}(s)A_{1j}e^{\lambda_{1j}(s)y-isx}ds+\frac{2}{\pi}\int_0^{\infty}\sum_{j=1}^{4}E_{2j}(\alpha)A_{2j}e^{\lambda_{2j}(\alpha)x}\cos\alpha y d\alpha,$$
$$v_1=\frac{1}{2\pi}\int_{-\infty}^{\infty}\sum_{j=3}^{4}A_{1j}(s)e^{\lambda_{1j}(s)y-isx}ds+\frac{2}{\pi}\int_0^{\infty}\sum_{j=1}^{4}A_{2j}e^{\lambda_{2j}(\alpha)x}\sin\alpha y d\alpha, \quad (8)$$

for elastic substrate:

$$u_2=\frac{2}{\pi}\int_0^{\infty}\sum_{j=1}^{2}A_{3j}(\alpha)E_{3j}e^{\lambda_{3j}(\alpha)x}\cos\alpha y d\alpha,$$
$$v_2=\frac{2}{\pi}\int_0^{\infty}\sum_{j=1}^{2}A_{3j}(\alpha)e^{\lambda_{3j}(\alpha)x}\sin\alpha y d\alpha, \quad (9)$$

where

$$E_{1j}=\frac{\left[c_{660}(s+i\delta)s-c_{220}\lambda_{1j}^2\right]i}{\left[c_{120}s+c_{660}(s+i\delta)\right]\lambda_{1j}},E_{2j}=\frac{c_{660}\lambda_{2j}(\lambda_{2j}+\delta)-\alpha^2c_{220}}{\alpha\left[c_{120}\lambda_{2j}+c_{660}(\lambda_{2j}+\delta)\right]},E_{3j}=\frac{c_{660}\lambda_{3j}^2-\alpha^2c_{220}}{\alpha(c_{120}+c_{660})\lambda_{3j}},$$

$$\lambda_{1j}=-\sqrt{-\frac{\Omega_{11}}{2}\pm\frac{1}{2}\sqrt{\Omega_{11}^2-4\Omega_{12}}},\lambda_{2j}=\frac{-\delta\pm\sqrt{\delta^2-2\Omega_{21}\pm2\sqrt{\Omega_{21}^2-4\Omega_{22}}}}{2},\lambda_{3j}=\frac{\sqrt{2}}{2}\sqrt{-\Omega_{31}^2-4\Omega_{32}},$$

$$(j=1,\cdots4,)\ \Omega_{11}=\frac{\left(c_{120}^2-c_{120}c_{220}\right)s(s+i\delta)+\left(2s^2+2is\delta-\delta^2\right)c_{120}c_{660}}{c_{220}c_{660}},\Omega_{12}=\frac{c_{110}s^2(s+i\delta)^2}{c_{220}},$$

$$\Omega_{21}=\frac{\left(c_{120}^2-c_{120}c_{220}+2c_{120}c_{660}\right)\alpha^2}{c_{110}c_{660}},\Omega_{22}=\left(\frac{c_{220}}{c_{110}}\alpha^2+\frac{c_{120}}{c_{110}}\delta^2\right)\alpha^2,\Omega_{31}=\left(\frac{c_{120}^2}{c_{110}c_{660}}+2\frac{c_{120}}{c_{110}}-\frac{c_{220}}{c_{660}}\right)\alpha^2,$$

$\Omega_{32}=\frac{c_{120}}{c_{110}}\alpha^4$, $A_{ij}\ (i=1,2,3,\ j=1,\cdots,4)$ are unknown functions, which can be solved by the boundary conditions. To obtain the integral equations, let's introduce the following auxiliary function

$$g(x)=\frac{\partial}{\partial x}v_1(x,0), \quad (10)$$

and $g(x)$ subjected to the following single-valuedness conditions

$$\int_a^{vb}g(t)dt=0 \quad (11)$$

By using Eqs. (7), (10) and applying the Fourier transform to Eq. (10), it can be obtained that

$$A_{13}=q_{13}\int_a^b g(u)e^{isu}du,\ A_{14}=q_{14}\int_a^b g(u)e^{isu}du, \quad (12)$$

Where

$$q_{13}=\frac{-i\left(c_{120}s^2+c_{220}\lambda_{14}^2\right)}{c_{220}s\left(\lambda_{13}^2-\lambda_{14}^2\right)},\ q_{14}=\frac{i\left(c_{120}s^2+c_{220}\lambda_{13}^2\right)}{c_{220}s\left(\lambda_{13}^2-\lambda_{14}^2\right)}.$$

Then by residue theorem and the boundary conditions, we can get the following linear algebraic equations

$$\begin{vmatrix} B_{21}e^{\lambda_{21}h} & B_{22}e^{\lambda_{22}h} & B_{23}e^{\lambda_{23}h} & B_{24}e^{\lambda_{24}h} & 0 & 0 \\ F_{21}e^{\lambda_{21}h} & F_{22}e^{\lambda_{22}h} & F_{23}e^{\lambda_{23}h} & F_{24}e^{\lambda_{24}h} & 0 & 0 \\ B_{21} & B_{22} & B_{23} & B_{24} & -B_{31} & -B_{32} \\ F_{21} & F_{22} & F_{23} & F_{24} & -F_{31} & -F_{32} \\ E_{21} & E_{22} & E_{23} & E_{24} & -E_{31} & -E_{32} \\ 1 & 1 & 1 & 1 & 1 & 1 \end{vmatrix} \begin{vmatrix} A_{21} \\ A_{22} \\ A_{23} \\ A_{24} \\ A_{25} \\ A_{26} \end{vmatrix} = \begin{vmatrix} R_1 \\ R_2 \\ R_3 \\ R_4 \\ R_5 \\ R_6 \end{vmatrix}, \tag{13}$$

where

$$R_1(u) = \frac{\left(-c_{120}^2 + c_{110}c_{220}\right)\alpha^2\lambda_{23}}{c_{110}\left(\lambda_{23}-\lambda_{21}\right)\left(\lambda_{23}-\lambda_{22}\right)\left(\lambda_{23}-\lambda_{24}\right)}e^{-\lambda_{23}(u-h)} + \frac{\left(-c_{120}^2 + c_{110}c_{220}\right)\alpha^2\lambda_{24}}{c_{110}\left(\lambda_{24}-\lambda_{21}\right)\left(\lambda_{24}-\lambda_{22}\right)\left(\lambda_{24}-\lambda_{23}\right)}e^{-\lambda_{24}(u-h)},$$

$$R_2(u) = \frac{\left(-c_{120}^2 + c_{110}c_{220}\right)\alpha\lambda_{23}\left(\lambda_{23}+\delta\right)}{c_{110}\left(\lambda_{23}-\lambda_{21}\right)\left(\lambda_{23}-\lambda_{22}\right)\left(\lambda_{23}-\lambda_{24}\right)}e^{\lambda_{23}(h-u)} + c_{110}\left(\lambda_{24}-\lambda_{21}\right)\left(\lambda_{24}-\lambda_{22}\right)\left(\lambda_{24}-\lambda_{23}\right)e^{\lambda_{24}(h-u)},$$

$$R_3(u) = \frac{-\left(-c_{120}^2 + c_{110}c_{220}\right)\alpha^2\lambda_{21}}{c_{110}\left(\lambda_{21}-\lambda_{22}\right)\left(\lambda_{21}-\lambda_{23}\right)\left(\lambda_{21}-\lambda_{24}\right)}e^{-\lambda_{21}u} + \frac{-\left(-c_{120}^2 + c_{110}c_{220}\right)\alpha^2\lambda_{22}}{c_{110}\left(\lambda_{22}-\lambda_{21}\right)\left(\lambda_{22}-\lambda_{23}\right)\left(\lambda_{22}-\lambda_{24}\right)}e^{-\lambda_{22}u},$$

$$R_4(u) = \frac{\left(-c_{120}^2 + c_{110}c_{220}\right)\alpha\lambda_{21}\left(\lambda_{21}+\delta\right)}{c_{110}\left(\lambda_{21}-\lambda_{22}\right)\left(\lambda_{21}-\lambda_{23}\right)\left(\lambda_{21}-\lambda_{24}\right)}e^{-\lambda_{21}u} + \frac{\left(-c_{120}^2 + c_{110}c_{220}\right)\alpha^2\lambda_{22}\left(\lambda_{22}+\delta\right)}{c_{110}\left(\lambda_{22}-\lambda_{21}\right)\left(\lambda_{22}-\lambda_{23}\right)\left(\lambda_{22}-\lambda_{24}\right)}e^{-\lambda_{22}u},$$

$$R_5(u) = \frac{1}{c_{110}}\left[\frac{c_{120}\lambda_{21}^2 + 2\delta c_{120}\lambda_{21} + c_{120}\delta^2 + \alpha^2 c_{220}}{\left(\lambda_{21}-\lambda_{22}\right)\left(\lambda_{21}-\lambda_{23}\right)\left(\lambda_{21}-\lambda_{24}\right)}e^{-\lambda_{21}u} + \frac{c_{120}\lambda_{22}^2 + 2\delta c_{120}\lambda_{22} + c_{120}\delta^2 + \alpha^2 c_{220}}{c_{110}\left(\lambda_{22}-\lambda_{21}\right)\left(\lambda_{22}-\lambda_{23}\right)\left(\lambda_{22}-\lambda_{24}\right)}e^{-\lambda_{22}u}\right],$$

$$R_6(u) = \frac{-\alpha\left(-c_{120}^2 + c_{110}c_{220} - c_{120}c_{660}\right)\lambda_{21}^2}{c_{110}c_{660}\lambda_{21}\left(\lambda_{21}-\lambda_{22}\right)\left(\lambda_{21}-\lambda_{23}\right)\left(\lambda_{21}-\lambda_{24}\right)}e^{-\lambda_{21}u} + \frac{-\alpha\left(-c_{120}^2 + c_{110}c_{220} - c_{120}c_{660}\right)\lambda_{22}^2}{c_{110}c_{660}\lambda_{22}\left(\lambda_{22}-\lambda_{22}\right)\left(\lambda_{22}-\lambda_{23}\right)\left(\lambda_{22}-\lambda_{24}\right)}e^{-\lambda_{22}u}$$

$$+\frac{\alpha\delta\lambda_{21}\left(c_{120}^2 - c_{110}c_{220} + 2c_{120}c_{660}\right) - \alpha c_{660}\left(\delta^2 c_{120} + c_{220}\alpha^2\right)\lambda_{21}^2}{c_{110}c_{660}\lambda_{21}\left(\lambda_{21}-\lambda_{22}\right)\left(\lambda_{21}-\lambda_{23}\right)\left(\lambda_{21}-\lambda_{24}\right)}e^{-\lambda_{21}u} + \frac{\alpha\left(\delta^2 c_{120} + c_{220}\alpha^2\right)}{c_{110}\lambda_{21}\lambda_{22}\lambda_{23}\lambda_{24}}$$

$$+\frac{\alpha\delta\lambda_{22}\left(c_{120}^2 - c_{110}c_{220} + 2c_{120}c_{660}\right) - \alpha c_{660}\left(\delta^2 c_{120} + c_{220}\alpha^2\right)}{c_{110}c_{660}\lambda_{22}\left(\lambda_{22}-\lambda_{21}\right)\left(\lambda_{22}-\lambda_{23}\right)\left(\lambda_{22}-\lambda_{24}\right)}e^{-\lambda_{22}u}$$

During the process of obtaining Eq. (13), the integral identities[14]

$$\begin{aligned} &\int_0^\infty e^{-px}\sin\left(qx+\lambda\right)dx = \frac{1}{p^2+q^2}\left(q\cos\lambda + p\sin\lambda\right), \\ &\int_0^\infty e^{-px}\sin\left(qx+\lambda\right)dx = \frac{1}{p^2+q^2}\left(q\cos\lambda + p\sin\lambda\right), \end{aligned} \qquad p>0, \tag{14}$$

are used. The B_j, C_j and F_j are some expressions of material consistent. Then the solution of the unknown functions can be obtained. Substitute the solution of the above equation and using the conditions of the crack surface, after considering the asymptotic when $s\to\infty$ and $\alpha\to 0$, the following equation can be obtained

$$\frac{1}{\pi}\int_a^b\left[-\frac{\mathrm{Im}\left(\omega_1\right)}{u-x} + h_1\left(u,x\right) + 2K_{2s} + 2h_1\left(u,x\right)\right]g\left(u\right)du = -\sigma_0\left(x\right)e^{-\delta x}\ , \tag{15}$$

Where

$$\omega_1 = \frac{ic_{660}\left(c_{120}+c_{220}p_{11}^2\right)\left(c_{120}+c_{220}p_{12}^2\right)}{c_{220}\left(c_{120}+c_{220}\right)p_{11}p_{12}\left(p_{11}+p_{12}\right)}, h_1\left(u,x\right) = \frac{1}{2}\int_{-\infty}^{\infty}\left(\sum_{j=3}^{4}C_{1j}q_{1j} - \omega_1\right)e^{is(u-x)}ds$$

$$K_{2s} = \left[\frac{\Lambda_1}{p_{21}\left(x+u\right)} + \frac{\Lambda_2}{p_{21}x+p_{22}u} + \frac{\Lambda_3}{p_{22}x+p_{21}u} + \frac{\Lambda_4}{p_{22}\left(x+u\right)}\right], h_2\left(u,x\right) = \int_0^\infty[\sum_{j=3}^{4}C_{2j}e^{\lambda_{2j}x}A_{2j} - \Lambda_1 e^{-p_{21}\alpha(x+u)}$$

$$-\Lambda_2 e^{-\alpha(p_{21}x+p_{22}u)}-\Lambda_3 e^{-\alpha(p_{22}x+p_{21}u)}-\Lambda_4 e^{-p_{22}\alpha(x+u)}]d\alpha,$$

$$\Lambda_1=\frac{1}{4}\left(c_{120}p_{21}^2+c_{220}\right)\left(c_{120}c_{660}+c_{120}^2-c_{110}c_{220}+c_{110}c_{660}p_{22}^2\right)\left[-c_{110}c_{660}p_{21}^4+\left(c_{110}c_{220}-c_{120}^2-2c_{120}c_{660}\right)p_{21}^2-c_{220}c_{660}\right]$$

$$\frac{1}{c_{660}c_{110}^2p_{21}^2\left(c_{660}+c_{120}\right)\left(p_{21}+p_{22}\right)^2\left(p_{21}-p_{22}\right)^2},\ \Lambda_2=\frac{1}{4}\left(c_{120}p_{21}^2+c_{220}\right)[-c_{110}c_{660}p_{22}^4+\left(c_{110}c_{220}-c_{120}^2-2c_{120}c_{660}\right)p_{22}^2$$

$$-c_{220}c_{660}]\left(c_{110}c_{220}-c_{110}c_{660}p_{21}p_{22}-c_{120}^2-c_{120}c_{660}\right)\frac{1}{c_{660}c_{110}^2p_{22}^2\left(c_{660}+c_{120}\right)\left(p_{21}+p_{22}\right)^2\left(p_{21}-p_{22}\right)^2},$$

$$\Lambda_3=\frac{1}{4}\left(c_{120}p_{22}^2+c_{220}\right)\left[-c_{110}c_{660}p_{21}^4+\left(c_{110}c_{220}-c_{120}^2-2c_{120}c_{660}\right)p_{21}^2-c_{220}c_{660}\right]$$

$$\left(c_{110}c_{220}-c_{110}c_{660}p_{21}p_{22}-c_{120}^2-c_{120}c_{660}\right)\frac{1}{c_{660}c_{110}^2p_{21}^2\left(c_{660}+c_{120}\right)\left(p_{21}+p_{22}\right)^2\left(p_{21}-p_{22}\right)^2},$$

$$\Lambda_4=-\frac{1}{4}\left(c_{120}p_{22}^2+c_{220}\right)\left[-c_{110}c_{660}p_{22}^4+\left(c_{110}c_{220}-c_{120}^2-2c_{120}c_{660}\right)p_{22}^2-c_{220}c_{660}\right]$$

$$\left(c_{110}c_{220}-c_{110}c_{660}p_{21}^2-c_{120}^2-c_{120}c_{660}\right)\frac{1}{c_{660}c_{110}^2p_{22}^2\left(c_{660}+c_{120}\right)\left(p_{21}+p_{22}\right)^2\left(p_{21}-p_{22}\right)^2},$$

$$p_{1j}=-\frac{\sqrt{2}}{2}\xi_{11}\sqrt{aa_1\pm bb_1},\ \xi_{1j}=sign\left[\mathrm{Re}\sqrt{aa_1\pm bb_1}\right],\ p_{2j}=\frac{\sqrt{2}}{2}\xi_{21}\sqrt{aa_2\pm bb_2},\ \xi_{2j}=sign\left[\mathrm{Re}\sqrt{aa_2\pm bb_2}\right],$$

$$\left(j=1,2\right),aa_1=\frac{c_{110}c_{220}-c_{120}\left(c_{120}+2c_{660}\right)}{c_{220}c_{660}},aa_2=\frac{c_{110}c_{220}-c_{120}^2-2c_{120}c_{660}}{c_{110}c_{660}},$$

$$bb_1=\frac{\sqrt{\left(c_{120}^2-c_{110}c_{220}\right)\left[\left(c_{120}+2c_{660}\right)^2-c_{110}c_{220}\right]}}{c_{220}c_{660}},bb_2=\frac{\sqrt{\left(c_{120}^2-c_{110}c_{220}\right)\left[\left(c_{120}+2c_{660}\right)^2-c_{110}c_{220}\right]}}{c_{110}c_{660}},$$

the Eq. (15) is the first kind of Fredholm integral equation, which can be solved by the method of [15]. The stress intensity factors of the internal crack tips can be express as

$$\begin{aligned}K_I(a)&=\lim_{x\to a}\sqrt{2(a-x)\sigma_{yy}(x,0)}=-\mathrm{Im}(\omega_{11})e^{\delta a}\sum_{n=1}^{N}a_n,\\ K_I(b)&=\lim_{x\to b}\sqrt{2(x-b)\sigma_{yy}(x,0)}=-\mathrm{Im}(\omega_{11})e^{\delta b}\sum_{n=1}^{N}a_n,\end{aligned}\tag{16}$$

For convenience, the SIFs are normalized by $\kappa_0=\sigma_0\sqrt{a_0h}$, where σ_0 is uniform crack surface pressure.

Numerical Results and Discussion

In the following analysis, we will study the influence of the length of the crack, the location of the crack, the functionally graded strip's width h and the gradient parameters of functionally graded material δ on the normalized stress intensity factors (SIFs) of the crack.

Firstly, the influence of the length of the crack and the gradient parameters of functionally graded material δ on the normalized stress intensity factors (SIFs) of the crack will be discussed. Here $h=5.0,\delta h=-1,0,1,2,c=0.4h$. It can be found in the Fig.2–Fig.3 that the normalized intensity factors of both crack tips $\mathrm{K}_I(a)$ and $\mathrm{K}_I(b)$ increases with the increase of the normalized half crack length a_0 and the gradient parameters of functionally graded material δ. Therefore, to prevent the coating crack from growing toward the interface, the gradient parameters of functionally graded material δ should be chosen as $\delta<0$.

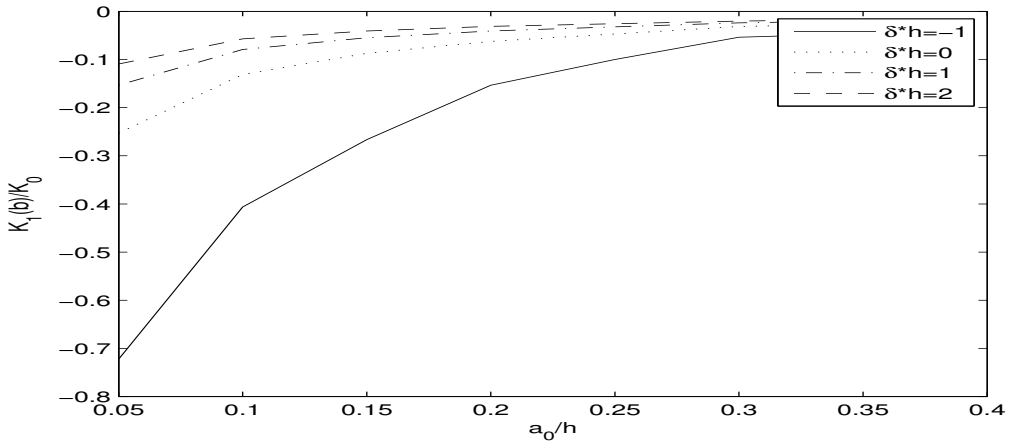

Figure 2: The normalized stress intensity factor $\mathrm{K}_I(b)$ versus $\frac{a_0}{h}$

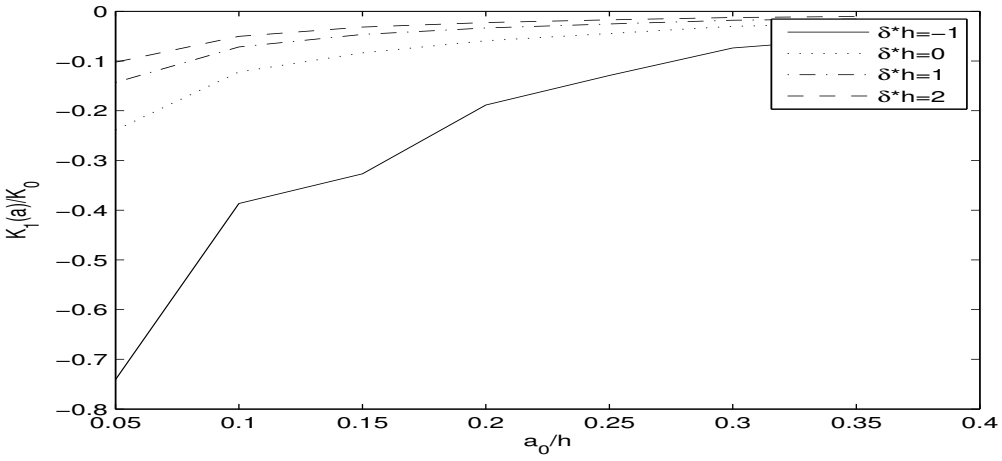

Figure 3: The normalized stress intensity $\mathrm{K}_I(a)$ versus $\frac{a_0}{h}$

Secondly, we will discuss the influence of the location of the crack on the normalized stress intensity factors (SIFs) of the crack. Here δh = 1, c = 0.5, 1, 1.5, 2. It can be found from Fig.4–Fig.5 that the normalized intensity factors of both crack tips $K_I(a)$ and $\mathrm{K}_I(b)$ increases with the increase of the $c=\frac{a+b}{2}$.

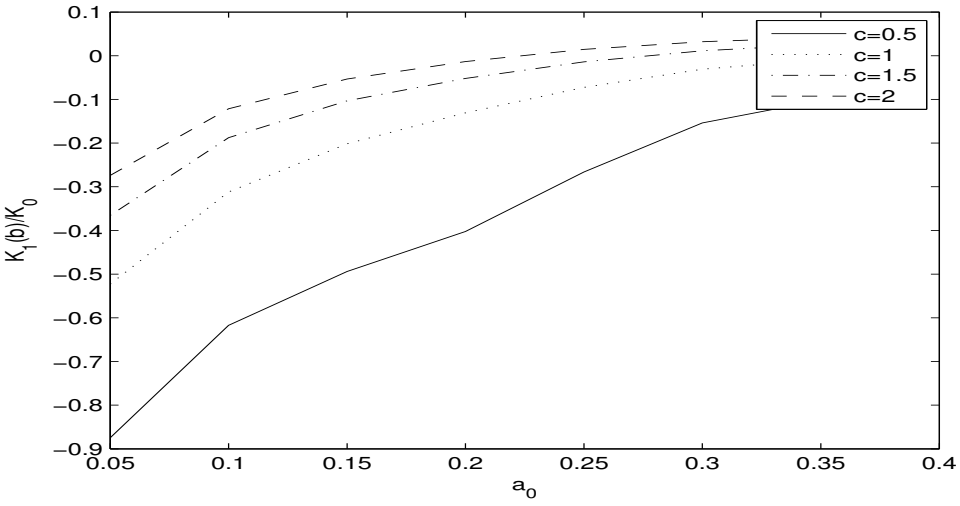

Figure 4: The normalized stress intensity $\mathrm{K}_I(b)$ versus a_0

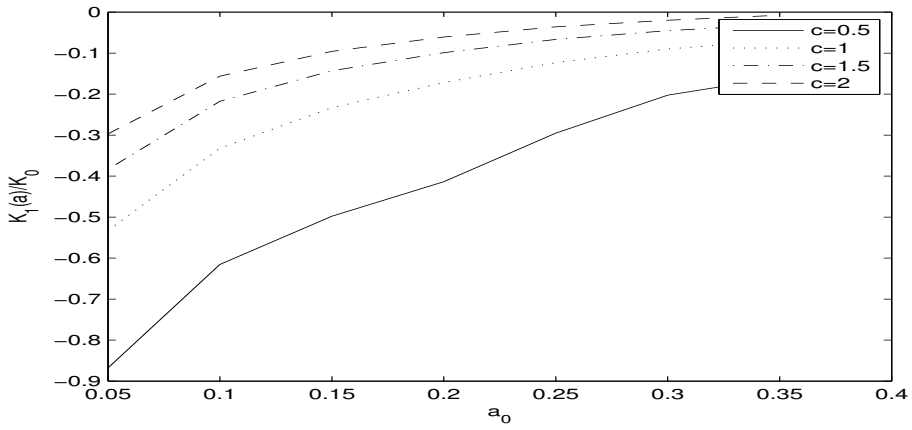

Figure 5: The normalized stress intensity $\mathrm{K}_I(a)$ versus a_0

Finally, we will discuss the influence of the width of the functionally graded orthotropic strip on the normalized stress intensity factors (SIFs) of the crack. Here The normalized stress intensity h= 1, 2, 3, 4, δh = 1, c = 0.5 . It can be found from the Fig.6–Fig.7 that the normalized intensity factors of both crack tips $\mathrm{K}_I(a)$ and $\mathrm{K}_I(b)$ decreases with the increase of the h, but as the increase of the strip width and the increase of the crack length, the effect is not obvious, so increasing the width of coating is not an effective way to restrain the expansion of the crack.

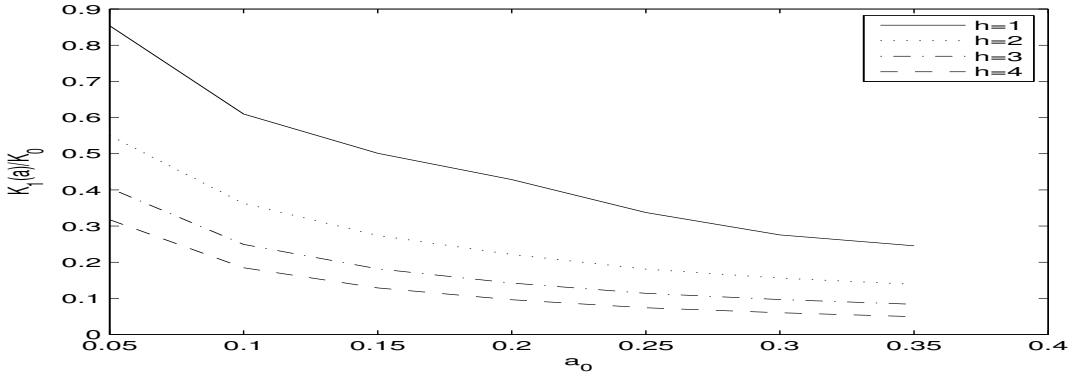

Figure 6: The normalized stress intensity $\mathrm{K}_I(a)$ versus a_0

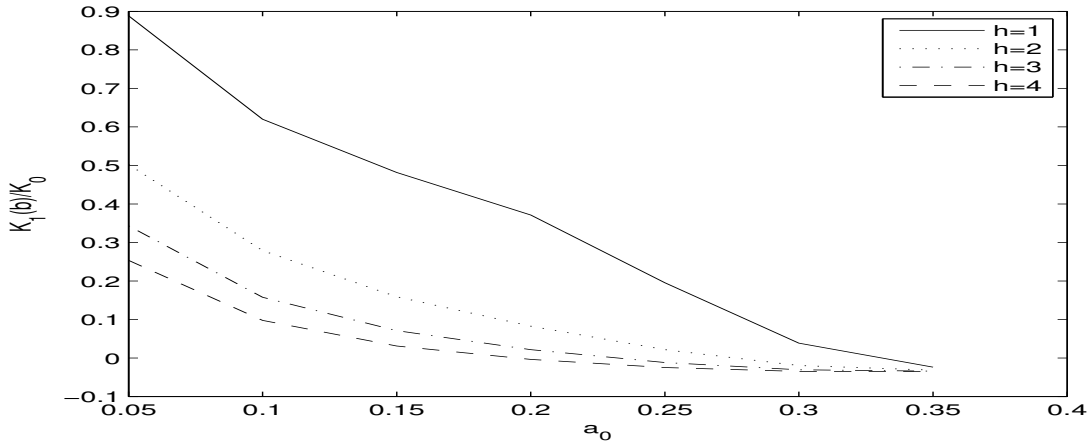

Figure 7: The normalized stress intensity $\mathrm{K}_I(b)$ versus a_0

Conclusion

In this paper, the mode I crack problem for a functionally graded orthotropic strip bonded to orthotropic substrate is studied analytically. The influences of the nonhomogeneity constants and geometric parameters on the stress intensity factors are investigated. The result may be help for the analysis and design of functionally graded orthotropic coating-substrate structures.

Keyword: Laser-induced fluorescence; temperature effect; solvent effect

Abstract.: The experiment was conducted to study the effects of concentration, temperature and solvent on the luminescence decay curves obtained in laser-induced fluorescence (LIF) experiment from fluorescent orange dye. Sample solutions of fluorescence dye were prepared by mixing with ethanol solvents at different concentration. The sample was illuminated with a radiation of 470 nm using a blue laser excitation source. Luminescence spectra were recorded using a compact fiber coupled CCD spectrometer and the results were analyzed.The results showed that both concentration and temperature affected the luminescence decay of orange dye in the same way. The luminescence decay was decreased when the concentration and temperature were increased.The appearance of peak positions was slighly shifted to higher wavelength (lower photon energy) when concentration were varied. Then the results of concentration effect were analyzed using peak fit, the appearance of peak positions was slightly shifted from 601.51 to 604.12, 607.64, and 618.44 nm at the concentration of 50, 60, 70 and 80 % by volume, respectively.

Introduction

Fluorescent dyes have the unique property of absorbing in the UV range and emitting in the visible range of the color spectrum. Each fluorescent dye has its own unique properties and emission spectrum of fluorescent dyes often vary with environmental conditions. Thus, many fluorescent dyes can be used as sensors to probe their local environments in biological and analytical applications. For example, coumarin [1], rhodamine [2], and oxazine [3] dyes are known to be efficiently quenched by the nucleobase guanosine (dG) and the amino acid tryptophan (Trp). In order to obtain an accurate indicator for fluorescent dyes, an accurate analysis of the color and fluorescence is necessary. Therefore, a system to measure the fluorescence spectra of high quality is needed. The current laser-induced fluorescent (LIF) system is one popular measurement system used [4].

The basic idea of LIF is simple. Light from a tunable laser impinged on the sample is to be investigated. As the frequency of the laser is changed, molecules within the irradiated portion of the sample will be excited to fluorescence whenever the spectral envelope of the laser overlaps an absorption line of the molecule [5]. Since the only excited molecules are those in the specific lower level(s) of the corresponding transition, the excitation is selective for this state or group of states. Hence, the "excitation spectrum" obtained by recording the fluorescent intensity as a function of wavelength reflects the relative populations of these different states. The excitation spectrum depends on the factors of environmental conditions such as concentration, temperature, pH value, molecular structure and solvent effect [6-8].

This experiment aims to study the effect of concentrations, temperature and solvent on the luminescence decays of fluorescence orange dye at different concentrations and temperatures by comparing the fluorescence properties of dye to the level of concentration and temperature in

wavelength-intensity relationship. In the last step all the results were analyzed by peak fitting in order to study the effects of concentration on the fluorescent dye.

Experimental procedure

An orange dye was used in this study. Sample solutions of fluorescence dye were prepared by mixing with ethanol at the concentration of 50, 60, 70 and 80 % by volume to investigate the concentration effect. To study the temperature effect, a mixture of fluorescence dye and ethanol solvents was kept constant at the 50 % by volume. The solutions were allowed to cure under ambient conditions for 1 h before the measurements. The fluorescence dye solution was illuminated with a radiation of 470 nm using a blue laser as an excitation source. Luminescence fluorescence spectra of dye solutions were recorded using a compact fiber coupled CCD spectrometer model BTC-110S and the temperature was increased from 25 to 55^{o}C with a step size of 5^{o}C by temperature control chamber for the study of temperature effect. The experimental setup consists of the blue laser and temperature control chamber as shown in Fig. 1. The effects of concentration and temperature on luminescence decay of fluorescent dye can be investigated and the analysis of the spectrum of orange dye at different concentrations and temperatures was carried out using peak fit analysis method.

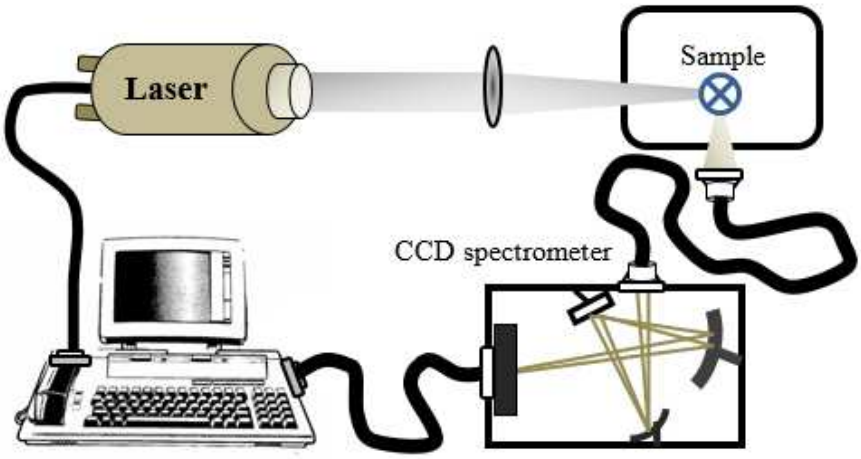

Fig. 1. Schematic diagram of experimental set-up. 470 nm blue laser was utilized as light source. Fluorescence spectra were obtained with the use of a Fiber Optic Spectrometer (model BTC-110S). The system was controlled by a computer.

Results and discussion

When fluorescence dye solutions were excited by the blue laser in the wavelength of 470 nm, the energy was absorbed by the molecule dye. This molecule was excited to exciting state energy level and this energy was transferred to the ground state by the emission at 570-640 nm. The results showed that fluorescence spectra of the orange dye had the same response when the concentration and temperature of the dye solution increased, resulting in a decrease of the maximum emission intensity of the orange dye (Figs. 2-3).The luminescence decays of fluorescence dye decreased as temperature increased. The mechanism of the temperature sensitivity of the fluorescence dye solutions is based on thermal quenching. The effects is a general tendency for fluorescence quantum yields of solute molecules in liquid solutions to decrease slightly with increasing in temperature because non-radiative decay rate increases with increasing temperature [8,9].

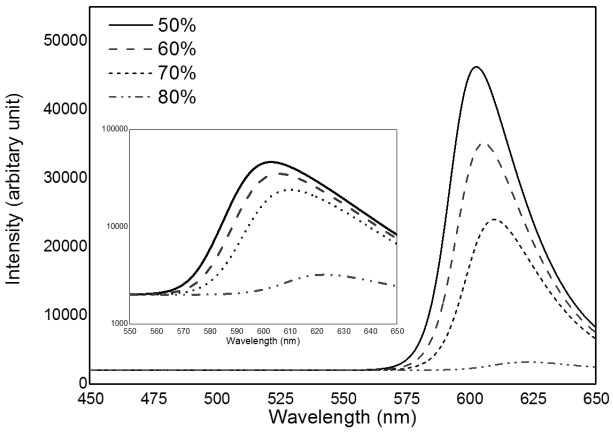

Fig. 2. Relationship between the orange dye wavelength and fluorescence intensity in various concentration at 50, 60, 70 and 80% by volume

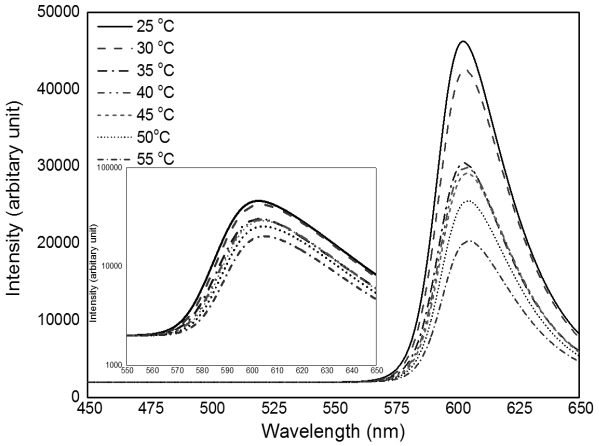

Fig. 3. Relationship between the orange dye wavelength fluorescence intensity at various temperature from 25 to 55°C

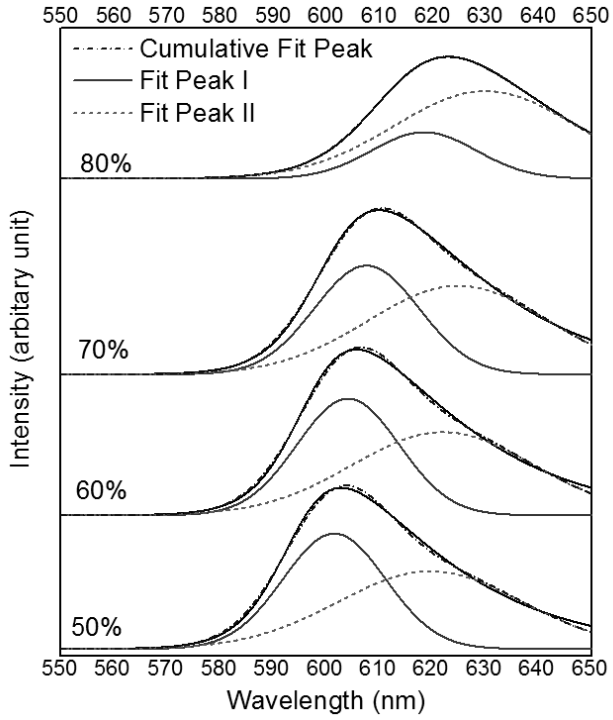

Fig. 4. Effect of concentration on the florescence spectra of the orange dye by using program fit peak analysis

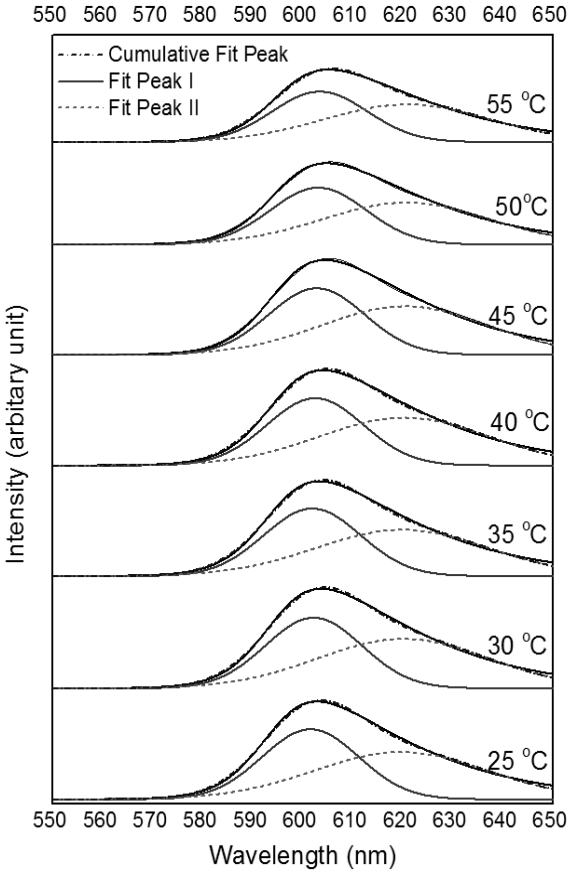

Fig. 5. Effect of temperature on the fluorescence spectra of the orange dye by using program fit peak analysis

The results were analyzed using peak fitting. When the concentration and temperature of the orange dye increased, the fluorescence intensity of the dye was decreased and appearance peak positions was slightly shifted as shown in Figs. 4-5. The appearance of peak positions was slightly shifted from 601.51 to 604.12, 607.64, and 618.44 nm at the concentration of 50, 60, 70, and 80 % by volume respectively as shown in Table 1 (left). The result of interaction between solvent (ethanol) and solute (dye) is probably responsible for the peak shift observed [10]. However, the increase of temperature resulted in only a slight change of peak shift to higher wavelength (Table 1 (right)).

TABLE 1: PEAK FIT ANALYSIS DATA RELATED TO CONCENTRATION AND TEMPERATURE PARAMETERS

Concentration (by volume)	Peak I (nm)	Peak II (nm)
50%	601.51	619.62
60%	604.12	622.01
70%	607.64	624.87
80%	618.44	630.00

Temperature	Peak I (nm)	Peak II (nm)
25°C	601.51	619.62
30°C	601.88	619.88
35°C	602.16	620.06
40°C	602.46	620.27
45°C	602.76	620.41
50°C	603.07	620.63
55°C	603.39	620.87

Conclusions

The results showed that the orange dye gave the same trend of luminescence decay curves for the study of temperature effect and concentration effect. The luminescence decays of fluorescence dye decreased as temperature and concentration increased. In analysis by peak fitting**,** it was found also from the experiment that the peak positions of the luminescence spectra changed with concentration from 601.51 to 604.12, 607.64, and 618.44 nm wavelengths at the concentrations 50, 60, 70, and 80 % by volume, respectively.

Keywords : Steel ; arc welding ; Stress ; X-Ray Diffraction ; microstructures.

Abstract: X-ray diffraction method has been used to analyze the residual stress distribution in weld region of an X70 pipeline steel before and after heat treatment. The welding process has been realized by industrial arc welding with circular weld seams. The effect of heat treatments on the level and the distribution of residual stresses were investigated. Stress distribution was characterized by relative high compressive stresses in weld seam just after welding. However, residual stress relaxation phenomenon was observed in weld region after heat treatments due to microstructure restoration and recrystalization. Optical microscope observation and Vickers hardness measurements were also realized as complementary microstructure characterization techniques.

Introduction

Welding is a process of joining materials into one piece. Welding is one of the most important technological process used in many branches of industry such as industrial engineering, shipbuilding, pipeline fabrication among others. Generally, welding is the prefered joining method and most common steels are weldable.

However, welding is a complicated process accompanied by shrinkage effects, phase transformations, intensification of corrosion and arising of residual stresses. Residual stresses arising after welding exert a considerable influence on the service characteristics of welded equipment and their control allows to avoid failure of welded joint [1].

In arc welding operations residual stresses are introduced within the welded metal owing to the non-uniform tmerature distribution and severe temperature gradients. These residual stresses may be responsible for brittle fracture, decreasing fatigue life as well as stress corrosion cracking [2]. Consequently, it is very important to understand and quantify the residual stresses.

A wide variety of residual stress measurement techniques exist [3-9]. but one of the important is the X-ray diffraction technique. The aim of the present work is to analyze by X-ray diffraction the residual stress development in the heataffected zone (HAZ) of an X70 pipeline steel. This investigation is a contribution as many scientific works which have been done on welding of low carbon steel [10-13]

Experimental procedure

X70 pipeline steel with single-V preparation joint were welded by arc welding (Fig.1).

Fig. 1 X70 pipeline steel after industrial arc welding.

Figure 2 presents the analysis by EDAX of this steel which indicates the high quantity of Mn.

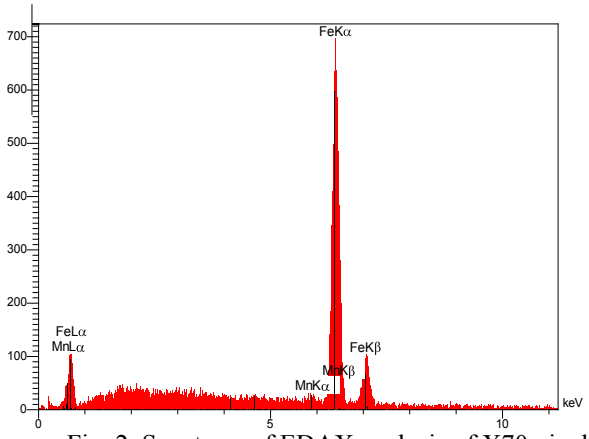

Fig. 2 Spectrum of EDAX analysis of X70 pipeline steel.

The chemical composition of this pipeline steel is given in table 1:

TABLE 1 CHEMICAL COMPOSITION OF PIPELINE STEEL(WT %).

C	Si	Mn	P	S	Cr	Ni	Cu	Al	N	Mo
0.064	0.2047	1.573	0.0154	0.0015	0.0553	0.1922	0.0291	0.0319	0.007	0.1353

The microstructure of this base metal is presented in figure 3. This material is composed of ferrite (85%) with bands of pearlite (15%). The average hardness is 200 HV_{10}. These bands of perlite-rich area (banding) were observed. This macrosegregation phenomenon which called banding is due to the presence of high percentage of Mn in these zones. However, in more alloyed weld metals elements such as chromuim and molybdenum can be found to be segregated in these areas [14].

X-ray stress measurements were carried out by SET-X equipment. A general view of this apparatus is shown on figure 4. Cr-Ka radiation and (211) reflections were used to study residual stress distribution in weld region.

Fig. 4 General view of the X-ray apparatus.

For optical microscopy, chemical etchning was used to reveal microstructures ofdifferent zones. The hardness across the weld was measured by microhardness tester using a 2 kg load. Stress measurements were made in the longitudinal and transversal directions (parallel and perpendicular to the weld joint, respectively). In order to remove residual stresses introduced by machining, an electropoloishing technique has been applied. Optical observation after chemical etchning by Nital of the weld material has revealed the microsstructures of different zones, i.e, weld seam, heat affected zone (HAZ) and base metal. Heat treatments were applied on welded specimens by isothermal annealing at 200 and 600 °C during 1 hour in order to study their effects on residual stresses distribution in X70 pipeline steel.

Results and discussion

In order to have a general idea about the effect of heat treatments on microstructural evolution in weld region of X70 pipeline steel, figure 5 reveals microstructural transformation from non-heated to heated specimen at 600°C in weld seam which represents the core of welding region. This zone submits recrystallization reaction after heat treatments.

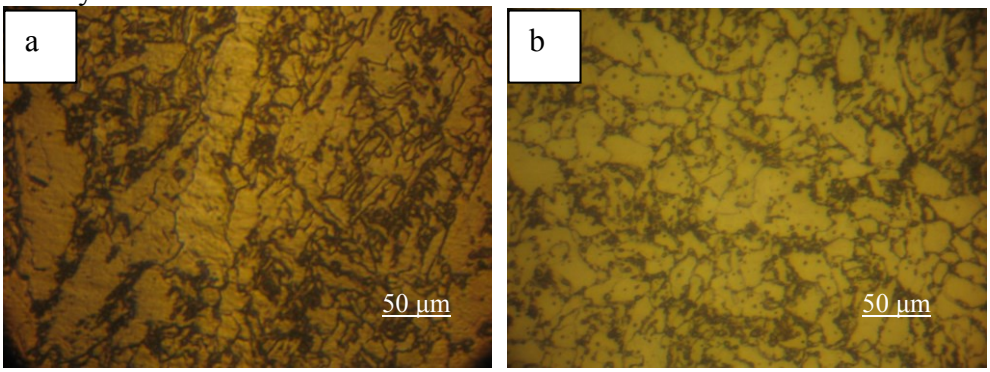

Fig. 5 Microstructures of X70 pipeline steel in weld region:
(a) non-heat treated and (b) heat treated 1h at 600°C.

It was reported that a hardness testing is the usual approach in dilineating the properties of these various zones, but the information obtained is very limited [15]. For other researchers, a simple rapid way to obtain important information is by hardness testing [16]. Concerning our material, the

hardness distribution in different zones is shown in figure 6. The hardness values of 192-214 HV in figure 6 are observed at location within 1 mm from the fusion zone, through the HAZ to the other base metal. Our hardness results are in good agreement with literature. Because, Gul et al [17], have found that maximum hardness values are measured in the area of weld metal (WM). The variation in properties across the weld can be attributed to several factors, mainly to residual stresses just after welding. On the other hand, other factors can contribuate to this hardening like grain size, phase composition, metallic inclusions.

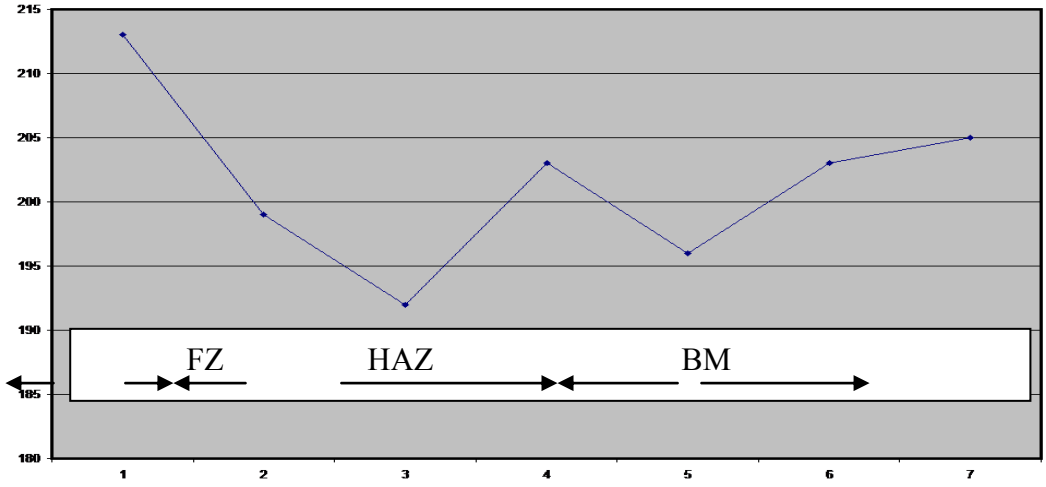

Fig. 6 Microhardness from the fusion zone (FZ) across the weld metal after welding of X70 pipeline steel.

However, figures 7, 8 and 9 present both residual stresses distribution in the weld region of X70 pipeline steel at different states and the peak width evolution in weld region respectively. Concerning the stress distributions, it is clear that all curves have the same shape but not the same magnitude because the the effect of heat treatments is obvious. The magnitude of residual stresses decrease significantly with increasing a temperature.

For example, figure 7 presents the stress distributions in the weld region of X70 pipeline steel. Compressive residual stresses in two directions were observed in weld seam, heat affected zone (HAZ) and base metal. The results indicate that in weld seam the value of stress is -195 in longitudinal direction and – 265 MPa in transversal direction. The maximum of compressive residual stresses are at 2 mm from weld seam (– 265 Mpa and 300 MPa). From 10 mm to weld seam the level of stress becames low compressive in both directions (- 100 MPa). For example, Ranjbarnodeh et al [18] habe been found that when dissimilar metals are joined by fusion process such as TIG welding technique, mixing of the base metals and the filler metal results in the weld region to have different mechanical properties and this phenomenon affects the distribution of residual stress after welding operation.Generally, the predominant cause of welded residual stresses is quenching, because according to Macherauch et al [19] the principal sources of residual stresses after welding are: shrinkage, quenching or phase transformation. Shrinkage causes the appearance of tensile stresses, whereas quenching and phase transformation cause compressive stresses at the weld seam. On the other hand, Prabhat et al [20] considered that the distribution of residual stresses in a girth welded pipe is complex. Weld shrinkage in the circumferential direction induces both shearing and bending that result in stress components in the circumferential direction (hoop stress) and in the axial direction (meridian stress).

However, heat treatments induce a phenomenon of relaxation in the material , because the width peak diminishs with increasing temperature. For example, the heat treated specimen at 200°C, the width peak of diffraction varies from 1,34° to 1,97° which corresponds to high relaxation in all zones (Fig; 8b). The same evolution has been observed in heat treated sample at 600°C (Fig.9). In addition, the level of stresses became nul after the heat treatment at 600°C. There is reasonable agreement between the the stress distributions and width peak of diffraction in weld region.

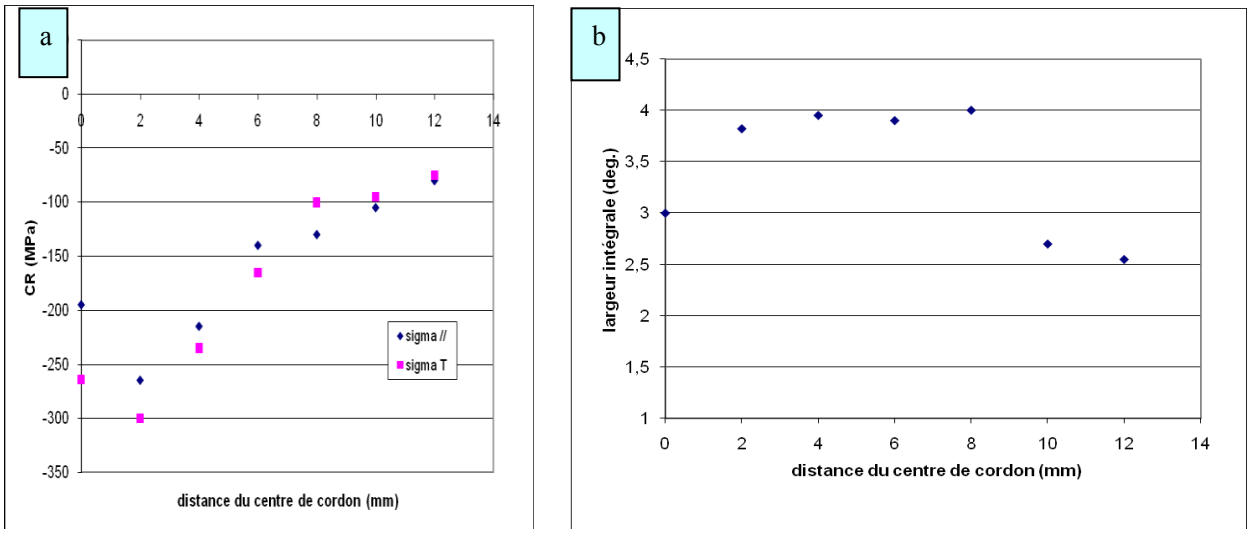

Fig.7 : (a) The stress distributions and (b) width peak evolution in the weld region of X70 pipeline steel

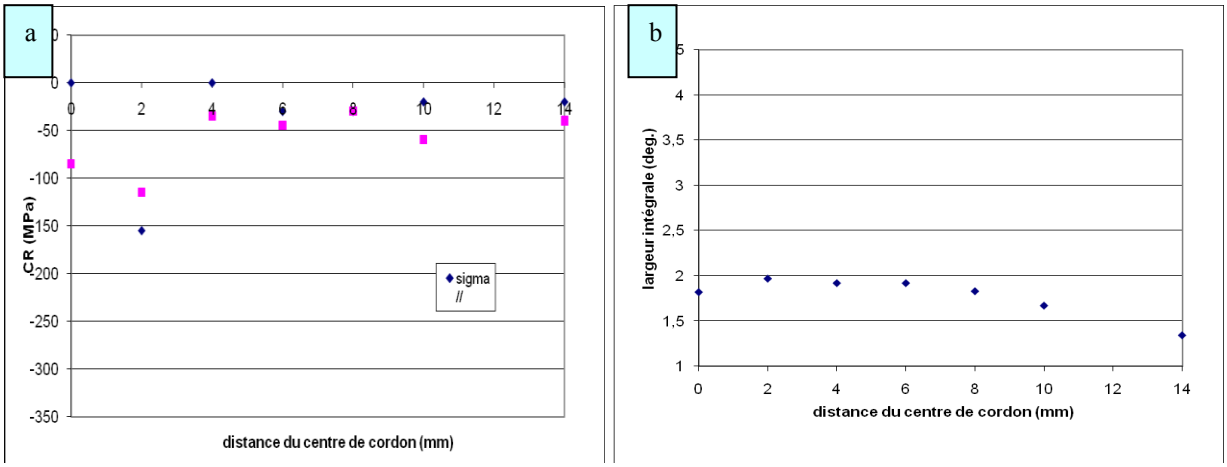

Fig. 8 : (a) The stress distributions and (b) width peak diffraction evolution in the weld region of X70 pipeline steel heat treated 1 h at 200°C.

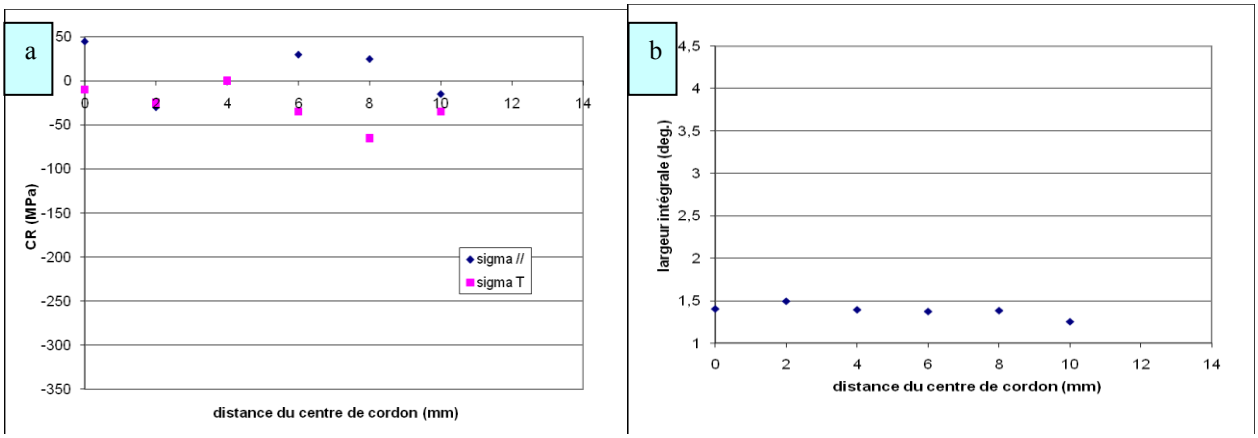

Fig. 9 : The stress distributions and (b) width peak diffraction evolution in the weld region of X70 pipeline steel heat treat 1 h at 600°C.

Conclusion

Our investigation represents a contribution to the study of the distributions of residual stresses on the X70 pipeline steel jointed by industrial arc welding. Stress distribution is characterised by high compressive stresses in weld seam. However, the heat treatments cause relaxation phenomenon in weld region which is due to the recrystalization reaction caused by the heat treatments.

Static Tensile Properties Simulation of Plane Woven-reinforced Laminates with Hole Damage

WEI Wuguo

Aviation Engineering Institute, Civil Aviation Flight University of China, Sichuan Guanghan, 618307, China

weiwuguo@163.com

Keywords: plane woven-reinforced laminates; damage tolerance analysis; 3-D finite element; tensile properties simulation

Abstract: According to the structural difference between the unidirectional and the bidirectional laminate ply, the traditional 3-D (three-dimensional) Hashin failure criteria and the corresponding stiffness degradation rules were amended for damage tolerance simulation analysis of plane woven-reinforced laminates. Based on 3-D finite element technique, a secondary development was carried out on ANSYS software platform, a cumulative damage model was established, and the simulation analysis program for damage tolerance analysis of plane woven-reinforced laminates with hole damage was developed by use of APDL (ANSYS Parametric Design Language). In order to study the influence of different hole diameters on damage tolerance of plane woven-reinforced laminates, two kinds of G803/BMP316 plane woven-reinforced laminates with different hole diameters were selected as the analysis and verification object, and residual tensile strength and damage extension process of the damaged laminates were predicted and analyzed in the simulation. The simulations results are close to the experimental results, and visually present the situation of damage extension in each ply. It provides an effective tool for the damage tolerance analysis of plane woven-reinforced laminates with hole damage.

Forewords

Plane woven-reinforced laminates is one kind of textile composites material, is one kind of composite laminates formed by the combination of plain, twill or satin fabric as reinforced material and resin matrix, and has a widely application in civilian aircraft structure, such as helicopter main blades, tail rotors, et.. In principle, there are repair requirements for all composite structures which applied in engineering field [1]. In the actual operation of civil aircrafts, a variety of damages, for example: hole damage, will be generated inevitably in the composite structures, and there is necessary to repair without delay. But before the repair, damage tolerance analysis for damaged composite structures should be carried out, including residual strength calculation and damage extension analysis. And then, based on the analysis results, the repair tolerance (allowable damage, repairable damage or irreparable damage) of the damaged composite structures should be determined according to flight loads and airworthiness standards. These analyses can reduce the cost of test specimens, shorten the repair cycle and improve the repair design level. For those damage repairs of key parts which unable to test, damage tolerance analysis is particularly important.

Since the 1980s, an advanced composites technology (ACT) project had been launched by NASA. The mechanical properties and test methods of textile composite material had been studied deeply for many years, and a lot of achievements had been summarized. The strength [2-4] and the elastic modulus [5,6] of fabric bidirectional ply had been predicted by use of finite element method on the perspective of mesomechanics in most of existing researches. Compared with the traditional unidirectional ply, the fibers are laying in both warp and weft directions in each ply of plane woven-reinforced laminates. And, warp and weft fibers are interwoven, the interwoven parts of the fibers are slightly bent, lead to some changes on mechanical properties of the fibers itself. So, plane woven-reinforced laminates which laminated by several bidirectional plies in different angles is different from the traditional composite laminates which laminated by several unidirectional plies in different angles on mechanical properties and failure characteristics. The fabric reinforced

composites which applied in helicopter structures had been taken as analysis object by some Chinese researchers [7,8], through the comparison with traditional composite material on mechanical properties and failure characteristics, and based on 2-D (two-dimensional) finite element technique; the damage tolerance of these materials had been analyzed by use of cumulative damage method. But, the influence of interlaminar stress had not been taken into account in the research; there were no delamination failure criteria in the finite element model. And, the influence of different hole diameters on mechanical properties and damage extension process also had not been taken into account.

On the basis of previous studies, a 3-D (three-dimensional) finite element model was established in this paper, which could be applied in damage tolerance analysis of plane woven-reinforced laminates. The delamination failure criteria were added, the stiffness degradation rules were redeveloped, and a material nonlinear factor was introduced in failure criteria. And the simulation program was developed by use of APDL (ANSYS Parametric Design Language) on ANSYS software platform. In order to explore the tensile failure mechanism and study the influence of different hole diameters on damage tolerance of plane woven-reinforced laminates, two kinds of G803/BMP316 plane woven-reinforced laminates with different hole diameters were selected as analysis object. Residual tensile strength and damage extension process of the damaged G803/BMP316 laminates were estimated and analyzed by use of the program, and the analysis results were verified by experiments. Obviously, a feasible method for engineering application for damage tolerance analysis and repair tolerance analysis of damaged composite structures was provided through these analyses.

The Analysis Objects

G803/BMP316 plane woven-reinforced laminates with hole damage was selected as the analysis object in this paper. The reinforced material is satin fabric woven by carbon fibers, and the resin matrix is Polyimide resin. In order to analyze the influence of different damage holes on damage tolerance of plane woven-reinforced laminates, two kinds of laminates with different hole diameters but same material system and same layer way were selected for the simulation analysis and experimental verification. The specimens were prepared according to corresponding national standards. In order to simulate the hole damage, the ϕ5mm and ϕ7mm carbide drills were applied to drill holes on undamaged laminates. The geometrical parameters of specimens are shown in Table 1.

Table 1 Dimension parameters of the analysis objects

Material	Layer way	Number of layers	Physical dimension[mm]			
			Length	Width	Thickness	Hole diameter
G803/BMP316	$[(\pm45)/(0,90)/(\pm45)/(0,90)/(\pm45)]_S$	10	230	25±0.5	2.78	5
		10	230	35±0.5	2.69	7

In addition, the mechanical properties and thickness of G803/BMP316 bidirectional ply are listed in Table 2.

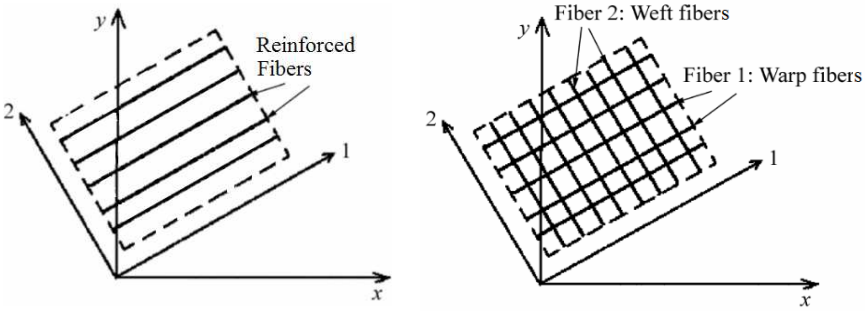
Table 2 Mechanical properties of G803/BMP316 bidirectional ply [9]

Strengths[MPa]						Elastic modulus[GPa]				Poisson's ratio		Thickness of bidirectional ply[mm]
$X_T=Y_T$	$X_C=Y_C$	Z_T	Z_C	S_{12}	$S_{23}=S_{31}$	$E_1=E_2$	E_3	G_{12}	$G_{23}=G_{31}$	μ_{12}	$\mu_{23}=\mu_{31}$	
758.43	380.28	64	185	80.798	39.998	65.208	6.542	4.65	3.725	0.0957	0.0454	0.25

Note: X_T, Y_T, Z_T respectively are tensile strength in direction 1, 2, 3 of bidirectional ply; X_C, Y_C, Z_C respectively are compression strength in direction 1, 2, 3 of bidirectional ply; S_{12}, S_{23}, S_{31} are in-plane shear strength; E_1, E_2, E_3 respectively are tensile modulus in direction 1, 2, 3 of bidirectional ply; G_{12}, G_{23}, G_{31} are in-plane shear modulus; μ_{12}, μ_{23}, μ_{31} are Poisson's ratio.

The Finite Element Simulation Method of Damage Tolerance

The finite element simulation method of composite material gradually accumulated damage, which based on the theory of bidirectional ply, was established in this paper. The damage tolerance of plane woven-reinforced laminates with hole damage could be analyzed by use of the method. There were mainly three problems must to be solved: 3-D finite element modeling and static stress solution; failure determination; stiffness degradation and damage accumulation.



3-D Finite Element Modeling and Static Stress Solution

The static stress analysis of plane woven-reinforced laminates with hole damage was based on 3-D finite element technique. In order to solve the stress accurately, the influence of interlaminar stress must be taken into account. The calculations in theses [10,11] indicate that, there is accurate enough of ANSYS software in the solution of interlaminar stress in composite laminates. So, the software ANSYS10.0 was selected to establish the 3-D finite element model of plane woven-reinforced laminates with hole damage, and to solve the static stress.

A parametric modeling program of damaged laminates with good universality was developed by use of APDL, which could build finite element model of plane woven-reinforced laminates with different hole diameters, layer ways, geometry size or material system. During the simulation in this paper, just the corresponding parameters listed in Table 1 and Table 2 needed to be taken into the program.

Failure Determination

Through the good judgment of strength failure characteristics in direction 1 (fiber direction) and direction 2 (matrix direction) of unidirectional ply, the strength of laminates which laminated by several unidirectional plies at different angles can be well predicted with Hashin failure criteria [12]. But the bidirectional ply in plane woven-reinforced laminates is different from the unidirectional ply on structure, like shown in Figure 1. The mechanical properties of bidirectional ply in direction 1 (warp direction) and direction 2 (weft direction) all are controlled by fibers. So, there is necessary to amend the traditional Hashin failure criteria, and to make it effectively reflect the strength failure characteristics of bidirectional ply.

(a) Unidirectional ply (b) Bidirectional ply

FIG.1 THE DIFFERENCE BETWEEN UNIDIRECTIONAL PLY AND BIDIRECTIONAL PLY

If there is the same percentage of fibers in direction 1 and in direction 2 of bidirectional ply, that means, there are the same strength failure characteristics in direction 1 and in direction 2 of bidirectional ply, then, the Hashin failure criteria can be amended as follows:

(1) Fiber failure criteria in direction 1 (warp direction):

$$\text{Tensile failure } (\sigma_1>0):\ \left(\frac{\sigma_1}{X_T}\right)^2+\left(\frac{\tau_{12}}{S_{12}}\right)^2+\left(\frac{\dfrac{\tau_{31}^2}{2G_{31}}+\dfrac{3}{4}\alpha\tau_{31}^4}{\dfrac{S_{31}^2}{2G_{31}}+\dfrac{3}{4}\alpha S_{31}^4}\right)^2\geq 1 \tag{1}$$

$$\text{Compressive failure } (\sigma_1<0):\ \left(\frac{\sigma_1}{X_C}\right)^2\geq 1 \tag{2}$$

(2) Fiber failure criteria in direction 2 (weft direction):

$$\text{Tensile failure } (\sigma_2>0):\ \left(\frac{\sigma_2}{Y_T}\right)^2+\left(\frac{\tau_{12}}{S_{12}}\right)^2+\left(\frac{\dfrac{\tau_{23}^2}{2G_{23}}+\dfrac{3}{4}\alpha\tau_{23}^4}{\dfrac{S_{23}^2}{2G_{23}}+\dfrac{3}{4}\alpha S_{23}^4}\right)^2\geq 1 \tag{3}$$

$$\text{Compressive failure } (\sigma_2<0):\ \left(\frac{\sigma_2}{Y_C}\right)^2\geq 1 \tag{4}$$

(3) Delamination failure criteria in direction 3 (normal direction):

$$\text{Tensile failure } (\sigma_3 > 0): \left(\frac{\sigma_3}{Z_T}\right)^2 + \left(\frac{\frac{\tau_{31}^2}{2G_{31}} + \frac{3}{4}\alpha\tau_{31}^4}{\frac{S_{31}^2}{2G_{31}} + \frac{3}{4}\alpha S_{31}^4}\right)^2 + \left(\frac{\frac{\tau_{23}^2}{2G_{23}} + \frac{3}{4}\alpha\tau_{23}^4}{\frac{S_{23}^2}{2G_{23}} + \frac{3}{4}\alpha S_{23}^4}\right)^2 \geq 1 \quad (5)$$

$$\text{Compressive failure } (\sigma_3 < 0): \left(\frac{\sigma_3}{Z_C}\right)^2 + \left(\frac{\frac{\tau_{31}^2}{2G_{31}} + \frac{3}{4}\alpha\tau_{31}^4}{\frac{S_{31}^2}{2G_{31}} + \frac{3}{4}\alpha S_{31}^4}\right)^2 + \left(\frac{\frac{\tau_{23}^2}{2G_{23}} + \frac{3}{4}\alpha\tau_{23}^4}{\frac{S_{23}^2}{2G_{23}} + \frac{3}{4}\alpha S_{23}^4}\right)^2 \geq 1 \quad (6)$$

In the formula (1) to (6), σ_1, σ_2, σ_3 respectively are normal stress in direction 1, 2, 3 of the finite element; τ_{12}, τ_{23}, τ_{31} are in-plane shear stress of the finite element; α is the material nonlinearity factor. In failure analysis, as long as one of the inequalities (1) to (6) satisfied by stresses component of one element, then the corresponding failure will be taken place on the element.

Related research in thesis [13] indicates that: the main tensile failure mode of plane woven-reinforced laminates is fiber breakage. The tensile-shear coupling effect on [(±45°)] plies is very small, and the tensile-shear coupling effect on [(0, 90°)] plies basically does not exist. So, the fiber-matrix shear failure criteria were deleted from the amended Hashin criteria.

Stiffness Degradation and Damage Accumulation

If one failure mode taken place on a element in failure analysis, then the mechanical properties of damaged element will be corrected according to the corresponding stiffness degradation rules.

Because there are the same strength failure characteristics in direction 1 and in direction 2 of bidirectional ply, there are the same stiffness degradation rules in direction 1 and in direction 2 of bidirectional ply. And based on the stiffness degradation rules which from theses [14], the new rules could be developed as shown in Table 3:

TABLE 3 STIFFNESS DEGRADATION RULES

No.	Damage forms	Stiffness degradation methods
1	Fiber failure in direction 1	$E_1^*=0.1E_1$; $G_{12}^*=0.1G_{12}$; $G_{31}^*=0.1G_{31}$; $\mu_{12}^*=0.1\mu_{12}$; $\mu_{31}^*=0.1\mu_{31}$;
2	Fiber failure in direction 2	$E_2^*=0.1E_2$; $G_{12}^*=0.1G_{12}$; $G_{23}^*=0.1G_{23}$; $\mu_{12}^*=0.1\mu_{12}$; $\mu_{23}^*=0.1\mu_{23}$;
3	Delamination failure in direction 3	$E_3^*=G_{31}^*=G_{23}^*=\mu_{31}^*=\mu_{23}^*=0$;

Note: E^*, G^*, μ^*, are elastic modulus and Poisson's ratio of damaged element after degradation.

The failure elements gradually accumulate with the increase of load until the laminates can not support. The final destruction criterion of laminates in thesis [15] is: when the elements with fiber failure extended to the edge of laminates along the direction vertical tensile load, the laminates will fracture, cannot support. The rationality of the final destruction criterion was verified by several test results. And, the same final destruction criterion was applied in this paper. That is, for plane woven-reinforced laminates with hole damage, when the elements with fiber failure extended to the edge of laminates along the direction vertical tensile load, the laminates will final fracture.

Analysis Process

According to the failure criteria and stiffness degradation rules, the cumulative damage simulation analysis program was developed by use of APDL on ANSYS software platform, and the specific procedures are as follows:

(1) Determining the size of hole damage and other dimension parameters of damaged laminates according to the actual situation;

(2) Building the 3-D finite element model of the damaged laminates, according to the geometry size of damaged laminates and mechanical properties of bidirectional ply;

(3) Stress solution, and the stress components of each element should be stored in corresponding arrays;

(4) Failure determination of each element according to the amended failure criteria, and stiffness degradation of damaged elements according to the redeveloped stiffness degradation rules;

(5) Increasing load, repeat step (3) and step (4) until the final destruction of laminates, then stop the simulation.

Simulation Results and Experimental Verification

Residual Strength Calculation

The 3-D finite element model of G803/BMP316 laminates with hole damage was established according to the parameters listed in Table 1 and Table 2, and is shown in Figure 2. The boundary conditions are: along the length direction of the model, one end is fixed, and the other end is applied with a tensile load.

The model was meshed with 3-D layered structure 8-nodes solid element SOLID46. In order to analyze the influence of stress concentration in the edge of hole, the edge region of hole was densely meshed by use of grid partial encryption technique. And, in order to analyze the influence of interlaminar stress easily, element thickness was taken as bidirectional ply thickness. According to the above meshing method, the total number of grids of two kinds of laminates models with different hole diameters all are 11200.

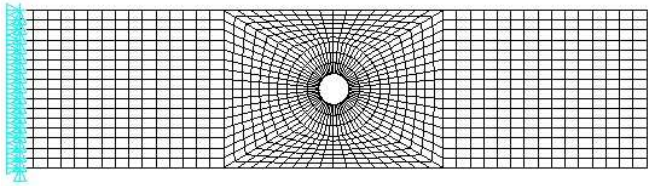


Fig.2 Finite element model of laminates with hole damage

During simulation, the material nonlinearity factor in failure criteria was taken as $\alpha=3.057\times10^{-8}MPa^{-3}$ [16]. And, the calculation results are shown in table 5.

Damage Extension Analysis

The simulation analysis indicates that, there is a same damage extension process of plane woven-reinforced laminates with two kinds of hole diameters under tensile load. So, only the damage extension process of laminates with ϕ5mm hole damage will be analyzed and discussed in this section.

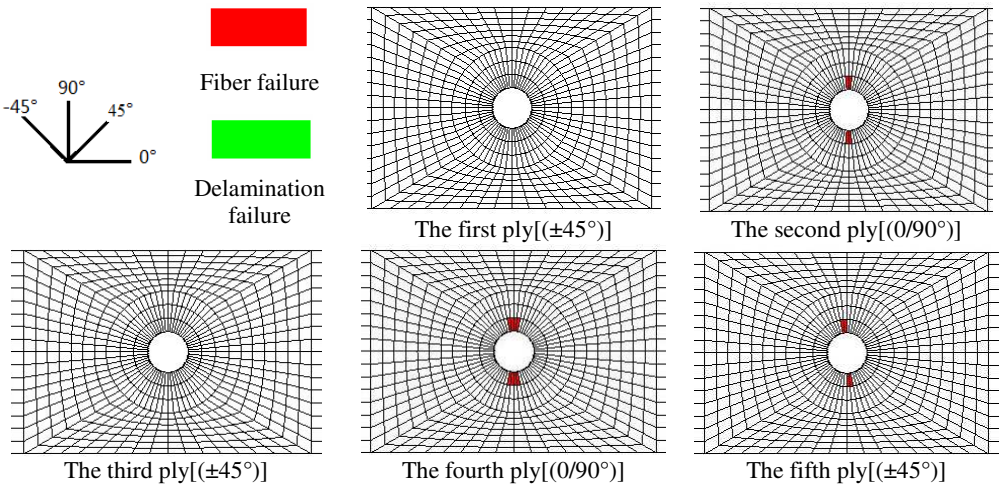

Fig.3 The damage situations of laminates when loading to 325MPa

In the process of simulation, when tensile load is increased to 325MPa, the fiber fracture damage will be found on the second, fourth, fifth, sixth, seventh, ninth ply of laminates model, and all the damages are concentrated in the edge region of hole, as shown in Figure 3. There is no damage found on other plies, and there are no other damage forms only fiber failures. The damage situations of the sixth to the tenth ply are symmetrical with the damage situations of the first to the fifth ply in Figure 3.

With the increase of tensile load, damage quickly extends to other plies, but all of them concentrate in the edge region of hole, and no sign of extension towards the edge of laminates. When the load is increased to 330MPa, damage begins to extend towards the edge of laminates. When the load is increased to 375MPa, eventually damage reaches to the edge of laminates. Then, the laminates model is totally broken, at the same time, the tensile strength of plane woven-reinforced laminates with hole damage is figured out. The damage situations on the first to

the fifth ply of broken laminates are listed in Figure 4, and the damage situations in the sixth to the tenth ply are symmetrical with these failures. Just like the Figure 4, the area and shape of damaged region in each ply of broken laminates are substantially similar, and a little of delamination failures can be found in a few plies.

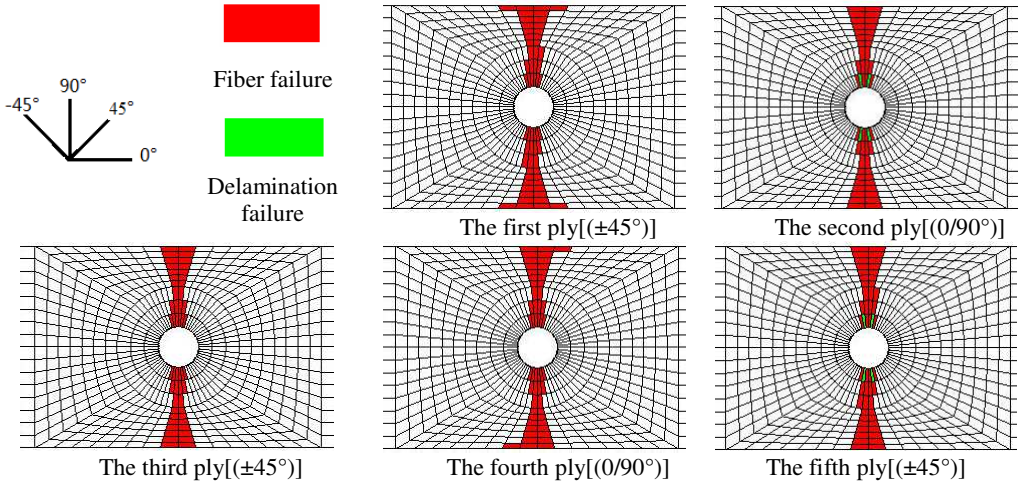

Fig.4 The damage situations of laminates when it finally fractured

Experimental Verification

The specimens for tensile test of plane woven-reinforced laminates with hole damage were prepared according to the size in Table 1. There are five pieces of specimens with ϕ5mm hole, four pieces of specimens with ϕ7mm hole.

Static tensile tests were carried out on WDW-E2000 microcomputer-controlled electronic universal testing machine. The maximum tensile force of testing machine equipped with automatic data acquisition and processing system is up to 200KN, the displacement resolution is 0.01mm, and the test precision is high enough. These tests were carried out in the environment of 18℃ temperature and dry state according to GB/T 3354-1999, and the loading rate was 1mm/min. The test results are shown in Table 4, and the comparison with simulation results is shown in Table 5. The calculated values are close to the experimental values. The maximum error listed in Table 5 is 7.18%, it is enough satisfactory for most engineering applications.

TABLE 4 STATIC TENSILE TEST RESULTS OF G803/BMP316 LAMINATES

Hole Diameter [mm]	Amount of specimens	The average of failure load [KN]	The average of strength [MPa]	Coefficient of Variance of strength [%]
5	5	21.45	387.00	4.79
7	4	29.15	387.84	0.86

Table 5 The comparison of test results and calculated results

Hole diameter [mm]	Strength calculation [MPa]	Strength tests [MPa]	Error [%]
5	375	387.00	3.10
7	360	387.84	7.18

Conclusion

Based on the analysis of mechanical properties and failure characteristics of bidirectional ply, a 3-D finite element model of plane woven-reinforced laminates with hole damage was established, and the simulation program was developed by use of APDL on ANSYS software platform. And then, the damage tolerance of G803/BMP316 laminates with hole damage was analyzed by use of the simulation program and was verified by experiment. The conclusion includes:

(1) The calculated values of residual tensile strength are close to the experimental values. It proves the effectiveness of amended failure criteria and stiffness degradation rules, and provides a convenient engineering approach for damage tolerance analysis of plane woven-reinforced laminates with hole damage.

(2) Most of the failure modes in plane woven-reinforced laminates with hole damage under tensile load are fiber fracture. It is mainly because both direction 1 and direction 2 of bidirectional ply are reinforced by fibers.

(3) There is almost no influence of different hole diameters on mechanical properties and damage extension process of plane woven-reinforced laminates. At first, the damage appears at the edge of hole, with the increase of tensile load, the damage extends mainly along the cross-section stability, rarely along longitudinal.

Keywords: Explosion and shock wave Metal foam material Numerical simulation

Abstract: The goal of this research is to understand the status quo and trend of research on numerical simulation of explosion and shock wave resistance of metal foam material. Methods of modelling metal foam material and numerical algorithms of explosion and shock, as well as the current advances in two aspects have been briefly reviewed. Some problems existing in numerical simualtion of explosion and shock wave resistance of metal foam material have also been pointed out. Conclusions of this research will be of benefit to study explosion and shock wave resistance of metal foam material using numerical approach farther.

Introduction

For excellent cushioning performance and energy-absorption characteristics under blast and impact loading, metal foam has been received extensive attention from research on explosion and shock wave resistance of military vehicle, armed helicopter, naval ship, protective works and so on.

Extensive numerical studies on dynamic mechanical behavior and explosion and shock wave resistance of metal foam have been conducted with the convenience of freely seting analysis conditions in compiled program or general commercial software. The key problem in these numerical simulations is how to characterize this material. There are two ways to solve this problem now. One is to construct solid geometry model with continuous and homogeneous equivalent material for simulating macro dynamic mechanical behavior of metal foam. The other is to construct porous geometry model which has equivalent micro-structural characteristics with matrix material of metal foam to simulate macro dynamic performance and meso structure deformation of metal foam. Moreover, using which kind of numerical algorithms to achieve a better balance between computational accuracy, efficiency and hardware configuration requirements is another important problem which should be taken into account. So, in this paper, this two important problems of numerical simulations on metal foam material have been reviewed.

Characterization Model of Metal Foam Material

Macroscopic Characterization of the Material

The numerical investigation on dynamic behavior of metal foam under blast and impact loading always assumes it as a continuous and homogeneous material except meshless material point method which takes it as noncontinuous material. Macrosc-

poic characterization of metal foam is often adopted, such as: constructing abstract 2D or 3D geometric model of metal foam with no consideration of micro porous structures, only describing macroscopic mechanical behavior of metal foam by using a phenomenological constitutive model and experimental stress-strain curve for metal foam material. The method mentioned above can't investigate the material inhomogeneity, evolution processing of meso structure deformation and its'effect on macro dynamic behavior. When it is accepted in numerical simulation by different researchers, the difference only lies in constitutive model of metal foam material.

Honeycomb Material Model

Honeycomb material model is one of the two typical material models usually applied for characterization of material when the explosion and shock wave resistance of metal foam, such as aluminum foam has been numerical studied by general commercial software such as LS-DYNA, AT-

UO-DYNA, ABQUS etc[1-4]. The major use of this material model is for honeycomb and foam materials with real anisotropic behavior. A nonlinear elastoplastic material behavior can be defined separately for all normal and shear stresses .

Modified honeycomb material model is the improvement of honeycomb material model. The major use of it is for aluminum honeycomb crushable foam materials with anisotropic behavior. Three yield surfaces are available. In the first, nonlinear elastoplastic material behavior can be defined separately for all normal and shear stresses. In the second, a yield surface is defined that considers the effects of off-axis loading. The second yield surface is transversely isotropic. In the third option, the model has been modified so that the user can prescribe the shear and hydrostatic resistance in the material without affecting the uniaxial behavior. For the development of the second and third yield surfaces, the modified honeycomb material model can predict mechanical behavior of honeycomb material more accurately than the honeycomb material model.

Crushable Foam Material Model

Crushable foam material model is another typical material model widely applied for characterization of aluminum foam material in general commercial analysis software[5-8]. This material model can modeling crushable foam with optional damping and tension cutoff. Unloading is fully elastic. Tension is treated as elastic-perfectly-plastic at the tension cut-off value. A modified version of this model , Modified Crushable Foam material model includes strain rate effects.

Other Material Models

In numerical calculation of dynamic behavior of aluminum foam by self-compiling program or otherwise, there are some other elastoplastic models applied for aluminum foam material by some researchers. Ramajeyathilagama K. et al.[9] adopted a elastoplasitc material model with Cowper-Symonds strain rate effect to describe behavior of the aluminum foam material and predicte the deformation and rupture of sandwich plates subjected to underwater shock. A elastoplasitc hydrodynamic model was used for aluminum foam material in LIU's numerical investigation[10]. WANG, et al.[11] accepted a isotropic nolinear material for aluminum foam to simulate explosive resistance and deformation and rupture process of composite steel plate with aluminum foam core. While a linear kinematic hardening material model was used to simulate Constitutive Behaviors of aluminum foam by KANG[12].

Micromechanical Characterization of the Material

Developments of mechanics of porous material and some experiments have indicated that mechanical behavior of metal material could be more accurately and comprehensively predicted by establishing the corresponding relationship between macroscopic mechanical properties and micro structure parameters of metal foam material from the views of micromechanics. As for numerical simulation on this problem, there should be a key reconstruction of micro porous structures of material in numerical model and just a material model of matrix metal of metal foam. There are mainly two reconstruction methods, an approximate theoretical reconstruction method and a experimental characterization method. The approximate theoretical reconstruction is divided into two kinds: reconstruction with periodic micro structures and reconstruction with random irregular micro structures, respectively.

Approximate Theoretical Reconstruction with Periodic Microstructures

Considering micro porous structures, earlier numerical simulations of mechanical behavior of metal foam material always construct a geometry model with periodic distributing cellular micro structures to simplify the real structure of material. Some cellular models such as hollow cubic cell[13-15], tetrakaidecahedral cell[16, 17] are often used(Fig.1). To characterize inhomogeneity of the material, geometric or material parameters of cellular microstructure are assumed fitting a certain statistical distribution.

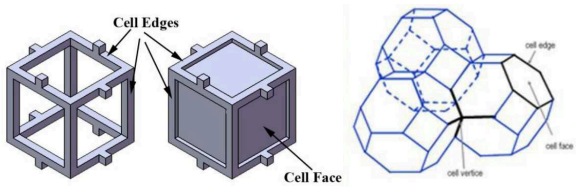

Fig.1 Microstructure model of metal foam(left: cubic cell, right: tetrakaidecahedral cell)

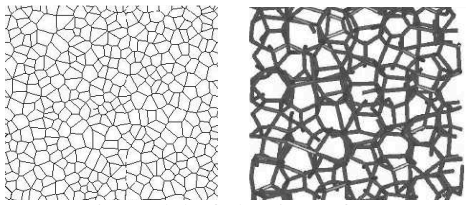

Fig.2 Geometric model of aluminum foam based on voronoi cells (left:2d, right:3d)

Approximate Theoretical Reconstruction with Random and Irregular Microstructures

With improvement of graphic processing ability of computer, finite element analysis of performance of metal foam material by generating geometric model with random microstructures to simulate the real microstructure of material has become a hot research. At present, the dynamic mechanical properties of metal foam are generally numerical calculated with random geometric model based on voronoi spatial distributed algorithm. The voronoi spatial distributed algorithm is a way of dividing space into a number of regions called voronoi cells(Fig.2). The regions are formed by bubbles which grow from each point in a set of points specified beforehand in space.

Finite element simulations of simpler 2d voronoi honeycombs were used by P.J.Tan[18]to illustrate why a greater expenditure of energy accompanied the shock compaction of aluminum foam. The result showed that some macro mechanical performances could be attributed to dynamic deformation in cell edges of 2d voronoi honeycombs. M.Borovinsek, et al. [19] adopted a 3d voronoi lattice model to simulate a open-cell aluminum projectile in Taylor impact test with LS-DYNA. each cell edge of Voronoi model was replaced with three to five beam finite elements of Hughes-Liu type. In order to simulate underwater explosion effects on the deformation behavior of open-cell aluminum foam, M. Vesenjak [20] used 3d voronoi lattice model of aluminum foam to represent the irregularity of the structure. But fluid structure interaction didn't work because of the foam cell edges modeled with beam finite elements in LS-DYNA. For transfering pressure forces to the foam model, a PVC plate was added on the top of aluminum foam and a fluid structure interaction interface was defined between the plate and water.

For limitation of geometry algorithm, 2d voronoi random model can simulate open-cell and close-cell metal foam while 3d voronoi random model can just model open-cell metal foam. In addition voronoi random model embodies randomness of microstructure generating process, but it still can't completely represent inhomogeneity of all mechanical properties of this material.

Another random geometric model carried out by parametric modeling method more easily than that above generally models the closed-cell metal foam material. It consists of a number of hollow spheres (circles for 2d,Fig.3)whose variables including sphere location, size, wall thickness, porosity and number of spheres fit a certain probabilistic distribution in geometry algorithm [21-25].

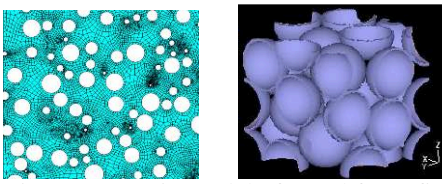

Fig.3 Geometric model of metal foam fitting a probabilistic distribution (left:2d, right:3d)

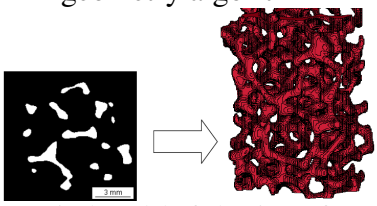

Fig.4 3d numerical model of aluminum foam reconstructed by CT scanning technique

Experimental Reconstruction of Microstructure

Experimental characterization of microstruct-ures of cellular materials reflects characteristics of microstructures of material more accurately than those approximately theoretical reconstructions .Earlier experimental techniques of characterization of microstructure are mainly based on electron microscopy, but only generate two-dimensional image until the focused ion beam technique is applied in forming three-dimensional image.

A better substitute technique has been adopted in recent years [25-27]. It is X-ray microtomography (XRT). The internal microstructures of metal foam material can be imaged by XRT. The 3d numerical model of metal foam material can be reconstructed by the CT scanning pictures of cross sections with certain scanning parameters. Process of reconstruction is as follows: the pictures of cross

sections are replaced with the monochromatic bitmaps. one pixel at the bitmap is assumpted to be the middle layer of one hexagonal finite element in numerical model. A special application that transforms the numbers of pixels into the numbers of finite elements is created. The result of that process is the raster numerical model of an open-cell foam (Fig.4).The experimental reconstruction realistically describes internal structure of metal foam material, but require more resources of computer hardware.

In summary, numerical simulations of mechanical behavior of metal foam material with meso-scale material model mostly focus on quasi static compression, dynamic compact and ballistic impact but a few involve dynamic response of metal foam material under blast loading at present.

Algorithms of Numerical Simulation on Blast and Impact Resistance of Metal Foam Material

Handling capacity for large deformation problem and resolution of different algorithms exist difference in numerical simulation. So it is very important for numerical investigation to select appropriate numerical algorithm. Lagrangian algorithm, Eulerian algorithm, ALE algorithm, et al. can be used to numerically analyze the problem of explosion and shockwave.

Lagrangian Algorithms

Lagrangian algorithms allows an easy tracking of free surfaces and interfaces between different materials but can't follow large distortions of the computational domain without frequent remeshing operations.So it for simulation of blast resistance of aluminum foam material or composite structure filled with aluminum foam will terminate numerical calculateion for mesh large distortion caused by the process of explosion and expansion of detonation products. There are two ways to avoid this phenomenon.

The first one is using lagrangian algorithm to simulate explosion of explosive and interaction between explosion products and structure without air, but manually deleting computational meshes of high explosive model when the contact force between the explosive and structure decreases to nearly zero. This finite element method has been adopted by ZHU[28] in numerical simulation of aluminum foam core sandwich panels with purely Lagrange meshes. Compared with ALE algorithms, this method has the advantage of less calculation time, less computer hardware resources and relatively higher calculating efficiency while has shortcomings of difference between calculating result and actual condition because of omitting air.

The another one is defining blast equations for directly applying blast load to structures without simulation of explosion. For example, to apply blast load to structure in LS-DYNA program, ConWep blast equations is defined. Compared with the first one without considering effects of air, the second method more accurately reflects actual load condition, more simplifies the numerical model, saves more calculating time and hardware resources. So,it has been widely applied in Lagrangian algorithms for simulation of dynamic response of metal foam subjected to blast loading[2, 3, 4, 29].

Arbitrary Lagrangian–Eulerian Algorithms

When the explosion of high explosive and propagation of shock wave should be considered in numerical simulation of blast resistance of metal foam material and composite structure filled with it, the ALE algorithm can be used[5, 7, 8, 10, 20]. To avoid the termination of calculation for large distortion of mesh, the computational meshes of explosive and air medium model are be held fixed but the continuums move with respect to the grids in Eulerian manner. While the computational meshes of metal foam material or composite structure model are be moved in normal Lagrangian fashion to easily tracking deformed surfaces of metal foam material or composite structure.Dynamic data can be transferred with method of fluid-structure coupling among the lagrangian mesh and Eulerian mesh. This ALE algorithms can well cope with explosion of high explosive, propagation of shock wave and large distortion of material or structure in numerical simulation with more resolution than that afforded by a purely Eulerian approach. ALE numerical method can more truly reflect the physical process but at expense of adding complication of numerical model, more calculation time and computing hardware resources. Moreover, the precision of numerical result is dependent on the quality of mesh of numerical model.

Conclusion

How to characterize the metal foam material and which kind of numerical algorithms to be adopted in numerical simulation of blast resistance of metal foam have been discussed in this review. This discussion indicates that numerical simulation has been improved to the level that it can reproduce a truly deformation and failure process of microstructures of metal foam subjected to explosion and shock wave, moreover, can model the whole process of explosion, propagation of shock wave and interaction between shock wave and structure.

Nevertheless, there are still following problems to be solved. Firstly, reconstruction of microstructures of metal foam material whether based on 3d random geometry model or based on CT technique, adds complication and time of numerical calculation and improves the hardware requirements, although more truly describes the internal structures of metal foam. Secondly, numerical simulations of whole physical process of metal foam material under blast loading are still correspondently deficient at present. Thirdly, there isn't a kind of numerical algorithms for simulation can achieve a optimization in truly reflecting of physical process, computational precision, computational efficiency and requirement of hardware resources at the same time.

Keywords: Thermal reactive material, Differential scanning calorimetry, Modelling method, Safety parameter

Abstract: Thermally reactive materials have caused many serious accidents involving storage and transportation, due to being thermally reactive. The safe storage and management of these materials still is a critical problem in many countries. We studied the thermal hazard of thermal reactive materials, such as a propellant, by employing differential scanning calorimetry (DSC) non-isothermal tests and isothermal tests, and then comparing the kinetic parameters by isothermal and non-isothermal of kinetics, avoiding the mistaken results of the single thermal analysis model. The chosen approach was to obtain reliable kinetics of thermal decomposition by safety and effective technology by modelling method, which acquired the safety parameters of storage condition that could be applied as thermal reactive materials' safer design during storage safety conditions and relevant operations.

Introduction

The focus of this study is on the thermal hazard of thermal reactive materials, such as the rifle gun propellant (GP). GP is dangerous and should be transported and stored under limited temperature. In terms of storage and transportation management, many serious explosions and high ambient temperature occur because of thermal decomposition. One reason involves the function group and material of nitrate ester, nitrate, chlorate, perchlorate and phosphorus, etc., due to thermal instability and high sensitivity to spark, light, static electricity, or other energy [1–8].

Here, useing differential scanning calorimetric (DSC) non-isothermal tests and isothermal tests, and then compared the kinetic parameters of GP by isothermal and non-isothermal tests, avoiding the mistaken results of thermal analysis. The chosen approach was to obtain reliable thermal decomposition that included the kinetic parameters, such as the mechanism of thermal decomposition, pre-exponential factor ($\ln k_0$), reaction order (n), activation energy (E_a), and heat of decomposition (ΔH_d) [9–11].

The safety parameters of thermal decomposition for storage conditions include parameters, such as isothermal time to maximum rate (TMR_{iso}), total energy release (TER), and time to conversion limit (TCL) [9–11], and in addition, the thermal hazard properties of thermal reactive materials that could be applied as a reduction of loss prevention for safer design during storage lifetime conditions and relevant operations, which all usefully data will be obtained by modelling method.

Reliable Thermokinetic Parameters Evaluation

Evaluation of kinetic models can involve complex multi-stage reactions that may consist of several independent, parallel, and consecutive stages, demonstrated as Eqs. (1) to (5) [9–11]:

Simple single-stage reaction:

$$\frac{d\alpha}{dt} = k_0 e^{\frac{-E_a}{RT}} f(\alpha) \tag{1}$$

Single-stage for *n*-th order reaction:

$$\frac{d\alpha}{dt} = k_0 e^{\frac{-E_a}{RT}} (1-\alpha)^n \tag{2}$$

Multi-stage for autocatalytic reaction:

$$f(\alpha) = (1-\alpha)^{n_1}(\alpha^{n_2} + z) \tag{3}$$

where E_a is the activation energy, k_0 is the pre-exponential factor, z is the autocatalytic constant, and n_1 and n_2 are the reaction orders of a specific stage.

Reactions that include two consecutive stages:

$$\frac{d\alpha}{dt} = k_1 e^{\frac{-E_1}{RT}} (1-\alpha)^{n_1}; \frac{d\gamma}{dt} = k_2 e^{\frac{-E_2}{RT}} (\alpha-\gamma)^{n_2} \tag{4}$$

where α and γ are the conversions of the reactant A and product C, respectively. E_1 and E_2 are the activation energies of the stages.

Two parallel reactions for full autocatalysis:

$$\frac{d\alpha}{dt} = r_1(\alpha) + r_2(\alpha); \quad \begin{matrix} r_1(\alpha) = k_1(T)(1-\alpha)^{n_1} \\ r_2(\alpha) = k_2(T)\alpha^{n_2}(1-\alpha)^{n_3} \end{matrix} \tag{5}$$

where r_1 and r_2 are the rates of each stage, and n_3 is the reaction order of stage three.

Experimental and Method

GP, which was supplied directly from National Defense University of the Republic of China (ROC) in Taiwan, was stored under 15 °C. The test cell was used to carry out the experiment for withstanding relatively high pressure to approximately 10 MPa. ASTM E698 was used to obtain thermal curves for calculating kinetic parameters. Approximately 0.9–1.1 mg of the sample was used to acquire the GP experimental data. Non-isothermal tests of the scanning rate selected for the programmed temperature ramp were 1, 2, and 4 °C/min. The range of temperature rise chosen was from 30–300 °C for each experiment. Isothermal tests of the holding isothermal condition were several at 175, 180, and 185 °C. The results for the thermal decompositions of GP from the non-isothermal and isothermal of DSC tests are listed in Figs. 1 and 2 & Table 1, respectively.

TABLE 1 RESULTS OF GP DSC TESTS.

Sample mass (mg)	Scanning rate (°C/min)	Peak of Temperature T_p (°C)	ΔH_d (kJ/kg)
1.0	1	181.4	2438
0.9	2	186.3	1655
1.0	4	191.8	2818
Sample mass (mg)	Isothermal conditions (°C)	Maximum heat flow (mW)	ΔH_d (kJ/kg)
1.0	175	2.47	2588
1.0	180	4.93	3201
1.1	185	10.14	1814

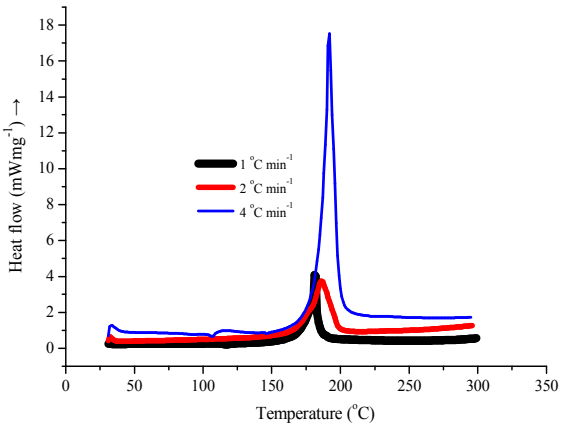

Fig. 1 DSC thermal curves with scanning rate of 1, 2, and 4 °C/min.

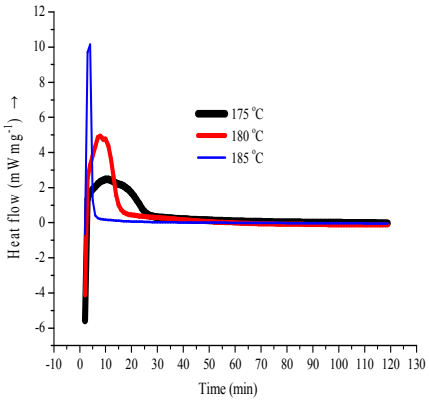

Fig. 2 DSC thermal curves with isothermal temperature at 175, 180 and 185 °C.

Results and Discussion

Determination of Reliable Kinetics by DSC

The thermal decomposition of GP represents an unknown mechanism of reaction, such as an *n*-th order or autocatalytic reaction in this study. Here, using the *n*-th order and autocatalytic simulations to evaluate the thermokinetic parameters and then to compare the results of non-isothermal and isothermal kinetic model simulation, we obtained the mechanism of thermal decomposition for GP. The simulation results are presented in Table 2.

Table 2 show they can be matched very well to the results of the autocatalytic simulations and the *n*-th order simulation for GP, respectively. Clearly, from comparisons of thermokinetic parameters of non-isothermal and isothermal kinetic model simulation, we could observe from the GP kinetic parameters that the mechanism of thermal decomposition belongs to the autocatalytic reaction in this study.

TABLE 2 COMPARISONS OF GP OF THE KINETIC PARAMETERS FOR THE EVALUATION OF *N*-TH ORDER AND AUTOCATALYTIC MODEL SIMULATIONS.

Scanning rate (°C/min)	1		2		4	
Kinetic model	*N*-th order	Autocatalytic	*N*-th order	Autocatalytic	*N*-th order	Autocatalytic
$\ln(k_0)$/ln (1/sec)	60.01	26.04	61.48	24.79	96.17	26.30
E_a (kJ/mol)	249.25	110.97	255.48	113.46	388.59	111.76
Reaction order (n)/nth Reaction order (n_1)/auto	0.57	2.6588	1.14	1.33	1.12	1.96
Reaction order (n_2)	N/A	3.0000	N/A	1.10	N/A	1.83
Autocatalytic constant (z)	N/A	0.0168	N/A	0.08	N/A	0.01
ΔH_d (kJ/kg)	2282.66	2577.39	1733.38	1802.99	2638.97	2770.82
Isothermal temperature (°C)	175		180		185	
Kinetic model	*N*-th order	Autocatalytic	*N*-th order	Autocatalytic	*N*-th order	Autocatalytic
$\ln(k_0)$/ln (1/sec)	27.00	24.61	44.20	24.43	29.60	28.17
E_a (kJ/mol)	127.85	113.04	192.32	110.88	133.86	115.90
Reaction order (n)/nth Reaction order (n_1)/auto	0.14	1.53	0.09	1.80	0.03	2.95
Reaction order (n_2)	N/A	0.65	N/A	0.73	N/A	1.53
Autocatalytic constant (z)	N/A	8.707E-08	N/A	7.051E-06	N/A	3.000E-03

Tables 1 and 2 shows the heat effect of GP at the 2 °C/min scanning rate is smaller than that observed at the other scanning rates. In addition, Tables 1 and 2 also shows the heat effect of GP at holding the isothermal temperature at 185 °C is smaller than that observed at the other isothermal

temperatures. While analyzing the GP's kinetic parameters by simulation, we obtained four values for the autocatalytic thermokinetic parameters by using scanning rates of 1 and 4 °C/min and holding isothermal temperatures under 175 and 180 °C for processing the safety parameters of storage lifetime thermal hazard simulation, respectively.

Storage Lifetime and Safety Parameters Evolution

From above-mentioned results, which were applied to simulate the safety parameters of the thermal decomposition for predicting the TMR_{iso}, TER, and TCL of GP, which can be improved to the actually storage lifetime conditions and relevant operations of thermal reactive materials. The safety parameter assessment of the TMR_{iso}, TER, and TCL of GP was acquired by simulating autocatalytic non-isothermal and isothermal simulation, as displayed in Figs. 3–5.

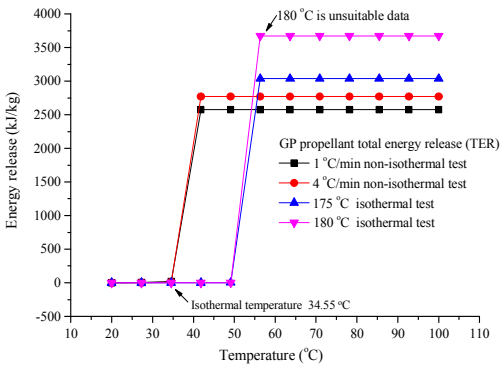

Fig. 3 The storage lifetime and safety parameter assessment of GP total energy release.

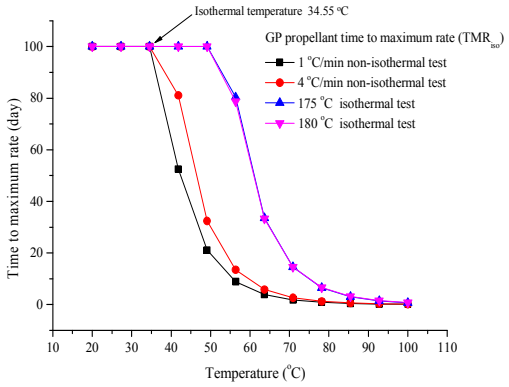

Fig. 4 The storage lifetime and safety parameter assessment of GP time until the maximum rate.

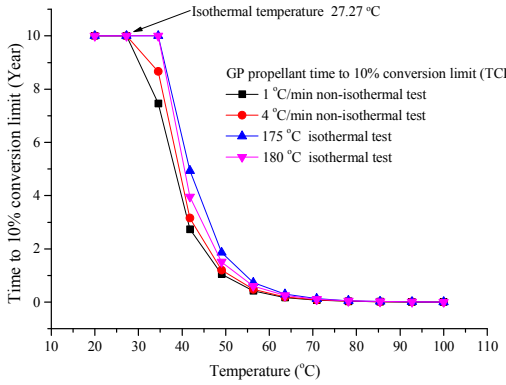

Fig. 5 The storage lifetime and safety parameter assessment of GP time until 10% conversion.

Here, Fig. 3 shows the TER of GP is stored in less than 34.55 °C, and the energy release is under safety condition, and Fig. 4 shows TMR_{iso} of GP obtained, which values were ca. less than 34.55 °C and exceeded the upper limit 100 days. Fig. 5 shows the TCL of GP is less than 27.27 °C, which is beyond the upper limit of 10 years.

Conclusions

These results could be applied toward energy reduction and safer designs for storage of thermal reactive materials. The validity of the results significantly depends on the reliability of the applied kinetic model, which can be confirmed by the proper selection of a kinetic model for a reaction, and the correctness of the modelling methods used for the kinetics and safety parameter evaluation.

Keywords：Brake Disc; Temperature Field; Stress Field; Sequential Coupling Methods; Thermal Fatigue Life

Abstract：This paper analyzed the temperature field of one large mining machinery disc brake during normal braking conditions in ANSYS. Basing on the sequential coupling methods, analyzed the brake disc's thermal stress distribution and changes. According to the analysis results, estimated its thermal fatigue life.

Introduction

Disc brakes are commonly used in large mining machinery. When braking, the huge mechanical energy is almost converted into heat through the interaction of the brake disc and the friction plate except part consumed by the running resistance of the conveyor, which leads to the surface temperature of the brake disk rising sharply, and then causing uneven distribution of the thermal stress. After several brakes, it can lead to thermal fatigue cracking [1]. Therefore, it has important practical engineering significance to the design of the brake disc and to ensure safe operation of the equipment through the temperature and stress fields simulation and thermal fatigue life estimation.

Thermal - structure Coupling Analysis Theory of the Disc Brake[2]

Due to there is no internal heat during braking, and the braking time is short, so the friction heat is mainly redistributed in the form of heat conduction inside the brake disc, and part spreads into the air through the convection heat transfer. In contrast, the proportion of heat radiation is smaller which can be neglected.

Temperature Field Calculation of the Brake Disc

According to the heat transfer theory , the temperature field T satisfies the three-dimensional isotropic transient heat conduction differential equation without internal heat. that is (in the cylindrical coordinate system):

$$\frac{\lambda}{\rho c}\left(\frac{\partial^2 T}{\partial r^2}+\frac{1}{r}\frac{\partial T}{\partial r}+\frac{1}{r^2}\frac{\partial^2 T}{\partial \theta^2}+\frac{\partial^2 T}{\partial z^2}\right)=\frac{\partial T}{\partial t}. \tag{1}$$

In the formula，λ is the thermal conductivity, W/(m·K)；ρ is density, kg/m^3；c is specific heat capacity, J/(kg·K); t is time, s.

Because of the high speed of the brake disc, it causes the convective heat transfer between the ambient air and the brake disc, the heat flux density q of convective heat transfer is:

$$q = h(t_f - t_w) . \tag{2}$$

In the formula, t_f is air temperature(℃); t_w is brake disc surface temperature(℃);h is convective heat transfer coefficient(W/(m^2·K)),changed with the rotational speed, k_a is thermal conductivity of the air, d is the diameter of the friction center, Re is Reynolds Number, $Re=V\rho_a L_c/\mu_a$, V is line speed, ρ_a is air density, L_c is characteristic length, μ_a is air viscosity, then:

$$h = 0.70\left(k_a / d\right)\mathrm{Re}^{0.55} \tag{3}$$

.

Elastic Thermal Stress Calculation

The tremendous friction heat generated during braking lets the temperature distribution in the brake disc uneven, and changing with time, while the brake disc is bound by the supporting shaft and other constraints, so thermal stress is generated. The thermal stress caused by the temperature changing is[3]:

$$\sigma = D(\varepsilon - \varepsilon_0) . \tag{4}$$

σ - stress matrix, MPa; D - elastic matrix, MPa; ε - strain matrix; ε_0 - the initial strain matrix.

Finite Element Model of the Brake Disc

Some related parameters are as follows: Diameter of the brake disc, 2.5m; Disc thickness, 0.1m; Length of the friction plate, 0.36m, Width, 0.25m; Distribution diameter, 2.21m. There are a group of friction plates on both sides of the brake disc, two groups present a 180° distribution. Braking torque and time are respectively 176.8kN·m and 24s, and the initial rotational speed is 60rpm.

Element Selection and Meshing of the Brake Disc

In the temperature field, select the eight node hexahedral elements SOLID70, and use mapped meshing method. In the stress field, convert the SOLID70 elements into SOLID45 elements. The finite element model is shown in Figure 1.

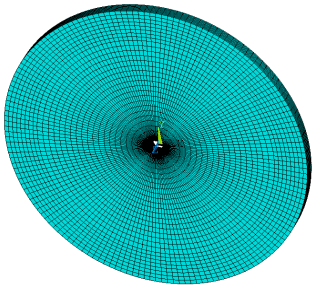

Fig.1Finite Element Model of the Brake Disc

Calculation of Some Relative Data

The material of the brake disc is 16Mn, which density is 7870kg/m^3, poisson ratio is 0.3, the material thermo-physical properties parameters are shown in Table 1[5]:

TABLE 1 THERMO-PHYSICAL PROPERTIES PARAMETERS OF THE BRAKE DISC

temperature [℃]	heat conductivity [W/m·K]	specific heat [J/kg·K]	elasticity modulus [Pa]	coefficient of linear expansion[10^{-6}1/k]
room temperature	53.2	473	2.12E11	0
100	53.2	473	2.08E11	12.8
200	40.9	507	2.03E11	13.4
300	39.4	548	1.97E11	13.9
400	37.8	582	1.85E11	14.5

Assuming that the friction wear between the plate and the brake disc can be neglected, the friction plate clamping pressure in every moment is evenly distributed. According to Fourier's law, heat flux generated by friction $q(r,\theta,t)$ is[6]:

$$q(r,\theta,t) = \mu p(r,\theta,t)\omega(t)r\,. \tag{5}$$

In the formula, μ is friction coefficient, the value is 0.4; p is contact pressure (kN/m^2); ω is angular velocity (rad/s) , assuming the braking is uniform deceleration, in the period of 0 to 24s, the brake disk speed reduced to 0 from 60rpm; r is radius of the brake disc(m).

Temperature Field Analysis under Normal Braking Conditions

In the temperature field analysis, move the thermal load calculated in formula (5) on the friction surface in the form of moving heat.

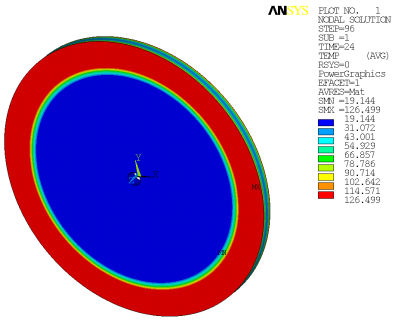

Fig.2 Temperature Contours at the End of Braking

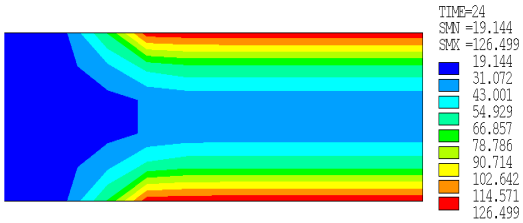

Fig.3 Temperature Contours of a Cross-section

Temperature contours at the end of braking is shown in Figure 2, we can see that along the radial direction , the intermediate region, and along the axial direction, the disc surface ,temperature are all higher . the maximum temperature is 126 ℃ at the end of braking.

Temperature contours of a cross-section at the end of braking is shown in Figure3. the maximum temperature occurs about 0.002m apart from the surface. During the braking, the surface heat not only diffuse from the surface to inside, but also spread into the air through the form of convective heat transfer.

Temperature-time curve of the disc surface in different radius is shown in Figure4. At the beginning of the braking, because of the high rotational speed and huge friction heat, the temperature rises sharply. With braking ,the friction heat decreases, so, after reaching the maximum, the temperature begins to decrease. The temperature of the outermost node is lower than the middle node (r = 1.145m), this is because the outermost node is influenced by the convective heat transfer.

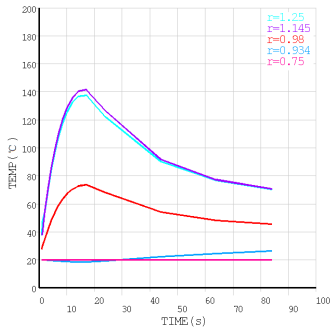

Fig.4 Temp-time Curve in Different Radius

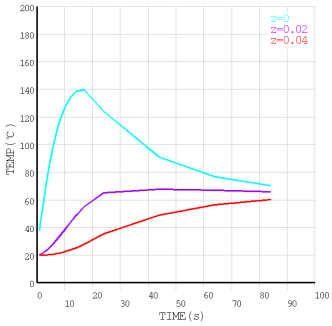

Fig.5 Temp-time Curve at Different Distance from Surface

Figure 5 is the temperature-time curve at different distance(expressed by z)from the surface in the radius of 1.115m. The surface temperature is highest. The farther away from the surface, the lower temperature rise and more smoothly changes. The temperature converged at the end of braking.

Stress Field Simulation Based on the Sequential Coupling Methods

In a braking, the disc experiences alternating heating and cooling cycles. When it brakes more than one time, it will produce thermal fatigue damage. Stress analysis is the gist of the safety assessment and life prediction.

Sequential coupling method, refers to a physical analysis is analyzed in order ,the results of the first physical analysis can be used as the load of the second physical analysis. In this section, we analyze the thermal stress field by using the sequential coupling method. Apply the temperature field analysis results on the stress analysis as body loads, and calculate the brake disc's stress field. Stress contours at the end of braking is shown in Figure 6. The maximum stress is 213MPa.

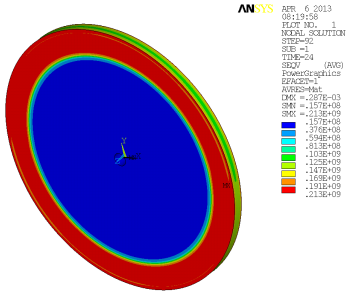

Fig.6 Stress Contours at the End of Braking

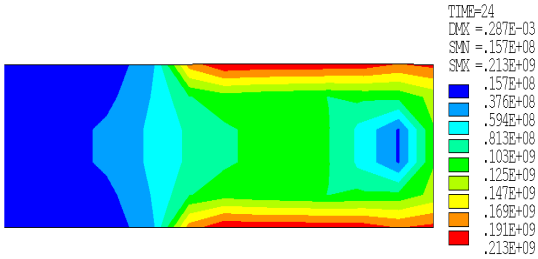

Fig.7 Stress Contours of a Cross-section

Stress contours of a cross-section at the end of braking is shown in Figure 7. The maximum stress occurs in the intermediate region where the brake disc surface contacts with the friction sheet.

Figure 8 is the stress-time curve of the disc node in different radius. With increase of time , the stress value increases firstly and then decreases. The stress curve zigzags during the braking, this is because the alternate function of the input heat and convection heat transfer.

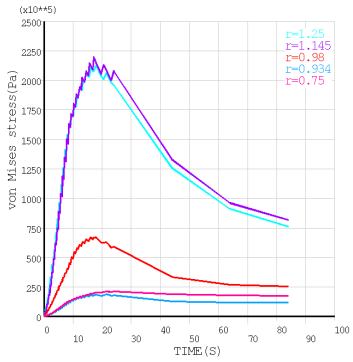

Fig.8 Stress-time Curve in Different Radius.

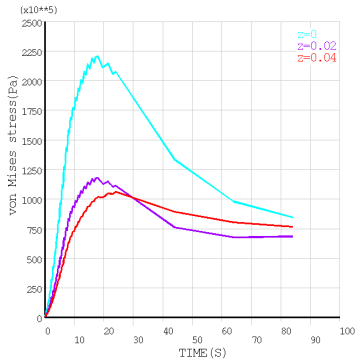

Fig.9Stress-time Curve at Different Distance from Surface.

Figure 9 is the stress-time curve at different distance (expressed by z) from the surface in the radial of 1.115m. The variation of stress in the disc surface is most intense. This is because that the frictional heat can't spread into the inside of the brake disc during the initial period，large amount of frictional heat centered in the surface, so the surface stress rises dramatically.

Thermal Fatigue Life Prediction in Normal Braking Conditions

The brake disc has to endure the alternating load which is shown in Figure 8 in every brake, that is to say the load which the brake disc suffered during its life is unidirectional, unstable and periodic alternating stress，but thinking that the temperature fluctuation is low in one rotation, we can simplify the load to one-way, cyclical and stable alternating stress-pulsating cyclic alternating stress. The minimum stress is 0, and the maximum is 220MPa.

When $N_0 = 10^7$, the pulsation cycle fatigue limit of the 16Mn is 376.4MPa. In accordance with the *S-N* curves, when $N_0 = 10^7$,the survival rate of the sample P=90%, the symmetrical cyclic stress amplitude is, $\sigma_{-1a} = \sigma_{-1\max} = 150$ MPa. The fatigue limit of the structural steel in the pulsation cycle is[7]:

$$\sigma_{0\max} = 1.42\sigma_{-1\max} = 1.42\times 150MPa = 213MPa\,. \tag{6}$$

According to the relevant theories of finite life fatigue calculation, we can estimate the thermal fatigue life N of the brake disc in the normal conditions[8]:

$$\sigma_{0N} = \sigma_0 \sqrt[m]{\frac{N_0}{N}}\,. \tag{7}$$

Material constants m is the negative slope of the *S-N* curve in logarithmic coordinates, that is:

$$m = -\frac{\lg N_0}{\lg \sigma_{0\max}}\,. \tag{8}$$

Hereby, we get the number of braking cycles during its life is: N=5.008×10^7.

Conclusions

This paper analyzes the temperature field of one large mining machinery disc brake during its normal braking conditions in ANSYS. Basing on the sequential coupling methods, we analyze the thermal stress distribution and changes inside the brake disc. The results show that, due to the friction heat, the temperature rises in the braking, and the distribution is uneven, which caused the pulsating cyclic thermal stress during its lifetime. According to the thermal and stress analysis results, we study the thermal fatigue life estimation method, and estimate the brake disc's thermal fatigue life. The simulation methods and analysis results have important reference value and engineering significance to the design and safe operation of the brake disc.

Keywords: the composite cylinder, metal liner, thermal-mechanical coupling mechanism, finite element method

Abstract: As to the composite cylinder with metal liner under the high temperature and high pressure, thermal-mechanical coupling mechanism and response are studied. On the basis of equations for coupling thermal and mechanical impact load and the non-linear thermoelastic finite element equations, the 3-D analysis model of the composite cylinder is established by using the finite element method. The direct coupling analysis is conducted and the variation regularity of the dynamic stress field is obtained. The results show that the thermal-mechanical impact loads can cause large transient stress, which influences the strength of the metal liner obviously.

Introduction

Metal fiber-reinforced liner structure is a common structure among all the composite cylinders in the engineering field such as pressure vessels, compressors, high pressure pipes, barrels and so on. These structures often work subjected to pressure and temperature loads simultaneously. In some special situations, they are even under transient high pressure and high temperature impact. The most typical one is the composite material cylinder which withstands pressure load more than a few hundred MPa and heat shock more than a thousand degrees within several millisecond during the launch of the gun.

This complex loading condition often results in damage and destruction to the structure of composite material cylinders with metal liner, thus, the relation of coupling mechanism of thermal-mechanical load is very important for the research on damage and destruction of the composite cylindrical structures. Several works have been done by scholars at home and abroad on this topic. Kollár [1] gave a solution of a dynamic response model of fiber-reinforced composite material cylinder withstanding variable mechanical and thermal loads which assumes the material is elastic. Brischetto etal [2] analyzed the coupling effects of composite laminated plates on thermal-mechanical aspect. Considering the hot and humid conditions, Jacquemin et al [3] established a semi-analytical model to calculate the stress field under the internal pressure loads. Mei et al [4]conducted theoretical modeling analysis on the carbon fiber composite materials under the thermal-mechanical cyclic loading, moreover, analytical solutions and experimental values were compared; Adopting the two methods of three-dimensional photoelastic experimental stress analysis and finite element calculation ,Zhao Yanru et al [5] did some research on the interfacial shear stress of a three dimensional freezing slice of single-fiber pullout resin matrix composites under the combined effect of pullout loading and thermal residual stress. Based on microscopic damage

mechanism, Wang Fang et al[6] studied the fatigue life of metal matrix composites under the thermal-mechanical cyclic loading. Few research is on thermal-mechanical shock load in all these studies. This paper focuses on the coupling mechanism and response of thermal- mechanical load for composite material cylinder with metal liner.

Basic equations for coupling thermal and mechanical impact load

The composite material cylinder with metal liner is a kind of special structure which works under extreme conditions and is subjected to strong thermal shock and pressure load. The basic equations of thermal structure coupling problem include heat conduction equation of structural deformation and thermoelastic equation considering the effect of inertia.

Without considering the impact of structural deformation on heat transfer, based on the first law of thermodynamics, the heat conduction fundamental equation of structure can be expressed as ,

$$Q\mathrm{d}t = \mathrm{d}U \,. \tag{1}$$

Where, Q is the heat absorbed per unit time, U is the internal energy .

Considering the impact of structure strain on the thermal conductivity , the first law of thermodynamics is expressed as

$$Q\mathrm{d}t = \mathrm{d}U - (\sigma_x \mathrm{d}\varepsilon_x + \sigma_y \mathrm{d}\varepsilon_y + \sigma_z \mathrm{d}\varepsilon_z) \,. \tag{2}$$

Where, $\sigma_x \mathrm{d}\varepsilon_x + \sigma_y \mathrm{d}\varepsilon_y + \sigma_z \mathrm{d}\varepsilon_z$ is the work of mechanical force to the strain.

According to the relationship of thermodynamics and heat transfer theory, the heat conduction fundamental equation can be derived as

$$\frac{\partial}{\partial x}\left(k_x \frac{\partial \phi}{\partial x}\right)+\frac{\partial}{\partial y}\left(k_y \frac{\partial \phi}{\partial y}\right)+\frac{\partial}{\partial z}\left(k_z \frac{\partial \phi}{\partial z}\right)+\rho Q-\beta\phi_0 \frac{\partial e}{\partial t}=\rho c \frac{\partial \phi}{\partial t} \,. \tag{3}$$

Where, ϕ_0 is the initial temperature, $e = \varepsilon_x + \varepsilon_y + \varepsilon_z$ is the total strain, β is the coefficient of thermal stress.

In which $\beta\phi_0 \dfrac{\partial e}{\partial t}$ is the coupling term describing the relation of the structure and thermal, which performs in the form of strain rate. Thus, it is significant on high-speed deformation.

According to the thermo-elastictheory,we can propose the motion equations, geometric equations and physical equations considering the effect of the temperature. The fundamental equations based on displacement method follows:

$$\left.\begin{aligned}
(\lambda+G)\frac{\partial e}{\partial x}+G\nabla^2 u-\beta\frac{\partial \phi}{\partial x}+X=\rho\frac{\partial^2 u}{\partial t^2}\\
(\lambda+G)\frac{\partial e}{\partial y}+G\nabla^2 v-\beta\frac{\partial \phi}{\partial y}+Y=\rho\frac{\partial^2 v}{\partial t^2}\\
(\lambda+G)\frac{\partial e}{\partial z}+G\nabla^2 w-\beta\frac{\partial \phi}{\partial z}+Z=\rho\frac{\partial^2 w}{\partial t^2}
\end{aligned}\right\} . \tag{4}$$

where, λ and G are lame coefficients.

When we solve the coupled thermo-elastic problems by using direct coupling method, we must solve heat conduction Eq.1 and thermo-elastic fundamental Eq.4 simultaneously. Compared with non-coupled thermo-elastic problem, we must consider the impact of thermal conductivity coupling term and thermo-elastic inertia term for coupled dynamic problems.

The non-linear thermoelastic finite element equations

Composite material cylinder with metal liner withstands transient thermal shock and its temperature changes fairly severely. The elastic constants and thermal parameters of metal material and composite material will change as the temperature changes, which makes the thermal conductivity, heat capacity matrix and elastic matrix in finite element equation all relative with Temperature ϕ .Thus the finite element exhibits a temperature-related material nonlinearity.

Therefore, in the transient heat conduction, the temperature recursive format become

$$\left(\boldsymbol{K}(\phi^*)+\frac{\boldsymbol{C}(\phi^*)}{\Delta t}\right)\phi_{n+1}=\boldsymbol{P}(\phi^*)+\frac{\boldsymbol{C}(\phi^*)}{\Delta t}\phi_n . \tag{5}$$

Where $\phi^*=\phi-\phi_0$ is the temperature change for a moment, ϕ_0 is the reference initial temperature. The corresponding thermal strain caused by the change of temperature i.e.

$$\boldsymbol{\varepsilon}_0=\boldsymbol{\alpha}(\phi^*)(\phi-\phi_0) . \tag{6}$$

Meanwhile, the elastic matrix D in the stress-strain relationship $\boldsymbol{\sigma}=\boldsymbol{D}(\boldsymbol{\varepsilon}-\boldsymbol{\varepsilon}_0)$ is also variable because the elastic modulus and poisson's ratio both change with temperature:

$$\begin{aligned} E&=E(\phi^*)\\ \nu&=\nu(\phi^*) \end{aligned} . \tag{7}$$

Therefore, for composite anisotropic material

$$\boldsymbol{D}=\begin{bmatrix} C_{11}(\phi^*) & C_{12}(\phi^*) & C_{13}(\phi^*) & 0 & 0 & 0\\ C_{12}(\phi^*) & C_{22}(\phi^*) & C_{23}(\phi^*) & 0 & 0 & 0\\ C_{13}(\phi^*) & C_{23}(\phi^*) & C_{33}(\phi^*) & 0 & 0 & 0\\ 0 & 0 & 0 & C_{44}(\phi^*) & 0 & 0\\ 0 & 0 & 0 & 0 & C_{55}(\phi^*) & 0\\ 0 & 0 & 0 & 0 & 0 & C_{66}(\phi^*) \end{bmatrix} . \tag{8}$$

Where,

$$
\begin{aligned}
&C_{11} = (1-\upsilon_{23}\upsilon_{32})VE_1 \\
&C_{22} = C_{33} = (1-\upsilon_{12}\upsilon_{21})VE_2 \\
&C_{12} = C_{13} = \upsilon_{21}(1+\upsilon_{23})VE_2 \\
&C_{23} = (\upsilon_{23}+\upsilon_{21}\upsilon_{12})VE_2 \\
&C_{44} = G_{23} = \frac{(1-\upsilon_{23}-2\upsilon_{21}\upsilon_{12})VE_2}{2} \cdot \\
&C_{55} = C_{66} = G_{12} = E_6 \\
&V = \frac{1}{(1+\upsilon_{23})(1-\upsilon_{23}-2\upsilon_{21}\upsilon_{12})}
\end{aligned}
\tag{9}
$$

All parameters are relative with elastic parameters $E_1(\phi^*), E_2(\phi^*)$, $G_{12}(\phi^*), \nu_{12}(\phi^*), \nu_{21}(\phi^*)$ and $\nu_{23}(\phi^*)$ of unidirectional composites. Thus, they are all expressed as the expressions of temperature ϕ^*, for isotropic material,

$$
\boldsymbol{D} = \frac{E(\phi^*)(1-\nu(\phi^*))}{(1+\nu(\phi^*))(1-2\nu(\phi^*))}
\begin{bmatrix}
1 & \frac{\nu(\phi^*)}{1-\nu(\phi^*)} & \frac{\nu(\phi^*)}{1-\nu(\phi^*)} & 0 & 0 & 0 \\
\frac{\nu(\phi^*)}{1-\nu(\phi^*)} & 1 & \frac{\nu(\phi^*)}{1-\nu(\phi^*)} & 0 & 0 & 0 \\
\frac{\nu(\phi^*)}{1-\nu(\phi^*)} & \frac{\nu(\phi^*)}{1-\nu(\phi^*)} & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & \frac{1-2\nu(\phi^*)}{2(1-\nu(\phi^*))} & 0 & 0 \\
0 & 0 & 0 & 0 & \frac{1-2\nu(\phi^*)}{2(1-\nu(\phi^*))} & 0 \\
0 & 0 & 0 & 0 & 0 & \frac{1-2\nu(\phi^*)}{2(1-\nu(\phi^*))}
\end{bmatrix}.
\tag{10}
$$

So, finite element equation is

$$
\boldsymbol{K}(\phi^*)\boldsymbol{a} = \boldsymbol{P}(\phi^*) . \tag{11}
$$

From the Eq.(5~11),we can see that the finite element equation for thermal shock problem of composite material with metal liner is relative with the temperature ϕ.It is a material nonlinear problem with temperature effect which is independent of the time.

The FEM model of the composite material cylinder with metal liner

The nonlinear finite element method(FEM) is used to investigate the response of the composite material cylinder with metal liner under the transient thermal-mechanical impact load.

The geometry construction is shown in Fig.1. It is a complex structure where there are three layers of composite material ($90^\circ/\pm\alpha^\circ/0^\circ$) outside the metal liner locally.

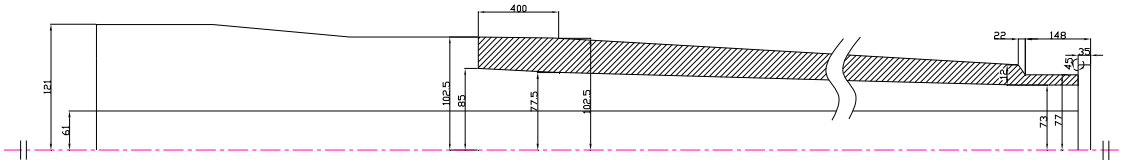

Fig.1 The geometry construction of composite material cylinder with metal liner

The material parameters are shown in Table 1 and 2

TABLE 1 MATERIAL PARAMETERS OF METAL LINER（PCRNI3MO）

E1 [MPa]	υ	σs [MPa]	ρ [Kg·m-3]
210000	0.27	850	7800

TABLE 2 MATERIAL PARAMETERS OF COMPOSITE MATERIAL(T300/EPOXY)

E1 [MPa]	E2 [MPa]	G12 [MPa]	υ12	υ32	ρ [Kg·m-3]	Xt [MPa]	Xc [MPa]	Yt [MPa]	Yc [MPa]	S [MPa]
181000	10300	7170	0.28	0.5	1600	1500	1500	40	246	68

Three-dimensional thermal structure coupled element with 20 nodes is used to mesh the FEM model. The FEM mesh model is as shown in Fig.2.

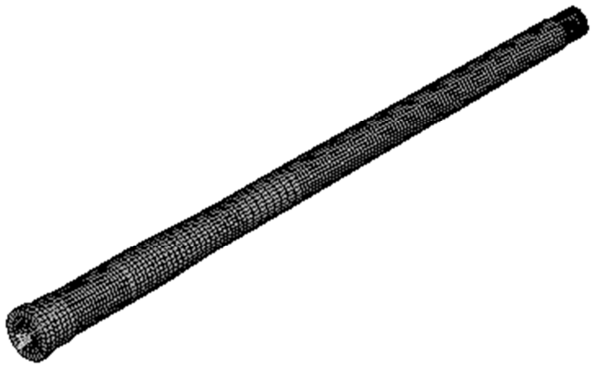

Fig.2 FEM mesh model of the composite material cylinder with metal liner

The loads of the FEM model are thermal shock load and mechanical impact load. They are the high temperature airflow and transient pressure which acted on the inner surface of the hollow cylinder, respectively. In Fig.3, we can easily get the airflow temperature loads curves in different positions. Fig.4 shows the variation range of pressure in the hollow cylinder. The different curves in the figure represent the data of the axis position Z which are from the bottom of the cylinder.

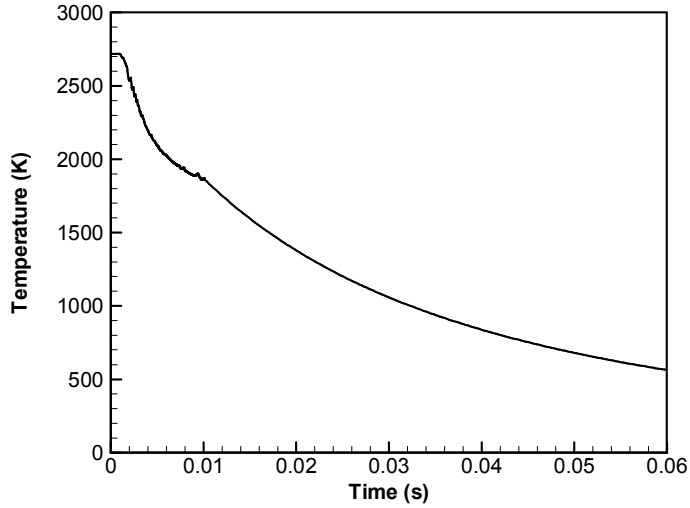

Fig.3 Temperature loads

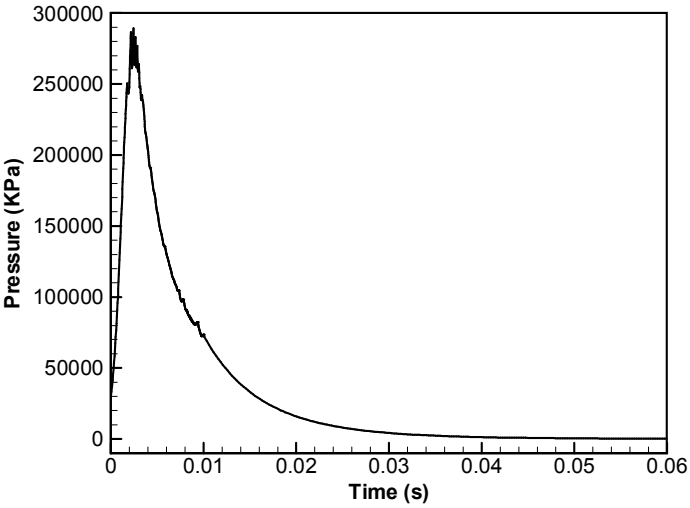

Fig.4 Pressure loads

Result and Analysis

Based on the finite element model, coupling analysis for a three-dimensional composite cylinder subjected to transient thermal-mechanical shock is made by using the direct coupling method which can study the heat conduction equation and stress in the same finite element model. To analyze the thermo-mechanical coupling effects conveniently, two cases are presented. i.e. considering the effect of temperature and without considering the effect of the temperature (only the effect of the pressure is considered). They are presented by the solid and broken lines in the Fig. 5 and Fig.6 respectively.

The equivalent Vonmises stress of the inner wall

The equivalent Vonmises stresses of the inner wall of cylinder are given in Fig.5 and Fig.6. As the figures show that the equivalent Vonmises stress of the inner wall which considers the thermal stress is significantly larger than the one which considers the pressure only, especially for the composite parts . As the poor thermal conductivity of the composite material, a large internal temperature gradients are caused. Thus, the effect of thermal stress must be also considered during the design process as it plays a leading role in the coupled thermal environment.

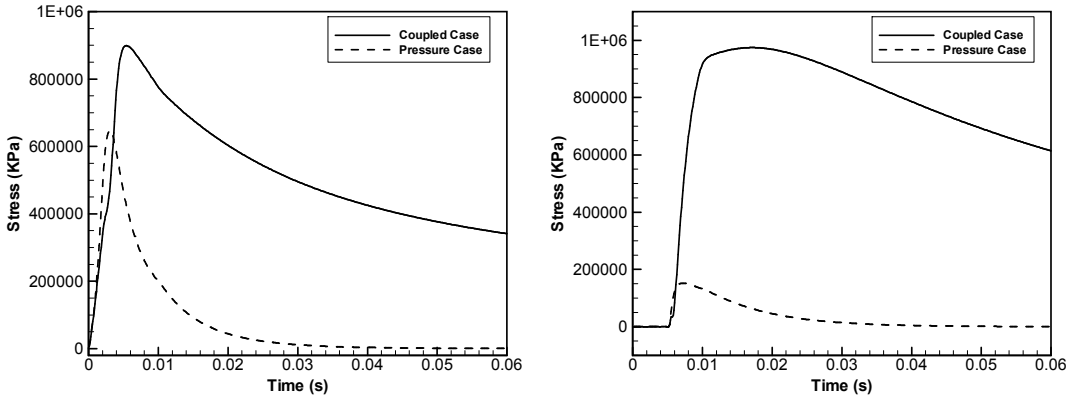

Fig.5 Equivalent Vonmises stress of the inner wall of the metal parts

Fig.6 Equivalent Vonmises stress of the inner wall of the composite parts

The stress of composite part

Fig.7 and Fig. 8 show the radial stress of inner wall and the metal/composite at the interface of the cylindrical composite structure. As we can see from the Fig.7 that the radial stress caused by the pressure is smaller. The radial stress of the metal inner wall is affected by the thermal stress. The three curves are basically the same in Fig.8 as temperature load is transient and the heat has not been conducted only a higher temperature in the wall, thereby causing a higher temperature gradient to a large thermal stress. The same conclusion can be obtained from the result of circumferential stress and axial stress.

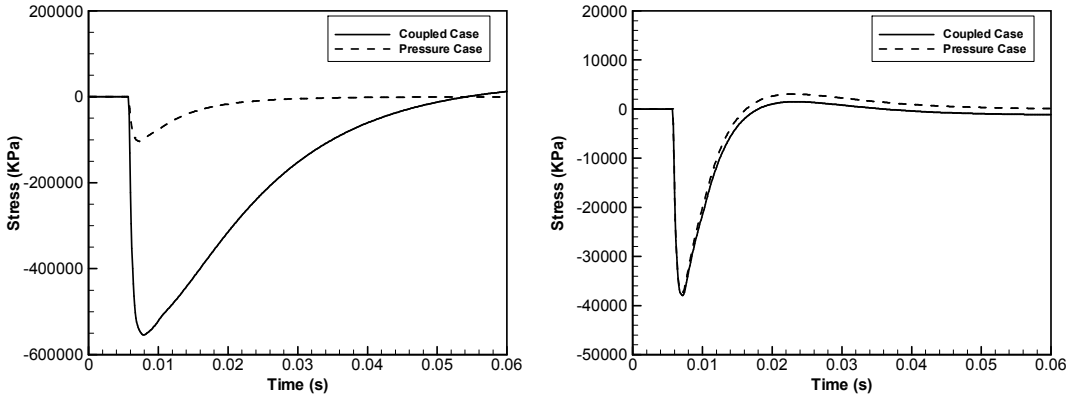

Figure 7 Radial stress of inner wall of metal lining layer

Figure 8 Radial stress of Interface (metal part and composite part)

The results of the circumferential stress are given in Fig. 9 and Fig.10. From the Fig.9, we can find that the circumferential stress is positive in the inner wall of the metal layer lining. While taking into account the effect of temperature, a large stress in the wall as the thermal stress is existed caused by high temperature in the inner wall and the temperature of outer wall is small. With the combined effect of the pressure, the compressive stress caused by heat is large than the tensile stress caused by the pressure. Therefore, it is negative. Fig.10 and Fig.11 shows that the circumferential stress is not affected by temperature for the gradient of temperature is small in the composite material layer. Moreover, the circumferential stress of the metal part and the composite material is not the same since that it must satisfy the continuous strain assumptions in the interface layer between two different materials. Due to the different elastic moduli of the material, the result obtained is no longer equal. The situation exists in the axial stress.

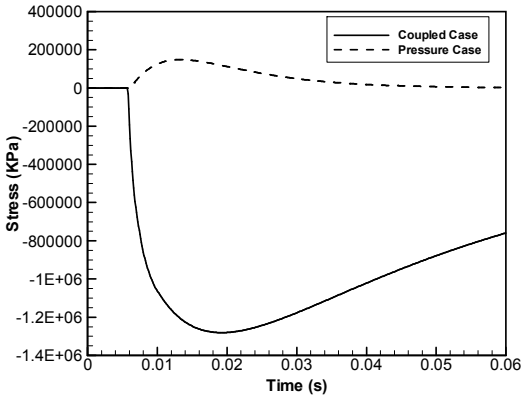

Figure 9 Circumferential stress of inner of metal lining layer

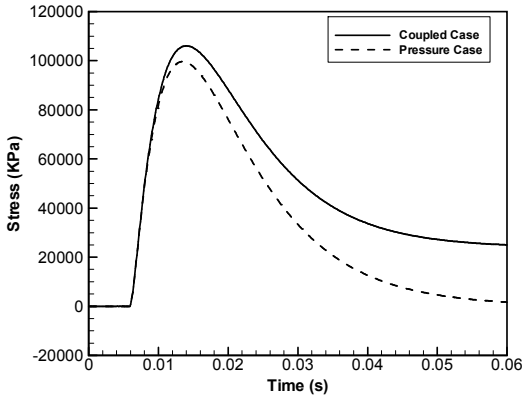

Figure 10 Circumferential stress of Interface wall (metal part)

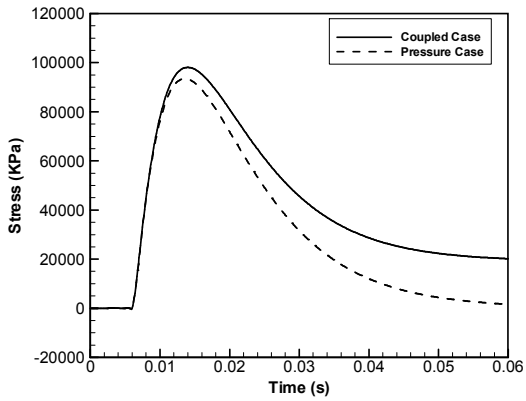

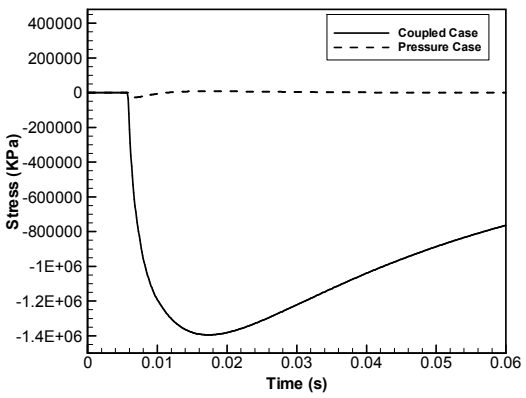

Figure 11 Circumferential stress of Interface (composite part)

The results of the axis stress are given in Figure 12, Figure 13 and Figure 14. The similar conclusion can be obtained through the curves of the axis stress that thermal stress caused by gradient of temperature has a greater contribution to the stress in the inner wall. While in the composite layer, stress doesn't change significantly for the gradient of temperature is small.

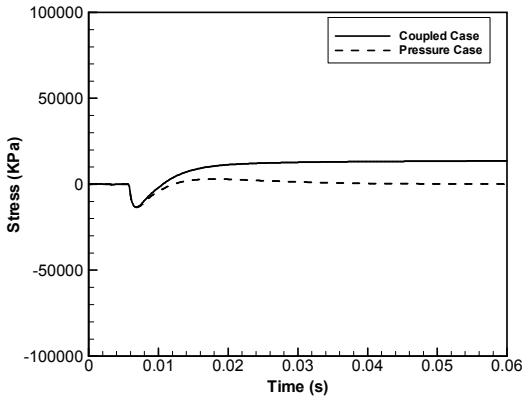

Figure 12 Axial stress of inner wall of metal lining layer

Figure 13 Axial stress of Interface（metal part）

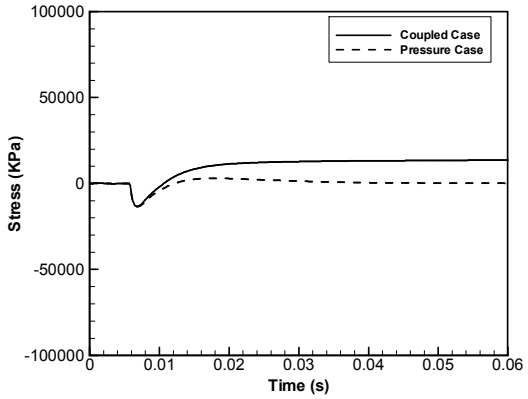

Figure 14 Axial stress of Interface (composite part)

Conclusion

The response of the composite cylinder with metal liner is studied under the thermal-mechanical impact loads by using FEM. The results show that thermal stress can not be ignored as the temperature of the inner wall change fast causing large gradient of temperature. Especially for the composite part, it is more significant because of the poor thermal conductivity of the composite material. Therefore, it should be possible to improve the thermal performance of the composite material and keep the performance of structure when designing the composite structure of the cylinder. For example, adding metal powder or other thermally conductive material in the composite material resin matrix.

Keywords: microwave regeneration, porous composite, diesel particulate filter

Abstract:In this study, porous SiO_2·RO/stainless steel composite body was prepared through the polyurethane sponge replica method. Porous samples obtained through sintering consist of well dispersed and distributed stainless steel particles within the glass matrix. Such microstructure is desired for the purpose as a soot particulate filters (DPF) utilizing microwave rapid and selective heating characteristic, especially during the cold start phase of an engine. Results of microwave heating ability and diesel soot regeneration tests shows that, the fabricated porous composite material is proven to be reliable for rapidly microwave assisted regeneration. Both the regeneration temperature and O_2 composition in the supplied gas played an important role in the regeneration process.

Introduction

Diesel engines are superior to conventional gasoline engines with regard to fuel consumptions, which reduces CO_2 emissions and helps suppress global warming. These engines, however, produce more NO_x as well as particulate matter (PM) [1]. In response to the environmental and health concern from the emission of diesel particulate matter (DPM), governments over the world have continued to impose more stringent regulations restricting its emissions. Among techniques that have been designed to reduce the particulate emission, diesel particulate filters (DPF_s) have been considered as the best option. However, with accumulation of the DPM in the filter media, the pressure drop across the filter increase which in-turn exerts a back pressure on the engine exhaust, resulting in gradually poorer engine performance. Therefore, effective regeneration of the filter by continuously or periodically burning off the trapped DPM is of important.

Self regeneration of DPM is not possible due to high ignition temperature, typically 500 – 650 ^oC [2], and low engine exhaust temperature, generally lower than 400 ^oC. Therefore, an additional measure is needed to get rid of the trapped soot. Few studies utilizing microwave power for the regeneration of trapped filter has been reported in the literature [3-7]. Microwave heating significantly differs from conventional heating, as the energy is strongly concentrated in the material itself. Microwaves penetrate the material at a depth depending on the dielectric permittivity, resulting in a heating from the inside out. Microwave heating is very rapid and selective. With the choice of proper material as filter substrate, it can easily provide high temperature needed for DPM combustion and DPF regeneration [6-8]. In additional, microwave energy can be deposited directly to the DPM which is collected in the DPF. However, microwave assisted DPF regeneration has been experienced with uneven energy distribution which result in hotspots during DPM oxidation reaction [9].

The primary aim of the present work was to fabricate a filter material which can be heated up evenly by microwave for DPM regeneration. A porous glass-metal composite has been developed to serve as the DPF instead of using cordierite honeycomb ceramics. Experiments have been conducted in a 2.45 GHz (2 kW) single mode applicator to measure the efficiency of regeneration of the fabricated filter by varying the regeneration temperature and oxygen content.

Experimental Details

Glass /stainless steel (SS) porous composite bodies were produced by polyurethane sponge replica method using a slurries containing mixture of SiO_2·RO/ 10-30 vol% SS. The slurry was prepared by dispersing the powder mixture with distilled water without any further additives to give a suspension with approximately 40 wt% solids loading. According to Sifontes et al. [10], this weight allowed obtaining adequate viscosities of slurry and proper mechanical strength for ceramic foam.

Microwave heating of the obtained composite filter was conducted prior to regeneration test to evaluate their heating behavior. Subsequently, filter that has been preloaded with artificial soot (carbon black, (PRINTEX from Dagussa Corp.) was placed in the microwave applicator so as to have its axis coincident with the applicator axis. Apparatus for microwave regeneration is illustrated in Fig. 1. Detail of the single mode applicator is reported elsewhere [11]. Temperature was measured by an optical pyrometer which has a lower detection limit of 350 ^{o}C. Temperature-programmed regeneration (oxidation of the soot deposited filter) was performed under pure air condition, O_2/N_2 (21%/79%). In each test, filter temperature was raised from room temperature to 640-680 ^{o}C at a maximum heating rate (attained 600 ^{o}C around 13 s) and maintained at the target temperature for 1 to 3 min. The concentration of O_2, CO_2 and CO gases at the outlet was analyzed using a Hodakatest HT-2700 gas sampling device. In addition, effect of O_2 composition in the inlet gas stream on the regeneration process was also being evaluated.

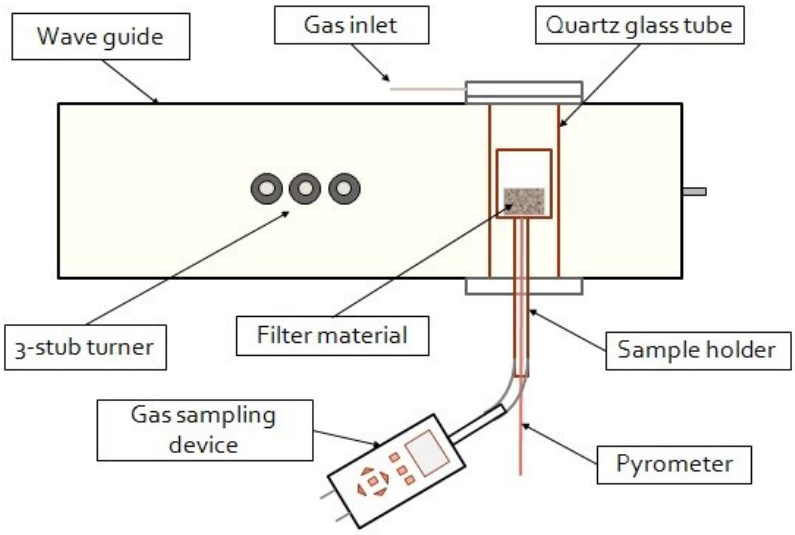

Fig. 1 Scheme of apparatus for microwave regeneration

Results and Discussion

Fig. 2 shows the microstructure of the skeleton surface with different stainless steel fraction. The SiO_2·RO matrix had a grey appearance whereas the stainless steel particles were in light grey. No obvious remnants of the PU sponge were detectable. Stainless steel particles were well dispersed and distributed within the glass matrix, increasing with the increased of stainless steel fraction in the mixtures. This microstructure effect was generated during the impregnation process. Since the stainless steel powder has a higher density compared to SiO_2·RO glass powder, segregation might occur in the slurries which could draw in non-homogeneity that will influence the uniformity of the stainless steel particle distribution within the glass matrix. Hence, uninterrupted stirring is needed during the impregnation step, to minimize the occurrence of segregation.

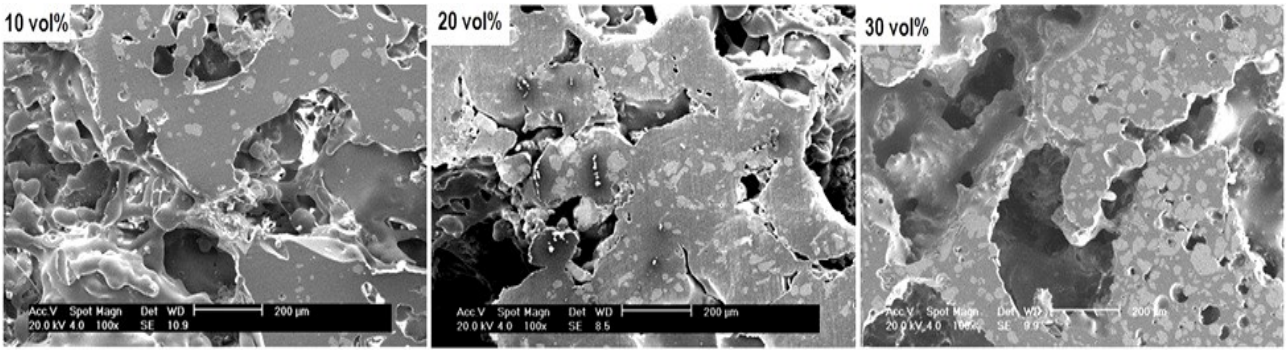

Fig. 2 SEM micrograph of sintered glass-stainless steel porous composite with different stainless steel fraction.

Microwave heating ability of the fabricated porous glass-stainless filter was studied using a 2.45 GHz, 2 kW, single mode applicator. The heating ability of these products is illustrated in Fig. 3. It revealed that, heating rate of the porous composites was fully associated with the amount of stainless steel particle in the sample. As the fraction of stainless steel in the mixtures increased, the heating rate also increased. Samples with higher metal fraction can be heated up rapidly as compared with those of lower metal fraction.

Effect of heating temperature and O_2 concentration in the gas stream on the regeneration of soot loaded filter are presented in Fig. 4. As can seen in Fig. 4, total CO_2 and CO concentration increased as the regeneration temperature keep on increasing (up to 660 ^oC). Above this temperature it shows a steady constant value due to saturation of the carbon oxidation rate. At low regeneration temperature, conversion rate of the soot was mainly determined by the reaction rate, whilst at a higher regeneration temperature, mass transfer rate determines the conversion rate.

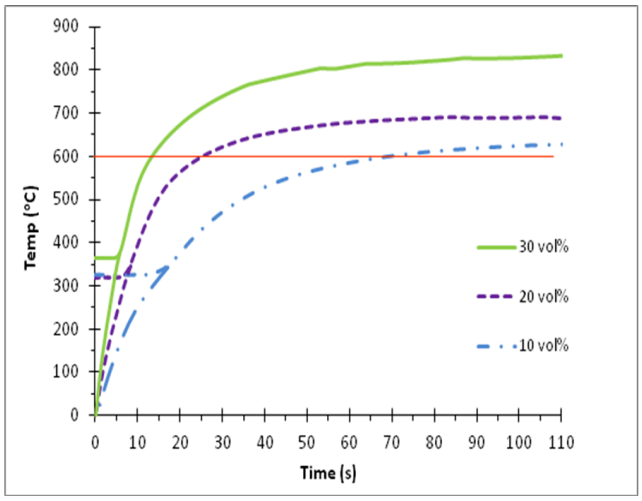

Fig. 3 Heating curve of porous glass-stainless steel with differents stainless steel fraction

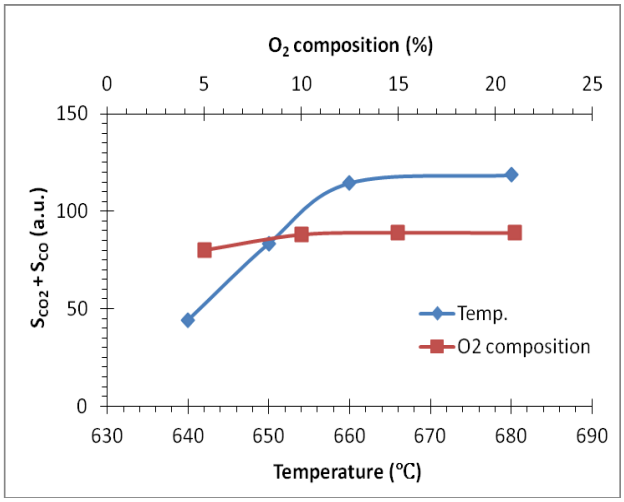

Fig. 4 CO_2 and CO concentration as a function of regeneration temperature and O_2 composition

Completely soot free filter with a regeneration efficiency of as high as 99 % can be achieved. Thus, for the remaining experiments, filter regeneration temperature was set at 680 ^oC. Indicated in the figure also, total CO_2 and CO concentration was gradually increased with the increasing of O_2 composition. As a consequence, it is definite that compositions of O_2 present in the gas stream have a significant effect on the regeneration process, as expected. With higher oxygen composition in the gas stream, more oxygen is supply to the system for combustion, which can promotes the oxidation rate and conversion of carbon to CO_2.

Conclusions

(1) Porous glass-stainless steel composite with interconnected pores and high porosity (65-70%) were obtained by the sponge replica method. The porous SiO_2·RO/SUS composite consist of well dispersed and distributed stainless steel particles within the SiO_2·RO glass matrix. Samples with higher stainless steel volume fraction shows a better and faster heating by microwave.

(2) Both the regeneration temperature and oxygen composition in the supplied gas stream shows a significant effect on the oxidation and conversion rate of carbon. Higher regeneration temperature and oxygen composition is preferable for the full regeneration of soot loaded filter, which is at least or higher than 660 ^{o}C with an O_2 composition of 15 % or higher respectively.

Keywords: Metal foam, sandwich structure, lost carbonate sintering, fracture

Abstract: The fracture properties of a series of metal foam sandwich structures based on glass fiber-reinforced polyamide 6,6 composite (GF/PA6,6) skins have been investigated. The open cell core materials were manufactured using the Lost Carbonate Sintering (LCS) process, a recently-developed technique for manufacturing metal foams. Initially, the effect of varying the compaction pressure used in producing the metal foams as well as the density of the samples were investigated through a series of compression tests. Here, it was shown that the compressive strength and the elastic modulus of the foams varied with density and compaction pressure, in spite of the fact that the average size of the cells in these foams were insensitive to either of these two parameters.
The resistance of sandwich structures to localized loading was investigated through a series of indentation tests. Here, it was shown that the indentation response of sandwich structures could be characterized using a simple indentation law, the parameters of which did not exhibit any clear dependency on the density of the foam. Finally, three point bend tests on the sandwich structures have shown that their loading-bearing properties were sensitive to foam density.

Introduction

Traditional fiber reinforced sandwich structures are based on polymer core materials, however, polymer foams typically offer a relatively low strength and only a moderate energy-absorbing capacity. Recently, a range of lightweight metallic core materials offering higher strength, stiffness and energy absorption characteristics have been developed for applications in the aerospace, land and marine sectors [1-5]. Currently, there are a number of processing technologies used in the manufacture of metal foams. Frequently, a liquid-state foaming route is employed for manufacturing low-melting-point metal systems such as aluminum foam [2]. In contrast, high-melting-point metal cores are usually manufactured by a solid state method such as a powder metallurgy process. However, many commercial aluminum foams offer cell sizes between 2 and 10 mm. Recently, the introduction of the Lost Carbonate Sintering (LCS) process has enabled researchers to manufacture open-cell metal foam structures with well-controlled cell dimensions at very low cost [6-13]. The work presented in this paper investigates the properties of a metal foam-based sandwich structure based on glass fiber-reinforced composite skins. Iron powder was employed to manufacture the metal foams via the LCS process. Iron foam offers several advantages over aluminum foam, including a higher strength and stiffness, lower raw material costs and a higher melting temperature [14]. Initially, the mechanical properties of the foam materials are investigated through a series of compression tests on cylindrical samples. Following this, the indentation and flexural properties of sandwich structures based on glass fiber reinforced polyamide 6,6 composite skins are investigated.

Experimental procedure

The iron foam cores investigated in this study were manufactured using the Lost Carbonate Sintering (LCS) process, a procedure that is described in detail elsewhere [7]. The raw materials used here were based on iron powder (supplied by Pometon Metal Powders), potassium carbonate (K_2CO_3) spheres (supplied by E&E Ltd in Widnes, UK) and glass fiber reinforced polyamide 6,6 (TEPEX) composite skins (supplied by Bond Laminates, Germany). The iron powder used in this study (FERSINT RI 180/3.0) was supplied with a particle size between 25 and 200 μm and the K_2CO_3 spheres used in the LCS process were in the size range of 710 to 1000 μm. The thickness of the glass fiber reinforced polyamide 6,6 composite used in the manufacture of the skins was 0.5 mm. The nominal volume fraction of iron in the Fe-K_2CO_3 mixtures was 0.25, 0.3 and 0.35, yielding metal foam samples with nominal relative densities of 0.2, 0.25 and 0.29, respectively. The Fe-K_2CO_3 mixtures were sealed in cylindrical mild steel tubes by placing iron powder in the two ends. The samples were compacted by a press prior to sintering. Three compaction pressures were used during the manufacture of the foam samples, these being 100, 150 and 200 MPa. Following compaction the samples were sintered in a temperature-controlled electrical furnace. The temperature in the furnace was increased at a rate of 10℃ per minute from room temperature to 850℃ and samples were sintered at this temperature for 4 hours. After the sintering process was complete, the K_2CO_3 particles were dissolved in running water for 90 minutes. The resulting metal foams were subsequently dried in an oven for two hours at a temperature of approximately 100℃. This process yielded high quality foams with an open-cell structure.

A series of mechanical tests were carried on foams manufactured using compaction pressures of 100, 150 and 200 MPa. The iron foam specimens used in these compression tests were based on 20 mm diameter, 10 mm high cylinders. The compression tests were carried out on an Instron 4505 universal test machine at a crosshead displacement rate of 1 mm/min. Following the compression tests on the plain iron foam samples, a series of sandwich structures were manufactured to evaluate the potential offered by such core materials. Here, an Araldite LY5082 epoxy resin combined with an Araldite AY 103 hardener was used to bond the core and glass fiber/polyamide 6,6 skin materials. After the resin was applied, the sandwich beams were placed under a light pressure and left overnight at room temperature to ensure complete curing of the adhesive. Initially, indentation tests were conducted on sandwich beams positioned on a solid base. Samples with dimensions of 120 x 25 x 25 mm (manufactured using a compaction pressure of 100 MPa) were tested on an Instron 4505 mechanical test machine at a crosshead displacement rate of 1 mm/min. The diameter of the indentor was 10 mm and the maximum indentation was approximately one millimeter. Three point bend tests were conducted on samples with dimensions of 120 x 25 x 25mm (a compaction pressure of 100 MPa was used due to limitations in the capacity of the press) on an Instron 4505 universal test machine. The beams were supported on two 10 mm diameter cylinders positioned 100 mm apart. A 10 mm diameter steel indentor was used to load the samples at a crosshead displacement rate of 1 mm/minute.

Results and Discussion

Compressive properties of the core materials

Fig. 1 shows the microstructures of the three densities of iron foam manufactured using compaction pressure of 200 MPa. Fig. 1a, the sample with a relative density of 0.2 indicates that many of the cell walls have not fully formed during the sintering process and a number of cell walls have fractured, possibly during the subsequent grinding process. The microstructures of the foams with relative densities of 0.25 and 0.29, Figs. 1b and 1c, are better defined, with the individual cells being more clearly visible. Closer examination highlights the fact that some cells here effectively merged and the cell wall is missing. This occurs when two potassium carbonate particles are in very close proximity and the metal powder is forced out. The average diameters of cells in the three foams were measured and Fig. 1 shows the variation of the average cell diameter with relative density. Clearly, the

average cell sizes in the three types of foam are similar suggesting that the size of the cells does not vary over the range of densities considered. It is evident from the micrographs and the data in Fig. 1 that the average cell size reflects the size of the potassium carbonate particles used in the manufacture of the foams. Fig. 2 shows the variation of cell size with compaction pressure where it is again evident that the size does not vary over the range of manufacturing conditions studied here. The degree of voiding in the cell walls decreased as the compaction pressure was increased, indicating that the higher manufacturing pressures produced a greater level of contact during the sintering stage. Clearly, the size of the cells in these systems is significantly smaller than those observed in commercially available metal forms where values in the latter can be as large as 10 mm [15].

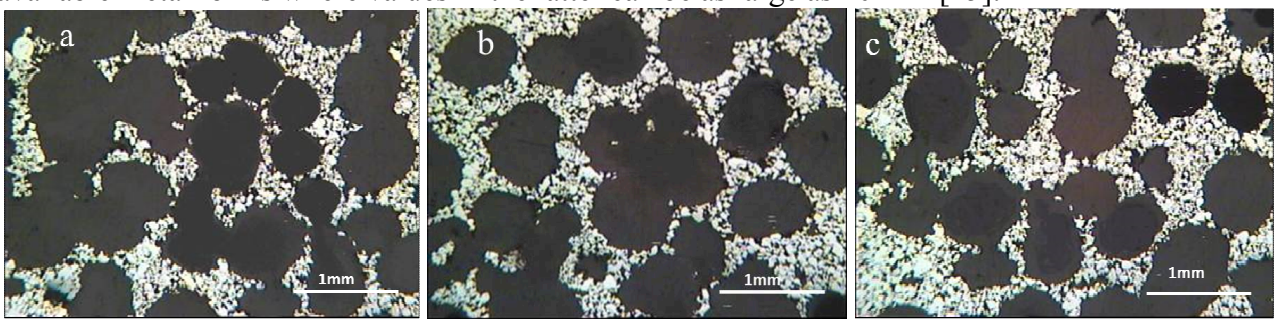

Fig. 1 Microstructure of the foam cell, (a) relative density of the foam was 0.20, (b) relative density of the foam was 0.25, (c) relative density of the foam was 0.29.

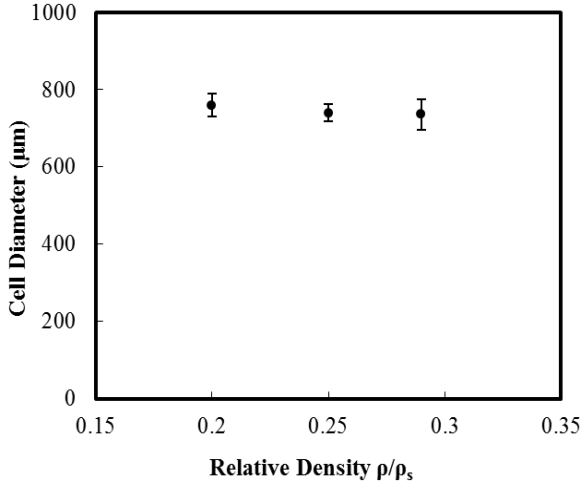

Fig. 2 The variation of cell diameter with relative density for foams manufactured using a compaction pressure of 200 MPa.

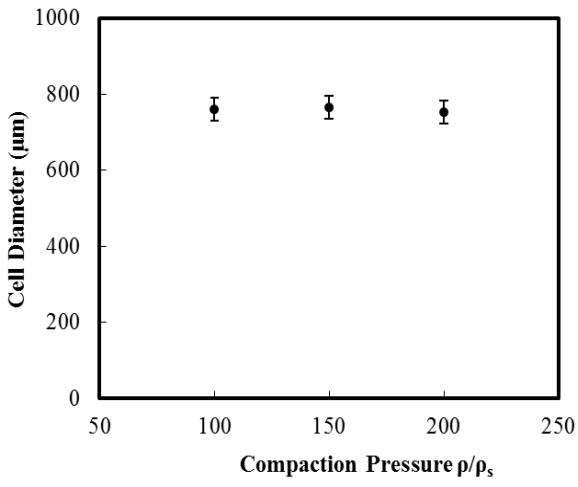

Fig. 3 The variation of cell diameter with compaction pressure for foams with a relative density of 0.25.

Fig. 4 shows typical stress-strain traces following compression tests on samples manufactured using compaction pressures of 100, 150 and 200 MPa. In each case, the relative density of foams was nominally 0.25. The curves in Fig. 4 exhibit a region of linear elasticity at low stresses, followed by a long plateau stress before the stress rises steeply in the regime of densification. Included in the stress-strain trace for the 200 MPa sample is the procedure for determining the plastic collapse stress, σ_{pl}. The figure shows that increasing the compaction pressure serves to increase both the plastic collapse stress and the stress at the onset of densification (the final rise in the stress-strain plot). Fig. 5 shows sections removed from samples that had been subjected to strains ranging from 0.2 to 0.5. An examination of the micrographs indicates that the samples fail due to the cell wall buckling and collapse under the increasing strain. At a strain of 0.2, Fig. 5a, a number of cell walls close to the top of the sample fail causing strain localization. With increasing strain, the regions in which cell wall buckling occurs increase in size, spreading out across the sample. At a strain of 0.5, Fig. 5d, virtually all of the cell walls have collapsed and densification occurs. Fig. 6 shows the variation of the plastic collapse stress of the foams, σ_{pl}, with compaction pressure. Clearly, the plastic collapse stress

increases rapidly with the level of pressure applied during compaction, indicating that this processing parameter has a significant effect on the mechanical properties of the foam. As previously stated, increasing the compaction pressure forces the metal particles into contact during the sintering process, leading to fewer voids in the cell walls following manufacture.

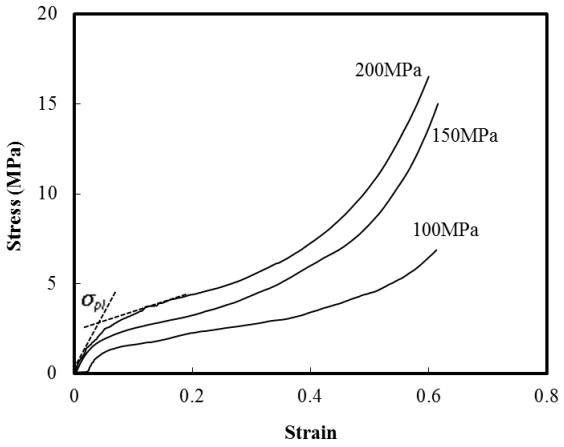

Fig. 4 Typical stress-strain curves following compression tests on samples manufactured using compaction pressures of 100, 150 and 200 MPa. The relative density of the foam was 0.25.

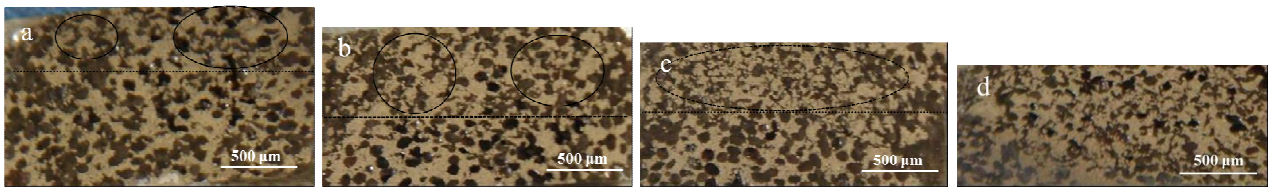

Fig. 5 Deformation banding during a typical compression test: (a) ε=0.2, (b) ε=0.3, (c) ε= 0.4, (d) ε=0.5.

Fig. 7 shows typical compression stress-strain curves following tests on the three different densities (0.20, 0.25 and 0.29) of metal foam manufactured using a compaction pressure of 200 MPa. It is clear from Fig. 7 that the stress-strain response of the foam samples depends on the density of iron foam; this phenomenon was also observed by Park et al [14]. Lowering the density of the foam gives a more pronounced plateau since the structure affords more opportunity for cell walls to deform and collapse during the loading process. The variation of the plastic collapse stress with relative density is shown in Fig. 8. Clearly, the compressive properties of the foam increases rapidly with foam density. The compressive properties of these foams compare favourably with previously published data for an aluminum foam where values of compression strength of approximately 1.5 MPa were recorded [15].

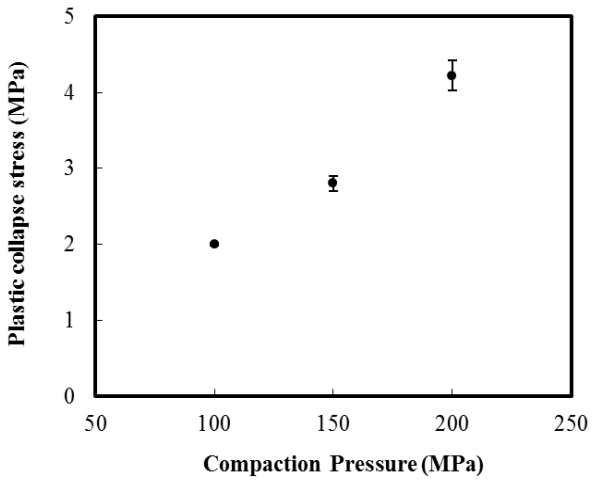

Fig. 6 The variation of compressive stress with compaction pressure. The relative density of the foam was 0.25.

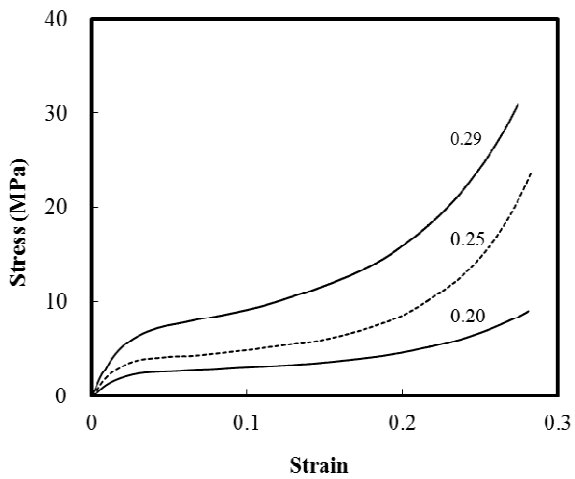

Fig. 7 Typical stress-strain curves following compression tests on samples manufactured using a compaction pressure of 200 MPa.

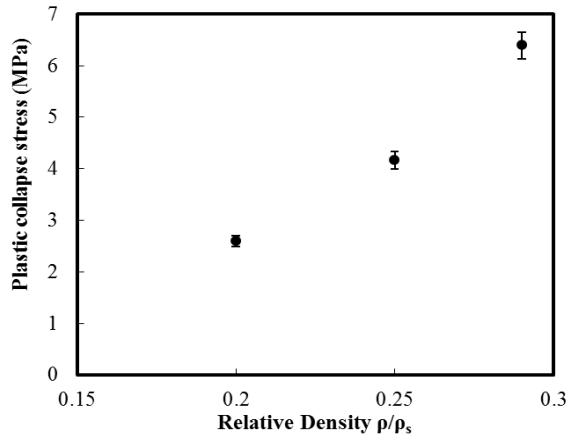

Fig. 8 The variation of compressive stress with relative density for foams manufactured using a compaction pressure of 200 MPa.

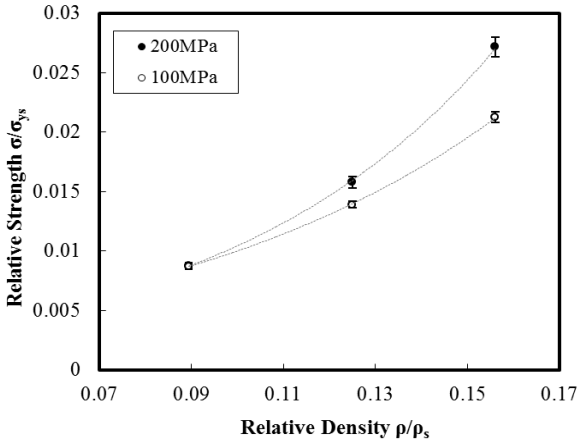

Fig. 9 The variation of relative strength with relative density for foams manufactured using compaction pressures of 100 MPa and 200 MPa.

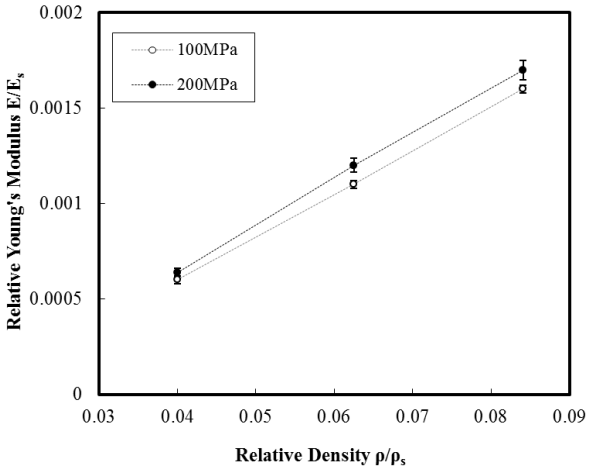

Fig. 10 The variation of the relative Young's modulus with relative density for foams manufactured using compaction pressures of 100 MPa and 200 MPa.

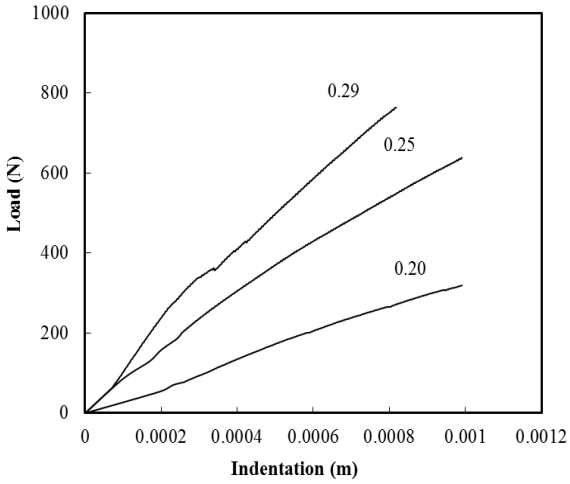

Fig. 11 Typical load-indentation curves for the sandwich structures manufactured using a compaction pressure of 100 MPa.

Table 1 summarises the average plastic collapse stresses of the foams considered here. Clearly, the plastic collapse stress of the foam is sensitive to both density and compaction pressure. The strength data for the iron foam are plotted as a function of relative density in Fig. 9. Previous work [3] investigating the compressive properties of open-cell foam structures has shown that the relative plastic-collapse stress, σ_{ys}, of such a structure can be written in the form:

$$\frac{\sigma_{pl}}{\sigma_{ys}} = \mathrm{M}\left(\frac{\rho}{\rho_s}\right)^{3/2} \tag{1}$$

where ρ/ρ_s is the relative density, σ_{ys} is the yield strength of the solid material and M is a constant with a value equal to approximately 0.3 [3]. In this study, the data from the compression tests were forced to fit this type of relationship, yielding a value for M. The data in Fig. 10 were used to determine the appropriate values of M in Equation 1. Table 2 summarizes the average values of M where it can be seen that the experimentally-determined values are well below the values of 0.3 predicted by a cubic model for open-cell foams [3]. Since the model assumes a cubic cell geometry and the iron foams are clearly more irregular than this, some significant deviation between the measured and predicted behavior is expected.

TABLE 1 SUMMARY OF THE PLASTIC COLLAPSE STRESSES OF THE METAL FOAMS.

Relative density	Compaction Pressure (MPa)		
	200 MPa	150MPa	100 MPa
0.20	2.18		
0.25	4.30	2.80	2.00
0.29	7.24		

TABLE 2 SUMMARY OF THE CONTACT PROPERTIES OF THE METAL FOAMS [3].

	Theoretical value	Compaction Pressure (MPa)	
		100	200
M	0.3	0.144	0.174
C	1	0.018	0.018

The relative Young's modulus properties of the foams are summarized in Fig. 10. Previous work has shown that the relative Young's modulus of a foam, E/E_s, (where E_s is the Young's modulus of the solid material) can be written in terms of its relative density, ρ/ρ_s, as follows [3]:

$$\frac{E}{E_s} = C\left(\frac{\rho}{\rho_s}\right)^2 \tag{2}$$

where C is a constant (approximately equal to unity for an open cell foam [3]). As before, this relationship was applied to the experimental data, yielding a value for the constant C. Table 2 reports the values of C for the systems evaluated here. It is clear that the measured values for this constant are significantly lower than those predicted by the cubic cell geometry.

Indentation characteristics of the sandwich structures

Fig. 11 shows typical load-indentations plots following tests on the three sandwiches manufactured using a compaction pressure of 100 MPa. Clearly, the slope of the load-indentation trace increases with foam density. It can be seen from the figure that the initial portions of the curves were slightly non-linear, and effect that may be due to the compliance of the test machine and a slight lack of fit in the test fixture. The reason for the change of slope in the sandwich structures was explained by Davies et al [16], who attributed it to the initiation of local damage such as core crushing under the point of indentation. The load, P, versus indentation, α, plots were forced to fit a generalized contact law of the form:

$$P = C\alpha^n \tag{3}$$

where n and C are indentation parameters that can be determined from the load-indentation plots. The type of relationship has been successfully used in previous studies investigating the indentation response of sandwich structures [17] and was considered appropriate here. Plots of *log P* versus log α were drawn, to yield the indentation parameter 'n' (from the slope of the graph) and the constant '*C*' (from the intercept with the y-axis).The values of the parameters *n* and *C* in this indentation law are summarized in Table 3, which dictate the shape and slope of the indentation trace [17]. The load-indentation curve should be a straight line when n is equal to unity, the curve will tend upwards when n is greater than one and downwards when n less than one. The value of *C* determines the effective gradient of the curve.

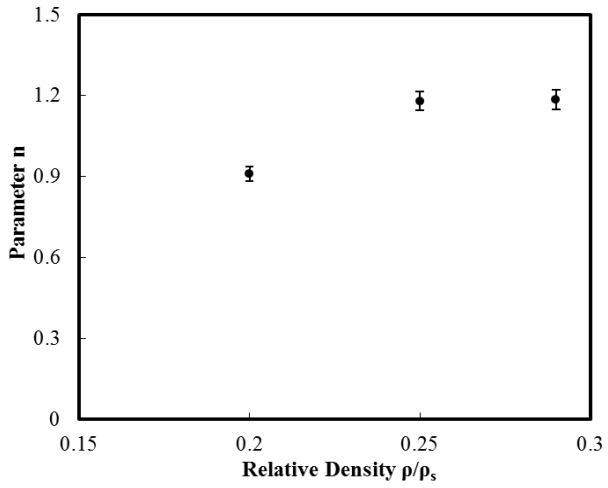

Fig. 12 The variation of the contact parameter, n, with relative density for foams manufactured using a compaction pressure of 100 MPa.

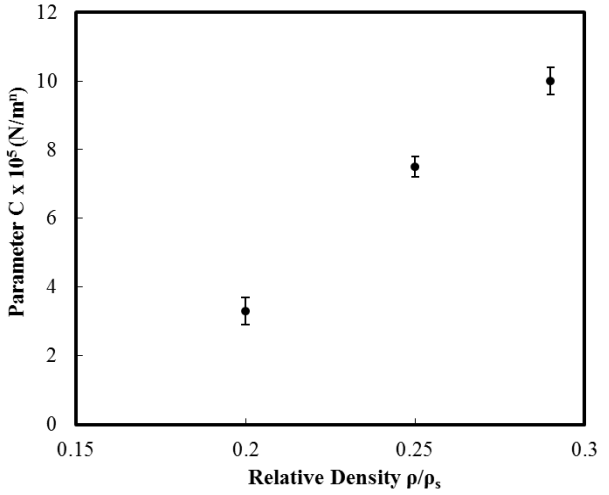

Fig. 13 The variation of the contact parameter, C, with relative density for foams manufactured using a compaction pressure of 100MPa.

TABLE 3 SUMMARY OF THE CONTACT PROPERTIES OF THE SANDWICH STRUCTURES FOLLOWING INDENTATION TESTS.

Relative Density	C (N/m^n)	n
0.2	3.3×10^5	0.91
0.25	7.5×10^5	1.18
0.29	1.0×10^6	1.185

The variation of the parameter 'n' with relative density is shown in Fig. 12; the average values of 'n' for the 100 MPa samples varied between 0.91 and 1.185. It can be seen that for the samples with a relative density of 0.2, the average values of 'n' are lower than unity, approximately 0.91. In contrast, samples with relative densities of 0.25 and 0.29, the average values are clearly greater than unity. Similar results were observed when the parameter 'C' is plotted against relative density as shown in Fig. 13. The average values of 'C' show an increasing trend with increasing relative density. This is expected since increasing the density of the foam increases the stiffness of the sandwich structure, thereby increasing the effective slope of the load vs. indentation curve.

Flexural properties of the sandwich structures

Fig. 14 shows typical load-displacement curves following three-point bending tests on the sandwich structures. Fig. 15 shows a photograph of a fractured sandwich structure following a three-point bend test, the relative density of the foam in this sample was 0.25. From the figure, it can be seen that the core has fractured in shear at one end of the sample leading to debonding of the composite skin along the uppermost interface. Similar failure modes were observed in the samples based on foams with relative densities of 0.2 and 0.29. Clearly, the load-bearing capacity of the sandwich structures is limited by the fracture properties of the core. Similar modes of failure have been observed following three-point bend tests on aluminum foam core sandwich structures based on glass fiber PA 6,6 skins [15].The maximum stress in the lower composite skin at maximum load was determined using sandwich beam theory. Here, the maximum tensile stress in the lower face is given as:

$$\left(\sigma_f\right)_{\max} = \pm \frac{ME_f}{D}\frac{h}{2} \tag{4}$$

where M is the maximum bending moment, E_f is the modulus of the composite skins and D can be approximated as [1]:

$$D = E_f \frac{btd^2}{2} \tag{5}$$

where the dimensions b, t and d are defined in Fig. 16.

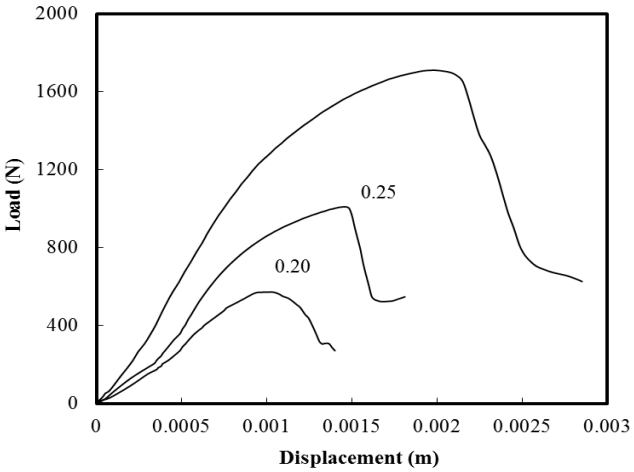

Fig. 14 Typical load-displacement curves following three point bend tests on sandwich structures manufactured using a compaction pressure of 100 MPa.

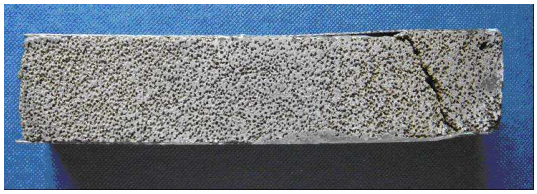

Fig. 15 The photograph of deformed sandwich structure after three point bend testing, relative density of foam was 0.25.

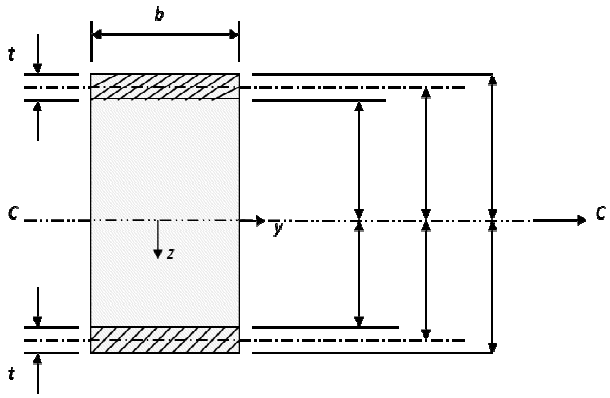

Fig. 16 Schematic of the cross-section of a sandwich beam showing the characteristic dimensions.

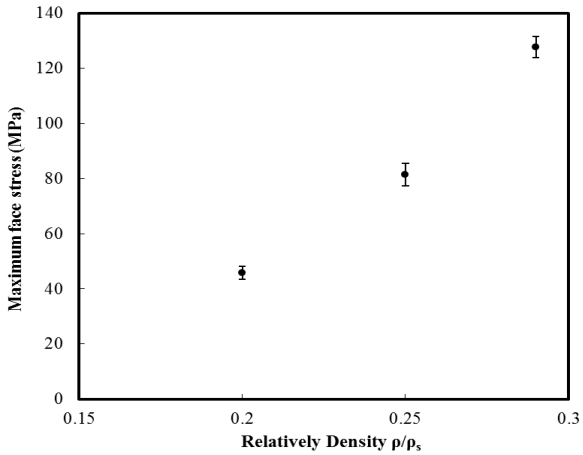

Fig. 17 The variation of the face stress with relative density for sandwich structures manufactured using a compaction pressure of 100 MPa.

The average values of the maximum stress in the face material were calculated using Eqn. 4 and these values are shown in Fig. 17. From the figure, it is clear that the stress in the lower skin at failure increases as the relative density increases. The maximum stress in the skins in the highest density laminate was approximately 130 MPa, this being approximately thirty percent of the tensile strength of the composite skins. Clearly, the strength of the sandwich structures is limited by the shear strength of the core, increasing as the shear strength of the core increases. These findings do suggest, however, that the LCS technique offers potential for manufacturing low cost metal foam cores for use in the manufacture of sandwich structures. The LCS technique is currently being used to manufacture metal cores based on other metal alloys such as steel and nickel-titanium shape memory alloys.

Summary

A range of iron foam core sandwich structures have been manufactured by the LCS process. Initial tests to characterize the mechanical properties of core materials have shown that the compressive strength and the elastic modulus of the systems were sensitive to the relative density of the foam and the compaction pressure used during manufacture. The compressive strength of the foams was also sensitive to the geometry of the foam.

Indentation tests on the sandwich structures have shown that the load-indentation response of these systems can be characterized using a generalized indentation law. Subsequent three point bend tests have shown that the load-bearing properties of these systems are also sensitive to the relative density of the core.

Keywords: Matrix Microstructure; Cast Iron; High-speed Dry Sliding; Friction and Wear

Abstract: The friction and wear properties of cast iron with different graphite morphologies and matrix microstructure were investigated at high speed dry sliding against GCr15 steel on the MMS-1G high-speed tribometer apparatus. The various wear micro-mechanisms and tribo-metallographic phases were studied by using scanning electron microscopy. The results show that as friction material, vermicular iron exhibits excellent comprehensive tribological properties. The friction coefficient of cast iron sliding against GCr15 decreases while the wear rate increases with the increase of sliding speed, friction coefficient and wear rate decline with the increase of pearlite content. Under the experimental condition, the main wear mechanisms of flake iron are abrasive wear, of vermicular iron are abrasive wear and oxidative wear and of nodular iron are oxidative wear, abrasive wear and fatigue spalling.

Introduction

Above half of world energy was consumed in different forms by the friction of friction pair components of machinery taking place on the rubbing surfaces[1]. Hence, tribologists at home and abroad implemented in succession research on tribological properties of material at high speed dry sliding[2,3]. As one of the commonly used materials, cast iron has a series of virtues such as abundance in resources, low price, simple to produce, etc. Meanwhile graphite morphology and matrix microstructure may produce significant influence on mechanical properties and tribological properties[4-5]. Hence, in this study an attempt has been made to investigate tribological properties of flake iron, vermicular iron, nodular iron with different matrix microstructures sliding against GCr15 bearing steel on MMS-1G high-speed tribometer apparatus, and the objective of present work is to establish the foundation for cast iron in dry sliding frition applications.

Experimental details

Cast Iron Pin Sample Preparation. The compositional details of pin samples with identical chemical composition are presented in Table 1. Through inoculation, spheroidising and vermicularizing flake iron blank, vermicular iron and nodular iron blank tested in this study were obtained. Moreover, green sand casting was employed to produce all the pin samples. Each type of pin sample was subjected to different heat treatments to obtain three matrix, the specific process is as follows:normalizing and 550℃ high temperature tempering were processed to obtain pearlite matrix;The pin sample with ferite matrix was achieved by means of high temperature graphitization and annealing; 880 ℃ normalizing and 550℃ high temperature tempering caused the formation of mixed matrix microstructure, and the holding time is（2.4min/mm）×52.5 mm. The pin samples were obtained in form of Φ14mm ×40mm using wire cutting.

Table 1 Chemical composition of cast iron（mass fraction/%）

C	*Si*	*Mn*	*P<*	*S<*
3.6	*2.5*	*0.6*	*0.07*	*0.03*

Counter-disc Preparation. GCr15 bearing steel used as rotating counter-surface was in the form of 160-mm diameter discs. All the rubbing discs have undergone quenching and low tempering to have surface hardness of 57~60 HRc. The nominal chemical composition of discs is shown in Table 2.

Table 2 Chemical composition of GCr15 bearing steel（mass fraction /%）

0.95～1.05	*0.25～0.40*	*0.15～0.35*	*0.020*	*0.027*	*1.30～1.65*

Sliding Wear Tests. Sliding wear tests were conducted using MMS-1G high-speed tribometer apparatus allowing maximum sliding speed of 100m/s and maximum load of 3MPa. Sliding speed adopted in the study was 10,30,50,70 and 90m/s, and the variable load was changed from 0.33 to1.67 MPa. Preliminary tests were first conducted on all pins samples to ensure good contact between pin and counter-surface before each test. An average of three observations has been considered in this study.

Dry Tribological Properties. Friction coefficient was determined by recording the friction force with the help of a friction transducer, and computered by the following expression：

$$\mu = \frac{F}{N} \tag{1}$$

μ：friction coefficient; F: frictional force calculated by friction torque/fricton arm; N: normal press. Wear rate is calculated following the expression（2）.

$$W = \frac{\Delta W}{2\pi R t n \mu N} \tag{2}$$

W：Physical significance stands for wear loss of unit friction work.Where R is average friction radius(m), namely, the distance of pin from the center of the disc; t: sliding time(s); n: rotational speed of disc(r/min); N is the normal stress applied on pin(N); μ:friction coefficient;Wear loss ΔW was measured by the weight loss of pin samples measured with the help of BS210S weighing balance of accuracy 0.1mg.The samples were cleaned well with alcohol and then dried prior to and after wear testing.

Microstructure Analysis. Worn surfaces of cast iron were observed by JSM-5610LV scanning electron microscopy to analyze wear mechanism.

Experimental Results

Effect of Graphite Morphology on Tribological Behaviour

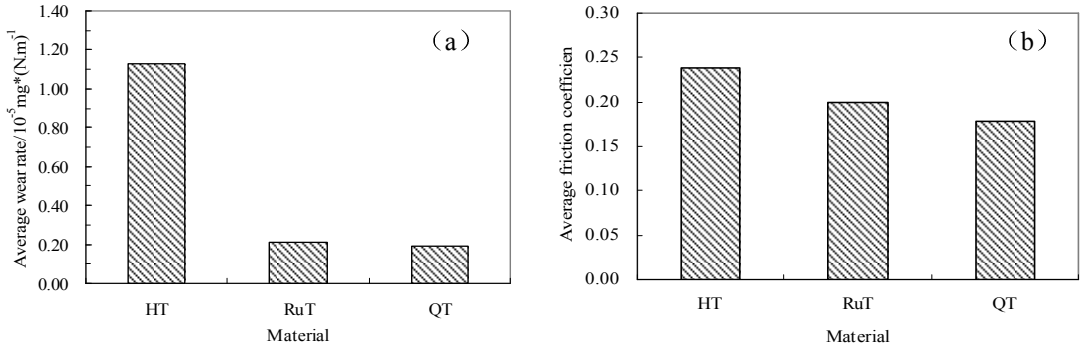

Fig.1 Effect of different graphite morphology on tribological behaviour of cast iron

Average friction coefficient and average wear rate of cast iron with different graphite morphologies are showed in Fig.1 under different conditions. It shows that RnT attained higher friction coefficient than that of QT and significantly less wear rate than that of HT irrespective of test conditions and matrix microstructure.

Wear resistance of the cast iron depends largely on graphite morphology when all the samples attained one type of matrix microstructure. Firstly,graphite morphology may affect strength and toughness of cast iron,and the change of flake graphite converted into to vermicular graphite or

nodular graphite could lead to an increase in strength and toughness of cast iron resulting in superior wear resistance.On the other hand, graphite morphology may also affect thermal conductivity of cast iron.Flake graphite and vermicular graphites may form a bond with each other in one eutectic cell causing an increase in thermal conductivity as compared to QT.Under similar conditions, it is expected that QT achieved the highest friction surface temperature causing severity of surface and subsurface regions damage and the ability of plastic deformation.As a whole,RuT exhibited superior comprehensive tribological properties due to the better thermal conductivity as compared to that of QT and graphite vermicular contributed to more superior strength and toughness in comparison with HT for friction material.

Effect of Matrix Microstructure on Triboligical Behaviour

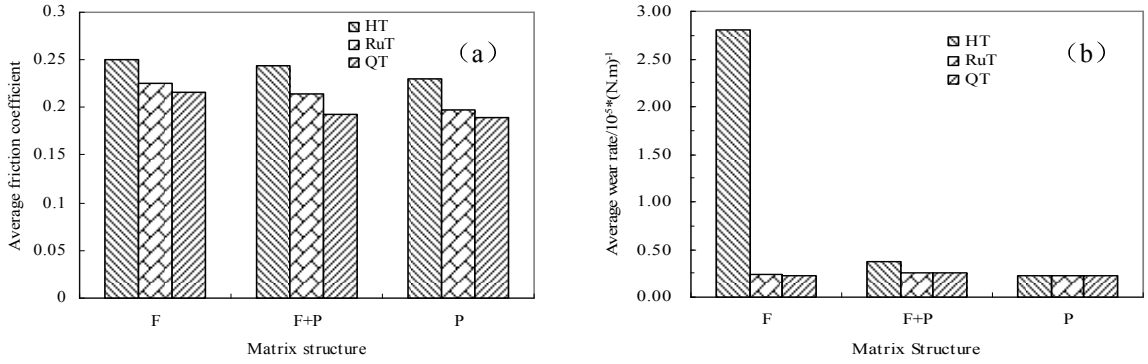

Fig.2 Effect of different matrix microstructures on triboligical behaviour of cast iron

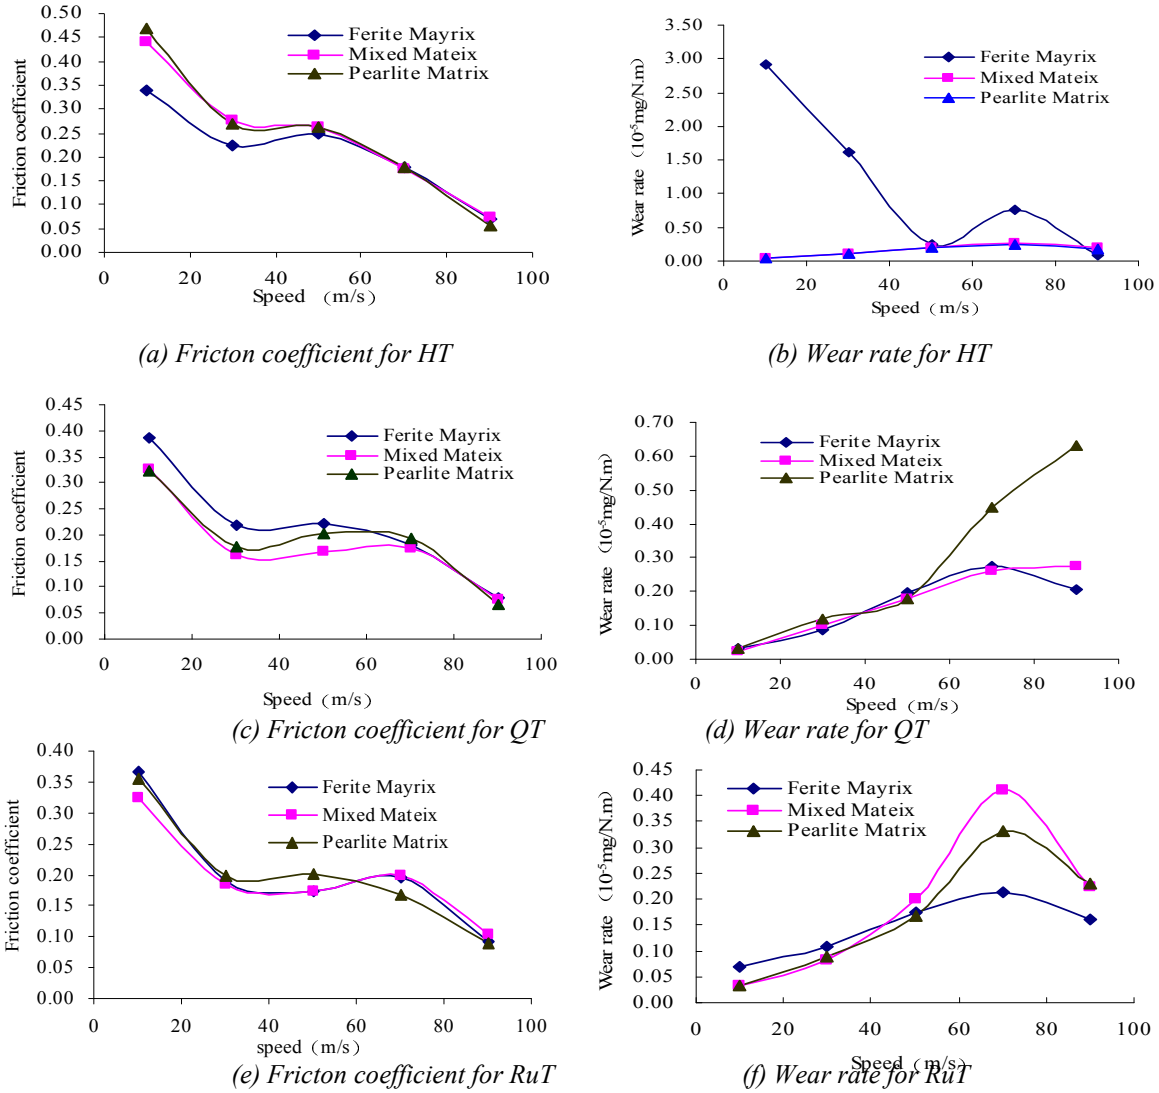
Fig.2(a) represents the average friction coefficient of HT, RuT, QT with different matrix microstructures tested under different conditions.The testing results show that friction coefficient of HT deceased slightly with increasing pearlite content, similar trend occurred for RuT and QT,thereby higher content of pearlite is more beneficial for antifriction material.Higher content of ferite could lead better performance for friction material.

Fig.2(b) represents the average wear rate of HT, RuT, QT with different matrix microstructures tested under different conditions.It can be seen that verage wear rate of HT, Ru T, QT deceased with increasing content of pearlite,moreover HT with ferrite matrix attained significantly higher wear rate than that of all other samples tested,thereby higher content of pearlite generally leads to an increase in wear resistance of cast iron.



Effect of Sliding Speed on Triboligical Behaviour

The variation of friction coefficient of cast iron with sliding speed are shown in Fig.3(a), (c), (e).The results indicate that friction coefficien deceased with increasing sliding speed on controlled condition.As shown in Fig.3(a), (c), (e), there was a significant decease in friction coefficient of the samples tested with increase in sliding speed from 10m/s to 30m/s, accordingly suggesting that friction coefficient was quitely sensitive to the variation of sliding speed,with further increase in sliding speed to 30 and 70m/s, average friction coefficient recorded stabilised with the varition of sliding speed; At higher sliding speed(70~90m/s), significant decease in friction coefficient was observed with increasing sliding speed.

Fig.3(b), (d), (f) show the wear rate as a function of sliding speed of testing samples at 0.33MPa load. It can be seen that wear rate of cast iron increased in general with increasing sliding speed, in the case of cast iron with ferite matrix opposite, this is possibly due to severe abrasive wear at low sliding speed.

Wear Mechanism

The representative scanning electron micrographs for wear surface of cast iron with varying graphite morphologies at 90m/s speed and 0.33MPa load are shown in Fig.4.It can be observed that worn faces of flake iron showed large amount of microcracks and melt spots,deep and plough-hooked scratch indicating higher spalling probability of wear debris, thereby wear rate of flake iron remained higher than that of the other samples tested, and under act of alternative contact

(a) Fricton coefficient for HT *(b) Wear rate for HT*

(e) Fricton coefficient for RuT *(f) Wear rate for RuT*

Fig.3 Effect of sliding speed on triboligical behaviour of cast iron (0.33MPa）

stress,wear mechanism was dominanted by abrasive wear.The presence of oxide adhesion and limited quantity of grooves on the worn surface of RuT suggested abrasive wear and oxidative wear to be the dominant mechanism of material removal.Worn surface of QT showed a limited quantity of grooves, meanwhile the peeling phenomenon induced by stress concentration was also observed around graphite phase,thereby the main wear mechanism was combination of oxidative wear, abrasive wear and fatigue spalling.As a whole, it could be summaried that abrasive wear would lead to higher friction coefficient and wear rate, and oxidative wear could in turn decline friction coefficient due to the rubbing surface covered by oxidation film.

Fig.5 shows the worn surfaces of QT with different matrix microstructures.It can be observed that worn surface of pin sample with ferite matrix showed rough topography containing severe scratch in

(a)HT×500 (b)RuT×500 (c)QT×500

Fig.4 SEM morphology of the worn surfaces on pin sample of different graphite morphologies (at the sliding speed 90m/s and the load 0.33MPa）

form of groove and wear mechanism was dominanted by abrasive wear.Worn surface of pearlite matrix with large amount of particles was relative smoother in contrast with that of pearlite+ferrite matrix containing small amount of grooves.The presence of large amount of particles could be contributed to the increse of friction coefficient and wear rate, which was also in agreement with the trend of friction coefficient and wear rate with the varition of content of pearlite as shown in Fig.2(a),(b).EDS analysis showed that oxidation wear was observed on the worn surface of all the samples tested; Wear mechanism was dominanted by abrasive wear when the content of was higher, increased content of pearlite could lead to the change of wear mechanism varied from abrasive wear to combined action of abrasive wear, oxidative wear due to the severity of oxidation.

Fig.5 SEM morphology of the worn surfaces on pin sample with different matrix microstructures (QT: at the sliding speed 90m/s and the load 0.33MPa）

Conclusions

(1) In the present work, HT achieved the highest friction coefficient, next was RuT, whereas the lowest wear rate was obtained for QT, and then RuT, HT in order. In the view of above, RuT exhibited superior comprehensive tribological properties used as friction material.

(2) Average friction coefficient of all samples tested decreased slightly sliding against GCr15 steel with the increase in content of pearlite, and as for wear rate also.

(3) The friction coefficient of the tested samples deceased with increasing sliding speed sliding against GCr15 bearing steel. There was a significant decrease in the friction coefficient of the samples tested with sliding speed increased from 10m/s to 30m/s accordingly, suggesting that the friction coefficient is quite sensitive to the variation of sliding speed. With further increase in the sliding speed from 30m/s to 70m/s, friction coefficient recorded stabilised with the variation of sliding speed. At higher sliding speed (70~90m/s), significant decrease in friction coefficient was observed with increasing sliding speed. Wear rate of cast iron increased in general with increasing sliding speed.

(4) Under the test condition, the principal wear mechanism of flake iron was abrasive wear, and the principal wear mechanism of RuT was the combination of abrasive wear, oxidative wear. Moreover, the presence of abrasive wear, oxidative wear and fatigue spalling was observed on the worn surface of QT. Wear mechanism was dominated by abrasive wear when the content of ferite was higher, and increased content of pearlite could lead to the change of wear mechanism from abrasive wear to combined action of abrasive wear and oxidative wear due to the severity of oxidation.

Key words: rotational shell, acoustics radiation, semi-analytical method, sound pressure

Abstract: A semi-analytical and semi-numerical method is presented for analyzing the acoustics radiation characteristics of a rotational shell. Combining the dynamics control equation and the sound pressure expression, the vibro-acoustics equation of the rotational shell is formulated firstly. Then, a semi-analytical method is developed based on the superposition principle. The comparisons with the document show that the proposed method is accurate and efficient.

Introduction

Rotational shells are widely used in many engineering fields, such as aircrafts, spacecrafts, submarines and pipelines. The acoustics characteristics of these structures have attracted extensively attention[1]. Because its curvatures are variable in both directions, the dynamic equation of the rotational shell is more complicated than the cylindrical shells. For this reason, the FEM and BEM is the popular method for acoustics radiation analysis of rotational shells. However, it is proved that the numerical method has some disadvantages, i.e., large number of the elements and the poor calculation precision in the higher frequency range, etc. To overcome these shortcomings, this paper attempts to establish the vibro-acoustics equation of the rotational shell and put forward a semi-analytical method to study the acoustics characteristic of rotational shells.

Vibro-acoustics Equation of Rotational Shells

Figure 1 is the geometric scheme of a rotational shell. Under a harmonic external excitation, the displacement and internal force can be expanded with the Fourier series. Performing the dimensionless processions and only taking the symmetric terms for the purpose of simplicities, the displacement and internal force components can be expressed as

$$\xi = \frac{s}{L},\ (u,w) = L\sum_n \left(\overline{u}^{(n)}, \overline{w}^{(n)}\right)\cos(n\theta)\ ,\ v = L\sum_n \overline{v}^{(n)}\sin(n\theta),\ \theta_\varphi = \sum_n \overline{\theta}_\varphi^{(n)}\cos(n\theta),$$

$$S_\varphi = \sum_n K\overline{S}_\varphi^{(n)}\sin(n\theta),\quad M_\varphi = \sum_n (KL)\overline{M}_\varphi^{(n)}\cos(n\theta),\ \left(N_\varphi, V_\varphi\right) = \sum_n K\left(\overline{N}_\varphi^{(n)}, \overline{V}_\varphi^{(n)}\right)\cos(n\theta),$$

where L is the length for dimensionless, K is the membrane stiffness of the rotational shell, n is the circumferential wave number, u, v, w are the displacement amplitudes in φ, θ, z directions at the mid-plane, θ_φ is the rotation of the cross-section in φ direction, $N_\varphi, M_\varphi, S_\varphi, V_\varphi$ are the amplitudes of the membrane internal force, bending internal force, Kelvin-Kirchhoff's equivalent in-plane shear force and transverse shear in unit length of the rotational shell respectively. The variables with "—" stand for relevant dimensionless variables. The superscript n is omitted in the follows for conveniences.

Referring to the approaches in Ref.[2], for a given circumferential wave number n, the dynamics control equation of the rotation shell is

$$\frac{\mathrm{d}\overline{\boldsymbol{y}}}{\mathrm{d}\xi} = \mathbf{g}\overline{\boldsymbol{y}} - \frac{R_\varphi}{K}\boldsymbol{q}, \tag{1}$$

where $\bar{\boldsymbol{y}}=\left\{\bar{u}\ \ \bar{v}\ \ \bar{w}\ \ \bar{\theta}_{\varphi}\ \ \bar{N}_{\varphi}\ \ \bar{S}_{\varphi}\ \ \bar{V}_{\varphi}\ \ \bar{M}_{\varphi}\right\}^{T}$ is the dimensionless state vector of the rotational shell. The coefficient matrix $\mathbf{g}$ is an eight-by-eight matrix, and the expression of each element can be seen in Ref.[3]. $\boldsymbol{q}=\left\{0\ \ 0\ \ 0\ \ 0\ \ \tilde{q}_{\varphi}\ \ \tilde{q}_{\theta}\ \ \tilde{q}_{z}\ \ 0\right\}^{T}$ is the load vector acted on the shell, and R_{φ} is the lame coefficient in the meridian direction.

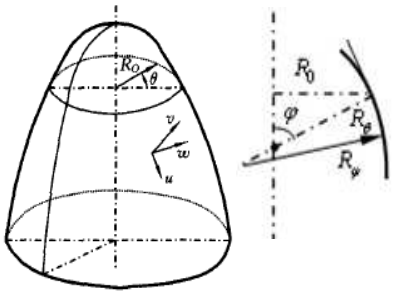

Fig.1 The rotational shell

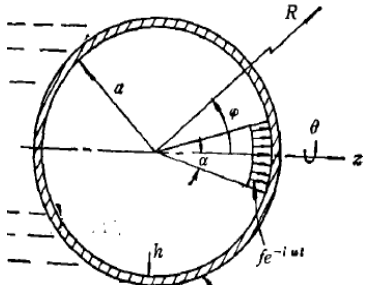

Fig.2 The immersion spherical shell

In Ref.[3], we have derived the expression of the radiation sound pressure as follows:

$$p(P)=\tilde{p}\left(\bar{P}\right)\cos\left(n\theta\right)=\sum_{m=0}^{+\infty}c_{mn}\bar{K}_{mn}\left(\bar{P}\right)\cos\left(n\theta\right),\quad n=\left(0\sim+\infty\right), \tag{2}$$

where c_{mn} denotes unknown coefficients, and the parameter $\bar{K}_{mn}\left(\bar{P}\right)$ is

$$\begin{cases}\bar{K}_{mn}\left(\bar{P}\right)=-\int_{0}^{\pi}\int_{0}^{2\pi}K\left(\bar{P},\varphi_{Q},\theta\right)\cos\left(m\varphi_{Q}\right)\cos\left(n\theta\right)r_{Q}\left(\varphi_{Q}\right)R_{\varphi}\left(\varphi_{Q}\right)d\varphi_{Q}d\theta\\ K\left(\bar{P},\varphi_{Q},\theta\right)=G\left(\bar{P},\bar{Q},\theta\right)=\dfrac{e^{-ik_{0}d\left(\bar{P},\bar{Q},\theta\right)}}{d\left(\bar{P},\bar{Q},\theta\right)}\\ d\left(\bar{P},\bar{Q},\theta\right)=\left[r_{P}^{2}+r_{Q}^{2}-2r_{P}r_{Q}\cos\theta+\left(z_{P}-z_{Q}\right)^{2}\right]^{1/2}\end{cases}, \tag{3}$$

In which, P and Q are coordinates of the field point and source point respectively, $\bar{P}$ and $\bar{Q}$ are the corresponding points on the meridian plane, $d\left(\bar{P},\bar{Q},\theta\right)$ is the distance between point $\bar{P}$ and point $\bar{Q}$.

Substituting Eq.(2) into Eq.(1), the vibro-acoustics equation of a PCLD rotational shell is obtained

$$\frac{\mathrm{d}}{\mathrm{d}\varphi}\begin{Bmatrix}\bar{u}\\ \bar{v}\\ \bar{w}\\ \bar{\theta}_{\varphi}\\ \bar{N}_{\varphi}\\ \bar{S}_{\varphi}\\ V_{\varphi}\\ \bar{M}_{\varphi}\end{Bmatrix}=\boldsymbol{g}\begin{Bmatrix}\bar{u}\\ \bar{v}\\ \bar{w}\\ \bar{\theta}_{\varphi}\\ \bar{N}_{\varphi}\\ \bar{S}_{\varphi}\\ V_{\varphi}\\ \bar{M}_{\varphi}\end{Bmatrix}+\begin{Bmatrix}0\\ 0\\ 0\\ 0\\ \bar{f}_{\varphi}\\ \bar{f}_{\theta}\\ \bar{f}_{z}\\ 0\end{Bmatrix}+\sum_{m=0}^{m_{c}}c_{mn}\begin{Bmatrix}0\\ 0\\ 0\\ 0\\ 0\\ 0\\ \left(R_{\varphi}/K\right)\bar{K}_{mn}\left(\bar{P}\right)\\ 0\end{Bmatrix}, \tag{4a}$$

The above equation can be written as a matrix equation

$$\frac{\mathrm{d}\boldsymbol{y}}{\mathrm{d}\varphi}=\boldsymbol{g}\boldsymbol{y}+\boldsymbol{F}+\sum_{m=-m_{c}}^{+m_{c}}c_{mn}\boldsymbol{p}_{sm}\left(\varphi,m,n\right), \tag{4b}$$

where m_c is the truncated number in the meridian direction, $\overline{f}_\varphi$, $\overline{f}_\theta$, $\overline{f}_z$ are the dimensionless load in φ, θ, z directions respectively, $\boldsymbol{p}_{sm}(\varphi,m,n)=\left\{0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad \left(R_\varphi/K\right)\overline{\overline{K}}\left(\overline{P}\right) \quad 0\right\}^T$ is the generalized sound pressure vector.

The coupling equation Eq.(4) can not be solved for the coefficient c_{mn} is unknown.

Numerical Method

On the juncture of the flow and solid, the Neumann boundary condition is

$$\frac{\partial p(\varphi)}{\partial n}=\rho_0\omega^2 w(\varphi), \tag{5}$$

where n is the unit outward normal vector of the boundary, ρ_0 is the mass density of the fluid media, and ω is the circular frequency of the external excitation.

Based on the superposition principle, the radial displacement of an arbitrary point can be obtained from Eq.(4)

$$w(\varphi)=L\overline{w}_F(\varphi)+L\left[\sum_{m=-m_c}^{+m_c} c_{mn}\overline{w}_{sm}(\varphi)\right], \tag{6}$$

where $\overline{w}_F^{(n)}(\varphi)$ is the Fourier expansion coefficient of the dimensionless radial displacement induced by the external load vector $\boldsymbol{F}$, $\overline{w}_{sm}^{(n)}$ is that induced by the generalized sound pressure load vector $\boldsymbol{p}_{sm}$.

Combining Eq.(2), Eq.(5) and Eq.(6), it is obtained

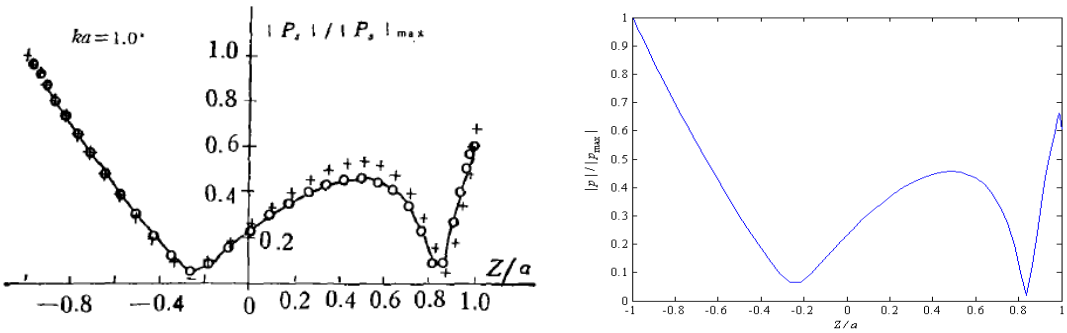
$$\sum_0^{m_c} c_{mn}\left[\overline{\overline{K}}'\left(\overline{P},m,n\right)-\rho_0\omega^2 L\overline{w}_{sm}(\varphi)\right]=\rho_0\omega^2 L\overline{w}_F(\varphi), \quad n=\left(0\sim n_c\right), \tag{7}$$

where the parameter $\overline{K}'_{mn}\left(\overline{P}\right)=-\int_0^\pi\int_0^{2\pi} K'\left(\overline{P},\varphi_Q,\theta\right)\cos(m\varphi_Q)\cos(n\theta)r_Q(\varphi_Q)R_1(\varphi_Q)d\varphi_Q d\theta$, and n_c is the truncated number of the Fourier series.

Setting M_P ($M_P>\left(m_c+1\right)$) distributing points along the meridian of the rotational shell, and calculating the value of $\boldsymbol{p}_{sm}$, $\overline{\overline{K}}'\left(\overline{P},m,n\right)$, $\overline{w}_{sm}(\varphi)$ and $\overline{w}_F(\varphi)$ for each distributing point, M_P equations can be assembled to an algebraic matrix equation as

$$\boldsymbol{A}_n\boldsymbol{c}_n=\boldsymbol{W}_n, \quad n=\left(0\sim+n_c\right) \tag{8}$$

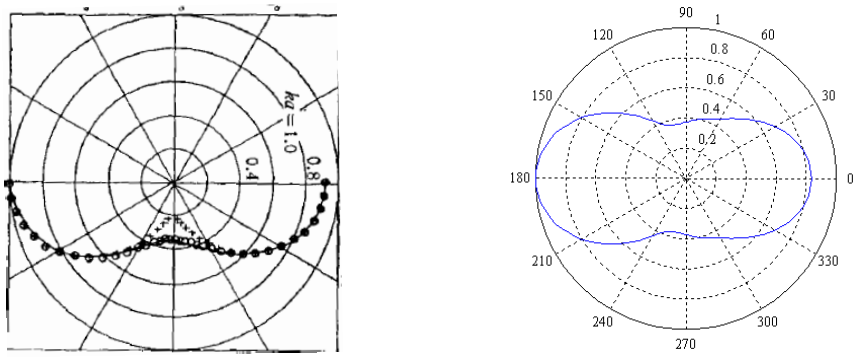
where $\boldsymbol{A}_n$ is the coefficient matrix, $\boldsymbol{c}_n$ is a column vector of the unknown coefficient c_{mn}, and $\boldsymbol{W}_n$ is the displacement vector.



The unknown coefficient c_{mn} can be determined by solving the above equation, then the sound pressure of an arbitrary point is given by substituting c_{mn} into Eq.(2).

Numerical Results and Discussion

In order to invalid the effectiveness of the present method, we consider an immersion spherical shell under a uniform load, as shown in Fig.2. Its geometric and physical parameters are as follows [5]:



$a=1$ m, $h=0.02$ m, $E=210$ GPa, $\rho=7669$ kg/m^2, $\rho_0=1000$ kg/m^2, $c_0=1524$ m/s, $\alpha=32^0$.

The comparisons of the surface and far-field sound pressure between the present method and those in Ref.[4] are shown in Fig.3 and Fig.4. It is seen from figures that the results of the present method is more agreed with the analyzed solution (solid line in Fig.(a)) , which is better than the numerical method in Ref.[4]

(a) Surface sound pressure in document (b) Surface sound pressure in present

Fig.4 Comparison of the surface sound pressure

(a) Far-field sound pressure in document b) Far-field sound pressure in present

Fig.5 Comparison of the far-field pressure

Conclusions

The vibro-acoustics coupled equation of a rotational shell is derived, and a high precision and wide-used semi-analytical method is established in this paper. The numerical results have proved the effectiveness of the present method, which can be extended to the rotational shell with arbitrary shape conveniently. Because it avoids the numerical discretization, the proposed semi-analytical method is more accurate and efficient, and it can be applied in higher frequency range.

Keywords: parabolic trough receiver, RIH, heat loss, emissivity

Abstract. Parabolic trough receivers are a kind of key components of a solar trough power plant, which absorb and transfer the high flux solar energy to the heat transfer fluid flowing in it. A Receiver Impedance Heating (RIH) method is put forward by analyzing the inadequacies of traditional methods. Voltage is imposed on both ends of the receiver and then the receiver is self-heated via a large electrical current flowing through it based on the Joule Effect. Once the receiver reaches a thermal equilibrium the product of voltage imposed on the receiver and electrical current flowing through the receiver is equal to the heat loss of the receiver to ambient environment at corresponding temperature difference of receiver temperature above ambient. The experiment system is simple, low-cost, and easy to operate. Experiment results show that curve of heat loss is smooth and measurement uncertainty is low, which means accuracy of the experiment results is high, while time period to reach a thermal equilibrium at every absorber temperature reduces to 2-3hours which is one fifth of that needed in traditional methods.

Introduction

Parabolic trough receivers are a kind of key components of a solar trough power plant. Receivers convert the incoming solar radiation into high temperature heat and transfers it to the heat transfer fluid flowing in it while losing thermal energy to ambient in combination of conductive, convective and radiative energy through the vacuum space and support brackets when the collector is on focus. Usually emissivity of selective coating on outer surface of an absorber, geometry of glass envelops and glass-metal sealing, vacuum condition in annular space, and other properties have strong influences on receiver's thermal performance [1][2][3][4][5]. So it is very important for the buyers and sellers to know the thermal performance of a parabolic trough receiver.

Generally there are two principles to quantifying the heat loss of a receiver [1][5]. One is the quasi-steady-state equilibrium. Larger parabolic trough collectors, heat transfer fluid and other devices are necessary according to this principle, which is complicated to operate and costs very much. Another is the steady-state equilibrium. In this way a heat source brings the receiver to a test temperature. The whole receiver ideally has a uniform temperature on the surface of the absorber. The power required to maintain the receiver in steady-state equilibrium is equal to the heat loss at some absorber temperature. DLR employed a 4m long quartz heater to supply thermal energy for the test stand of parabolic trough receivers [5]. The heater is coaxially inserted inside a tubular copper pipe which is used to uniform the temperature field of the quartz heater and then to heat the receiver uniformly as much as possible. 14 thermocouples are employed to measure the temperatures of receiver, glass envelop and ambient respectively. The maximum heating power of the heater is 5.9KW. The time to reach steady state equilibrium is from 5 to 24hours depending on the heating

power, when temperature changes less than 1.0℃ within one hour. NREL erected a similar test system to evaluate the thermal performance of parabolic trough receivers based on the steady state equilibrium and electrical heating, which employ 6 heaters and corresponding temperature controllers [5]. Maximum heating power of the test system is 9.0KW and the time to reach steady state equilibrium is from 12 to 24hours depending on the heating power. Then some tests have been carried out by the test system [7][8]. In addition, there are some similar test systems based on the same principle and electrical heating in China [1].

Due to the existing problems in above test systems a novel test system based on receiver impedance heating (named RIH) and steady state equilibrium is presented to reduce the time period of reach steady state equilibrium and to improve the temperature uniformity on absorber surface.

Experimental Setup

Experiment System Description

Based on the steady state equilibrium and Joule affect of metal an experimental system has been established while receivers serve as impedance, which is named as receiver impedance heating (RIH) method.

The experiment system is made up of three receivers, a regulated power supply, a current transducer, a MCU data acquisition unit, touch screen and several thermocouples. Fig. 1 and Fig. 2 show the schematic diagram and picture of the experimental system based on the RIH method respectively.

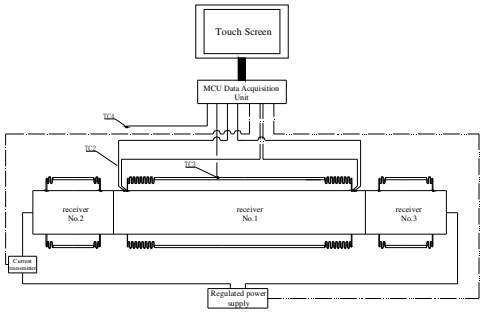

Fig. 1 Schematic Diagram of the Experimental System based on the RIH Method

Fig. 2 Experiment System Established based on the RIH Method

Three receivers are welded in line to form a receiver group via stainless-steel welder protected by argon, where the centered receiver No.1 is the test target. Two power cables with a cross-section of 100mm2 serve to connect two ends of the receiver group respectively with Regulated power supply to form a closed circuit. A current transmitter(typed CHZ 500G, Accuracy: ±0.5%) traversed by one power cable serves to measure the current flowing through the receiver and puts out a analog voltage signal in the range of 0 to 5V collected by MCU data acquisition unit. Voltage imposed on the inner part of receiver No.1 is collected directly by connecting welding locations where the absorber joints with the bellows, and the MCU data acquisition unit connected with data cables. Four thermocouples (Type K, Class II) are used in the test system. Two of them serve to measure absorber temperature,

and the other two serve to measure the glass envelop temperature and ambient temperature. A MCU data acquisition unit and a touch screen serve to acquire, monitor and save the data collected. All the thermocouples are calibrated in advance. Parts of receiver exposed to ambient should be insulated with a mineral wool of 150mm thickness before conducting the experiments.

Experiment Principles

Because of the uniform wall thickness, current flowing through the receiver will generate a uniform temperature field along the axis direction and the circumferential direction on the absorber wall based on the famous Joule affect of current. Temperature gradient does not exist in theory. Therefore, one thermocouple is attached to the outer surface of the absorber of receiver No.1, which is enough for the absorber temperature. Likewise one thermocouple is enough for glass envelop temperature and the ambient temperature respectively. Two thermocouples are fixed on each end joint of the absorber of receiver No.1 by spot welding. The thermocouple for glass envelop temperature is attached to the outer surface of the glass envelop. The thermocouple for ambient temperature is placed in an opened carton which is more than 1.0 meter far away from the receiver group. By setting different output voltage of the power supply in the touch screen the receiver group will reach different steady-state equilibrium of energy. Electric power exhausted depends on absorber temperature and the thermal performance of the receiver. Time period that the receiver group reaches steady state equilibrium of energy is defined by temperature fluctuation of less than ±0.2K within one hour. Experiment results show that average time period is around 2 hours to reach steady state equilibrium of energy.

Data Processing

Absorber temperature, glass envelop temperature, ambient temperature, electrical current, voltage and receiver length inside vacuum space of receiver No.1 are expressed with T_1, T_2, T_0, V, I and Labs, then absorber temperature T_1 minus ambient temperature T_0 is equal to the temperature difference $\Delta T10$ of absorber above ambient, while absorber temperature T_1 minus glass envelop temperature T_2 is equal to Temperature difference ΔT_{12} of absorber above glass envelop. For each steady state equilibrium of energy total heat loss of receiver No.1 is equal to production of the current flowing through the receivers and the voltage exerted. Heat loss per meter q_T can be expressed with eq. 1,

$$q_T = VI / L_{abs} . \tag{1}$$

Assuming that the absorber is a blackbody included in a big closed cavity, the selective coating emissivity ε can be calculated by eq. 2,

$$\varepsilon = q_T / \left[\pi D_{abs} L_{abs} \sigma \left(T_1^4 - T_2^4\right)\right]. \tag{2}$$

Where, Dabs is the outer diameter of absorber and σ is the Stefan-Boltzmann constant.

Via eq. 1 and 2, Heat loss per meter and the selective coating emissivity at different work temperature can be obtained. Then performing polynomial fitting Experimental correlations between q_T and ΔT_{10}, between q_T and ΔT_{12}, and between ε and ΔT_{10} can be correlated. Comparing the heat loss per meter at same temperature difference and selective coating emissivity of different receivers at same absorber temperature you can easily evaluate the thermal performance of difference receivers quantitatively. The lower the heat loss is at the same temperature difference, the better the thermal performance of a receiver is. And the lower the emissivity is the better the thermal performance of the selective coating is.

Results Discussion

Two receivers tested in this paper are from our cooperation. The receiver is 4060mm long, 70mm in absorber diameter and 115mm in glass envelop diameter. Receiver 1# has been working for two year at maximum temperature around 350 ℃ and receiver 2# is a new one, which are chose at random

from the same batch of products. Ambient temperature is around 20 ℃. Absorber temperature is in the range of 150 to 450 ℃ with an interval of 50 ℃.When fluctuation of absorber, glass envelop and ambient temperature is in the range of ±0.2 ℃ while fluctuation of voltage and electrical current is in the range of 0.05 V and 0.25A respectively during one hour, receiver group are thought of reaching a steady-state equilibrium. Experimental results are shown in fig. 3 to fig. 6.

Fig. 3 shows the heat loss change with temperature differenceΔT_{10}. From fig. 1 we know that the heat loss curves from receiver 1# and receiver 2# are very smooth, which indicate precision of the experiment data is very high. Heat loss of receiver 1# is higher than that of receiver 2# apparently, which means thermal performance of receiver 2# is better than that of receiver 1# and thermal performance of a new receiver reduced after a year of operation.

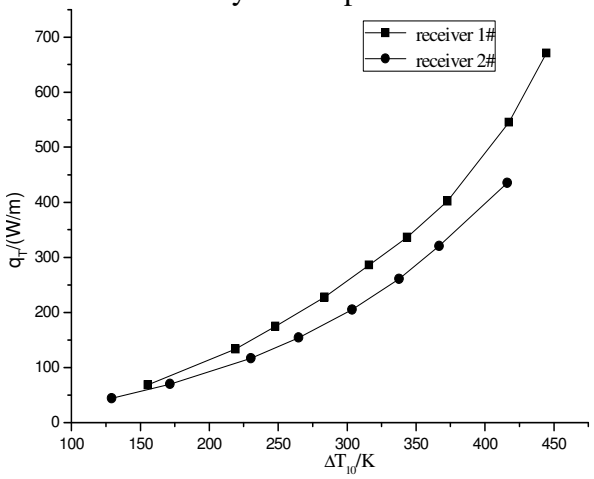

Fig. 3 Heat Loss Change with Temperature Difference ΔT_{10}

After the experiment we find coating became red and getter became white and smaller. We think that aging of selective coating and reduction of vacuum level in annular space cause the thermal performance reduction of receiver 1#.

Experimental correlation of receiver 2# by polynomial fitting is as eq. 3:

$$q_T = -65.04 + 1.3462\Delta T_{10} - 6.13\times10^{-3}\Delta T_{10}^2 + 1.89193\times10^{-5}\Delta T_{10}^3 - 1.20563\times10^{-8}\Delta T_{10}^4 . \quad (3)$$

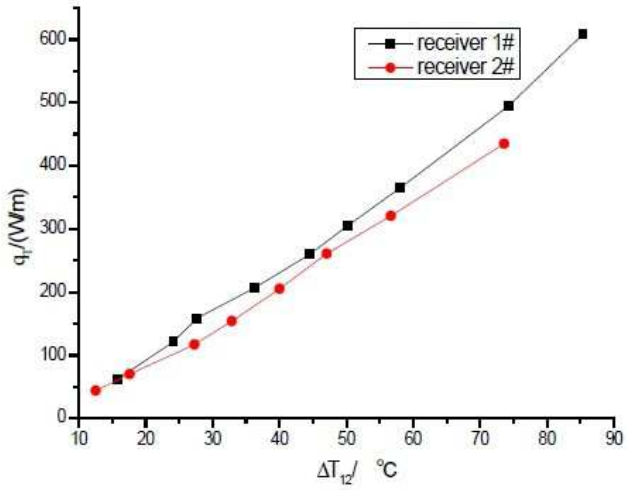

Fig. 4 Heat Loss Change with Temperature Difference ΔT12

Fig. 4 shows the heat loss change of receiver 2# with temperature difference ΔT_{12}. Its experimental correlation by linear fitting is as follows:

$$q_T = -49.65 + 6.513\Delta T_{12} . \quad (4)$$

This correlation is almost a straight line (R^2=0.99539). So as an alternate we can also make evaluation qualitatively by comparing the slop of two straight lines: the larger the slop is, the higher the heat loss is.

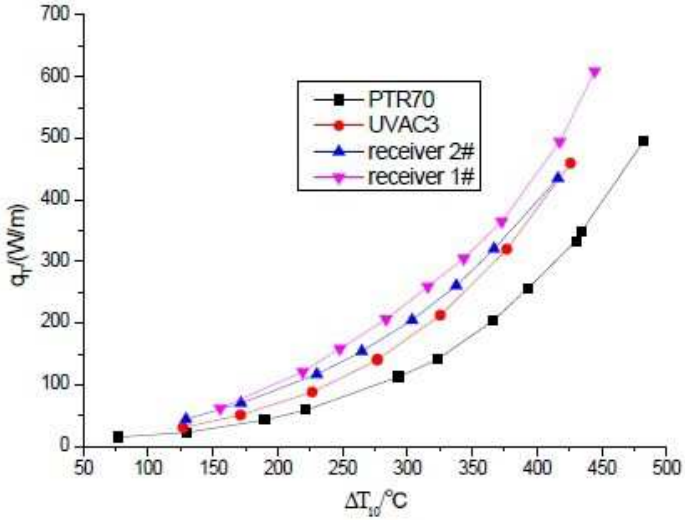

Fig. 5 Comparison of Heat Loss Curves from the Novel System and the Traditional System [7][8]

Fig. 5 shows the comparison of experiment data with that in literature data. Fig. 5 indicates heat loss of receiver 1# and receiver 2# is higher than that of PTR70 and UVAC3, but heat loss curves of receiver 1# and receiver 2# are smoother than that of PTR70 and UVAC3 generally, which validates the feasibility and Reliability of RIH method put out above.

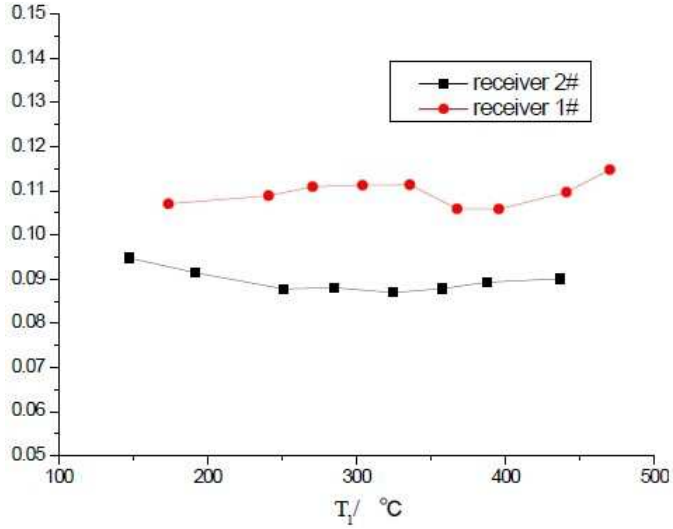

Fig. 6 Emissivity of Solar Selective Coating Change with Receiver Temperature T1

Fig. 6 shows the selective coating emissivity changes of receiver 1# and 2#. We know, from fig. 6, that coating emissivity of receiver 1# is higher than that of receiver2#, which confirms the aging of selective coating and explains the heat loss increase after a year of operation at the temperature over 350 ℃. In addition, coating emissivity reduces first and then increases generally, which are consistent with that in literature [7],[8]. But the curves' trends in fig. 6 don't meet the general law that the selective coating emissivity on outer surface of absorber increases with the increase of absorber temperature. We think it is probably the measurement error of temperature difference ΔT_{12} of receiver above glass envelop that causes a calculation deviation of selective coating emissivity. From eq. 2 we have

$$\varepsilon = q_T / \pi D_{abs} L_{abs} \sigma \left(T_1^2 + T_2^2\right)\left(T_1 + T_2\right)\left(T_1 - T_2\right)^{-1}. \quad (5)$$

In eq. 5 the item (T_1+T_2) and the item (T_{21}+T_{22}) are the sum of absolute temperatures and the sum of square of absolute temperatures respectively. However the item (T_1-T_2) is the temperature difference of absolute temperatures. So a small deviation in item (T_1-T_2) will cause a very large

fluctuation in the value of the selective coating emissivity, especially in lower value of the item (T_1-T_2). Moreover, measurement error of absorber length L and outer diameter will also have some influence on selective coating emissivity. In addition, Thermal contact resistance caused by fixation of temperature sensor on absorber and glass envelop, and fixation locations of temperature sensors on absorber will have influence to some extent. Further work will be done to perfect this experimental system and more receivers will be tested in follow-up experiment.

Uncertainty Analysis

Measurement Uncertainty is the root of sum of squares of total bias uncertainty and total precision uncertainty, while Total bias uncertainty and total precision uncertainty are computed by eq. 6 respectively [9]. Precision uncertainty of each independent variable is expressed in Standard deviation of the mean, expressed as eq. 7, while bias uncertainty of each independent variable is calculated according to the uniform distribution, expressed as eq. 8.

$$U_f = \sqrt{\sum_{i=1}^{n} (\partial f / \partial u_i)^2 \Delta u_i^2} \ . \tag{6}$$

$$u_{pre} = \sigma_x / \sqrt{n} \ . \tag{7}$$

$$u_{bias} = a / \sqrt{3} \ . \tag{8}$$

Where, U_f is the uncertainty of function f, u_{pre} is the uncertainty of random error of variable x, n is the number of measurements, σx is the standard deviation of variable x, the letter a is the systematic errors of equipments, and u_{bias} is the uncertainty of systematic errors of equipments.

For the above experiment system calculation of heat loss of the receiver is independent with temperature, shown as eq. 2. Experiment uncertainty of heat loss and temperature should been computed respectively. For electrical current transmitter the variable a is equal to 0.5% of the measuring value. For thermocouple on the absorber, glass and ambient temperature the variable a is equal to 0.0075 of the measuring value, 2.5 ℃ and 2.5 ℃.

Assuming that Measurement uncertainty of length L of the absorber is neglectable. According to eq. 6-8, the maximum measurement uncertainties of heat loss, temperature difference of absorber above glass envelop, temperature difference of absorber above ambient, and emissiveity of selective coating are shown in table 1.

TABLE 1 MAXIMUM MEASUREMENT UNCERTAINTY

Max uncertainty	Receiver 1#	Receiver 2#
$U_{\Delta T1}$[℃]	4.3	4.1
$U_{\Delta T2}$[℃]	4.3	4.1
$U_{heatloss}$[W/m]	1.9	1.4
U_ε	0.0051	0.0055

Measurement uncertainties of emissivity of selective coating at different temperature respectively are shown in fig. 7.

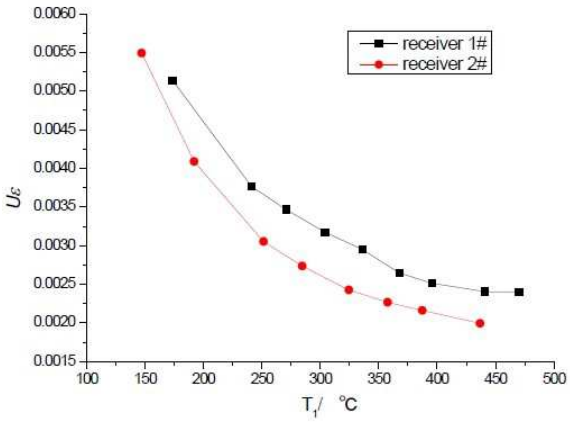

Fig. 7 Selective Coating Emissivity Changes at Different Receiver Temperature

Fig. 7 shows that measurement uncertainty of selective coating reduces with the increase of receiver temperature. Maximum measurement uncertainty of selective coating is up to 0.0055 which causes a high influence on the emissivity of selective coating and so explains why the emissivity curves in fig. 6 reduces first and then increases.

Conclusions

A novel experiment system, named RIH, has been developed to evaluate the thermal performance of parabolic trough receivers, which employs receiver impedance heating based also on the steady state equilibrium. A uniform temperature is formed along both the axial and circumferential directions on receiver surface in this way. Via the novel system RIH developed heat loss of parabolic trough receivers is measured and then the selective coating emissivity is calculated at different absorber temperature levels. Experiment results show that heat loss curves are very good and selective coating emissivity is reasonable. Uncertainty calculation shows that uncertainty of heat loss is very low while uncertainties of temperature and selective coating emissivity at low receiver temperature are very high, which causes high influence on the selective coating emissivity, especially at low receiver temperature.

Keywords: fragments; numerical simulation; LS-DYNA; damage efficiency

Abstract: By means of theoretical calculation and LS-DYNA, fragments weight distribution law, fragments velocity and fragments distribution, fragments motion law and static dispersion range are compared. The two results are basically consistent. Analysis result proves that penetration-explosion warhead can form greater bound of valid fragment cluster.

Introduction

When projectile explodes, the projectile forms plenty of with high velocity fragments which damage martial personnel and equipment and device around. Fragment kill elements demolish targets structure and weaken targets strength by means of high-velocity bump and penetration, which make targets lose partial or all functions. Natural fragments formation is divided into four steps, which connects with the axial expansion of projectile shell.

Projectile explosion is a highly nonlinear course of transient dynamics state, concerned with impact dynamics, structural dynamics, fluid dynamics and fluid-structure interaction etc. It is hard to gain complete result of damage effect by means of purely theoretical calculation. With theoretical calculation and numerical simulation, damage effect is analysed comprehensively, which provide basis for applications of penetration-explosion ammunition.

Theoretical calculation of fragments damage effects

Fragments weight distribution law

Projectile explosion produces detonation outcome which acts on projectile body. Projectile body expands fast. When warping reach certain level, projectile body first forms slight crackle at the most weak link place and enlarge step by step. Because detonation outcome continues on acting, projectile body warping increases gradually, then projectile body produces new slight crackle continuously. After slight crackle intersects each other, projectile body forms fragments. Penetration-explosion warhead produces plenty of fragments with certain weight, fragments weight is controlled by means of shell crystalloid size and thickness, fragility, tenacity as well as dynamite pack type.

（1）Natural fragments total quantity N_0

$$N_0=\frac{m_s}{k^2 t_0^{5/3} d_i^{2/3}(1+t_0/d_i)^2} \quad (1)$$

In formula, m_s shell weight, t_0 shell thickness, d_i shell inner diameter, k rest on detonator coefficient.

（2）Fragments weight distribution $N(m_f)$

$$N(m_f)=N_0\exp[-(\alpha m_f/u)^{\lambda}] \quad (2)$$

In formula, α is constant, λ is experiential constant, thin projectile body λ=1/2 ($\alpha=2$), thick projectile body λ=1/3 ($\alpha=6$).

Fragments velocity and velocity distribution

Penetration-explosion warhead damage effect closely related to the factors of fragments initial velocity, fragment weight, valid fragments quantity, shape of fragments, the dispersion angle and direction angle etc. Warhead expands and warps fast under detonation outcome acting, so fragments have very high velocity. Fragments acceleration reduces gradually as detonation outcome leaks from body crack. When the mutual balance of air resistance and detonation outcome acting on fragments, the velocity of fragments reaches biggest value, this velocity is named of original velocity. Fragments original velocity usually is up to 600~2000 m/s.

The major factors that affect fragments original velocity include detonator pack type, pack restraint and shell material. Now in the point of kinetic energy, various theoretical calculation methods of fragments original velocity have been established in the basic expression of kinetic energy. For warhead in cylindrical detonator pack, the most general formula of fragments original velocity is Gurney formula:

$$v_0=\sqrt{2E}\sqrt{\frac{\beta}{1+\beta}} \quad (3)$$

In formula, $\sqrt{2E}$ is detonator constant, each kind of detonator has certain Gurney constant, it relates to loading density and other factors. $\beta=m/M$, m is detonator weight, M is shell weight. This formula is based on assumption that fragments owned the same original velocity, without consideration of the influence of axial sparse wave in instant detonation. The formula applies to cylindrical warhead original velocity calculation, with the ratio of length to diameter $L/D>2$, the ratio of shell to detonator weight $0.2\le\beta\le0.3$ and the same body thickness. Because of the assumption of instant detonation, the formula only figures out approximation of the biggest velocity, the velocity distribution can not be calculated by virtue of the formula. The calculation result only reflects that the performance of detonator, pack type and the ratio of shell to detonator weight affect fragments original velocity, but the influence of other structural parameter is ignored outright.

About fragments velocity distribution according to detonator pack axis, Randers has studied the influence of end effect on original velocity distribution, and put forward the correction Gurney formula.

$$v_x=\sqrt{2E}\sqrt{\frac{F(x)\beta}{1+0.5F(x)\beta}} \quad (4)$$

Here, $F(x)$ is correction coefficient on end flight and dispersion of Gurney relation, its expression

$$F(x)=1-[1-\min(\frac{x}{2r},1.0,\frac{l-x}{r})]^2 \quad (5)$$

In formula, x is the distance of fragments to benchmark end, priming end is benchmark end (m), r is detonator pack radius (m), l is detonator pack length (m), v_x is fragments original velocity of x position (m/s).

Static flight dispersion range of fragments

The dispersion angle and direction angle are the two most important factors to destroy target among fragments dispersion parameter. Warhead fragments dispersion angle is shown as Fig.1. Compared with fragments fight range, the length and diameter of warhead are very little, which can be neglected. In practice, warhead fragments dispersion angle is defined, shown as Fig.2. Because of the influence of end effect, fragments density of dispersion angle edge is lower. The dispersion angle, used for damage efficiency calculation, is equal to the angle that the effective occupancy space where fragments distribution density accords with requirements. The dispersion angle is accustomed to the angle of space taken by effective 90% fragments.

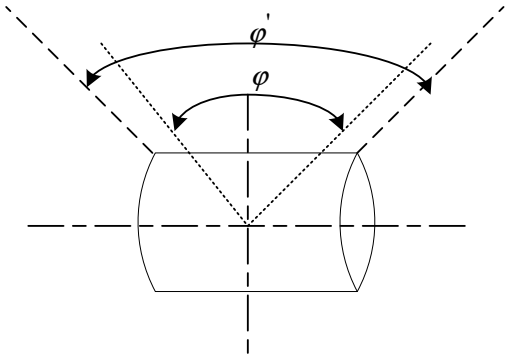

Fig.1 Fragments Dispersion angle

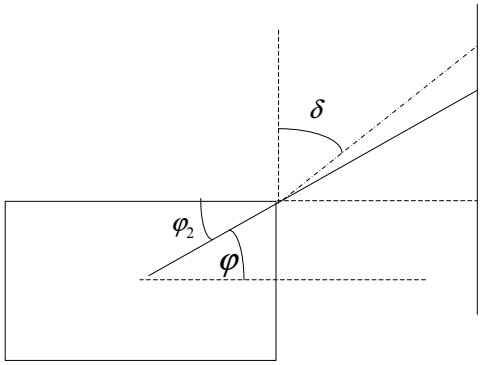

Fig.2 Relation of Angles

The number of penetration-explosion warhead explosion initiation position is limited, fragments will deviate normal direction when thrown out. Taylor formula is a classical formula used for calculation dispersion direction. In 1941 G. E. Taylor put forward experience formula, when Taylor was researching on that metal medium (plain plate or round pipe) is driven by detonator. The Taylor formula extensively applied in project field, its specific form is $\delta=\arcsin\left(\frac{v_0}{2D}\cos\phi_2\right)$.

In formula, δ is the angle between dispersion direction and shell normal, v_0 is fragments original velocity (m/s), D is velocity after detonator explosion (m/s), ϕ_2 is the angle between explosion initiation position to some shell dot shell, the angle between x-axis and the normal of this point on the detonation wave surface. The relation between angles is shown as Fig.2.

δ is converted into the angle between dispersion direction and warhead axis, $\varphi_0=\frac{\pi}{2}-\delta-\gamma$.

In formula, γ is the angle between projectile axis and shell bus, when shell is cylindrical, $\gamma=0$.

Numerical simulation of fragments damage effects based on LS-DYNA

The basic thought of finite element analysis is that the more simple problem replaces complex problem, then solve the more simple problem. Since most actual problems are hard to get accurate solution, nevertheless finite element analysis not only calculate precisely but also apply to complex shapes, so FEA has become an effective project analysis mean. Now, large scale commercial FEA software includes ANSYS, ADINA, DYNA-3D, AUTODYN and CTH etc. LS-DYNA is chosen as research means for numerical simulation of penetration-explosion warhead fragments damage.

Penetration-explosion warhead holds plane symmetrical character, which could be simplified into 1/4 model for calculation. Model is divided with entity unit, symmetrical restraint condition is exerted at symmetrical boundary. The method of fluid-structure interaction is chosen to accurately describe detonation course and the interaction of shell and detonation wave. In model air medium and detonator pack are partitioned into Euler unit, shell and end cover are partitioned into Lagrange unit. In this model, air and detonator grid are partitioned into 987,684 units. After shell breakage, erosion contact algorithm is adopted to control mutual collision between fragments. In the calculation course, numerical model is simplified and installed as follows, gravity role and air stickiness are neglected, initialization of air grid boundary is 1 atm to prevent air weight escape, seepage control is carry out for fluid-structure interaction to maintain conservation of energy.

In calculation model, the major packs dynamite is B dynamite, density is 1.7 g/cm3, explosion velocity is 7900 m/s, CJ pressure is 29 GPa. Shell and end cover material density are 7.8 g/cm3, elastic modulus is 210 Ga, Poisson's ratio is 0.3, yield strength is 245 MPa, all parameters are described by MAT_PLASTIC_KENEMATIC model. As far as the development performance of material change under explosion load, this model has considered the influence of strain rate effect.

Comparison and analysis of the result based on calculation and simulation

Penetration-explosion warhead fragments damage effect is analysed with theoretical calculation and numerical simulation, the result of theoretical calculation and numerical simulation is consistent on the whole. The dispersion angle of fragments is shown as Fig.3. The original velocity distribution of fragments is shown as Fig.4. The quantity dispersion of fragments is shown as Fig.5 according to weight.

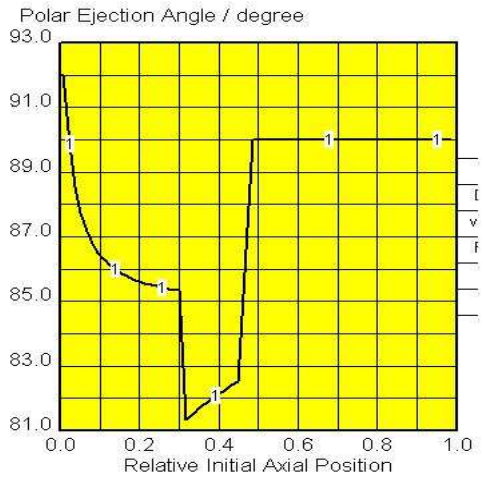

Fig.3 Dispersion angle of fragments

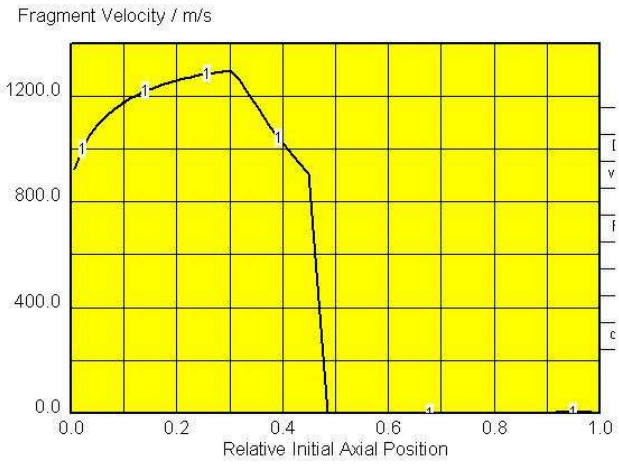

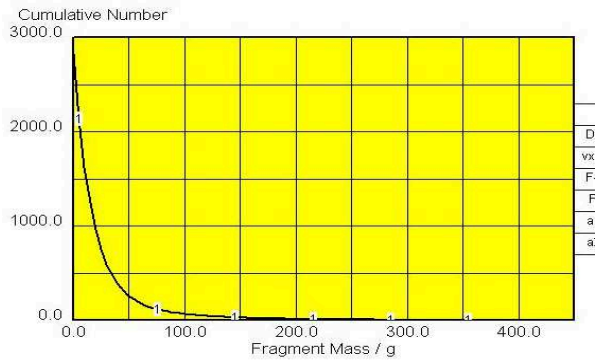

Fig.4 Original velocity distribution of fragments

The summary can be found out from result of calculation and simulation. The dispersion angle of fragments is between 81°and 92°, The original velocity distribution of fragments is from 900m/s to 1300m/s, the velocity at warhead bottom is higher than other part. At warhead peak, Fragments don't exist because of scarcity of detonator. From fragments quantity and weight distribution, the total quantity of fragments is up to 2910 pieces, fragments average weight is about 22g.

Conclusion

The quantity, weight and velocity distribution, dispersion direction and kinetic energy of penetration-explosion warhead fragments are researched based on theoretical calculation and numerical simulation, the analysis result proves that the weight and velocity distribution, dispersion direction of penetration-explosion warhead fragments are efficient to damage targets, which can form larger area of effective fragments.

Keywords: Brake-by-wire, MR Brakes, Self-energizing, Wedge Mechanism, Torque Analysis

Abstract. Brake-by-wire system is a new concept of brake system using electromechanical actuators instead of conventional hydraulic actuators. It is more compact, more efficient and responses faster than traditional brake systems. Magneto-rheological (MR) fluid is widely used due to its outstanding properties. In this paper, an MR based Brake-by-wire system with self-energizing capability were proposed and designed. It combined a typical single-disk-type MR brake with a wedge mechanism for self-energizing purpose. According to the torque analysis of the proposed MR brakes, the brake torque was significantly amplified. This research work presented a promising brake actuator, which allows MR fluids to be applied in automotive Brake-by-wire systems.

Introduction

MR fluids are suspension of micron sized magnetic particles dispersed in non-magnetic liquids. They behave as Newtonian Fluids in the absence of an external magnetic field. However, when a magnetic field is exerted to the MR fluids, they will turn into Bingham Fluid in milliseconds. This process is reversible, continuous and repeatable. Moreover, the yield shear stress of the MR fluids can be precisely controlled by adjusting the intensity of the magnetic field. Due to these favorable properties, MR fluids are widely used in areas such as dampers, clutches, valves, brakes, biological assistant devices, building constructions etc.

MR brakes are an important branch among these applications. Since they can be precisely controlled by electric signals, they are promising to be adopted as Brake-by-wire system. However, the brake torque generated by MR brakes is normally too small to be applied in vehicles. Recently there are mainly three categories of measures to increase the brake torque. The first category is to change the structure of the rotor. For example, multiple-disk-type MR brakes were widely tested and could generate much larger brake torque than single-disk-type MR brakes [1,2]. Other researchers verified the form of the rotor from disk-type into drum-type, including the so-called T-shape drum-type brake [3,4]. It has also been proved that changing the formation at the end of a brake disk can also increase the brake torque, such as using a wave form disk [5] or a disk with circular cuts at the end [6]. The second category can be summarized as changing the layout or size of the coils [7,8,9]. The last category utilized the property of the MR fluids that its shear yield stress will be significantly enlarged under compression [10]. Therefore, the brake torque can be improved either by the compression from the radial direction or axial direction [11]. For this purpose, extra components which provide the compression force need to be added to the brake device.

The common drawbacks of the first two categories of measures are the complexity of the structure, resulting in the difficulties during manufacturing, assembly and more heat will be generated during braking, which is unfavorable for the working efficiency of MR fluids. In terms of the third category, how to precisely control the desired brake torque coordinated with the

compression force is tough to handle. This paper presented an automotive MR based Brake-by-wire system with a simple structure and easy to be controlled. It combines a single-disk-type MR brake with a self-energizing wedge mechanism, which helps significantly increase the brake torque. Moreover, it can cooperate with regenerative braking, thus to save certain amount of energy.

Operational principle of typical single-disk-type MR brakes

A disk-type or drum-type rotor is common used in MR brakes. In this paper, a single-disk-type MR brake is chosen since it is more compact and thus easier to be combined with the wedge mechanism. As shown in Figure 1, it mainly consists of housing, coil, rotor plate, bearing, shaft and seal rings. The MR fluids fill in the sealed working gap between the housing and the rotor plate.

Under normal driving conditions, when no braking demand is raised, no current will be applied to the coil. The rotor plate as well as the shaft rotates almost freely in the MR fluids, only with a small resistance torque caused by the Newtonian viscosity of the MR fluids. When a braking action is demanded, certain amount of current corresponds to the desired brake torque will be applied to the coil. Then the MR fluids transform promptly into solid-like form thus providing the desired brake torque to the rotor plate. Fig. 2 shows the microstructure of the MR fluids with or without the effect of an external magnetic field. Under the external magnetic field, the MR particles will form promptly chains between the stator and rotor. The resistance torque will mainly caused by the deformation or destruction of these chains due to their relative motions. Since the change of yield shear stress of the MR fluids is corresponding to the intensity of the magnetic field, the generated brake torque can be precisely controlled by adjusting the magnitude of the applied current.

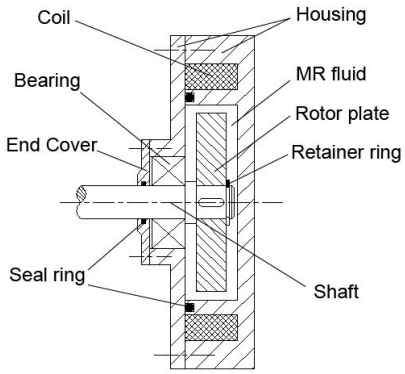

Fig. 1 Structure of single-disk-type MR brakes.

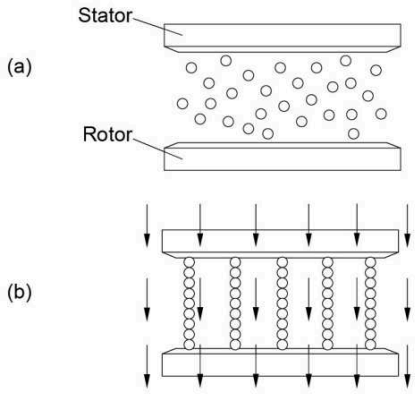

Fig. 2 Microstructure of MR fluids (a) without or (b) with external magnetic field.

Operational Principle of a wedge mechanism with self-energizing capability

Electric Wedge Brakes with self-energizing capability were firstly proposed and several generations of prototypes have been developed by Siemens VDO [12]. The self-energizing is realized by a wedge mechanism. As shown in Fig. 3, operational principles of a conventional brake and a wedge brake are presented on the left and right side, respectively. It is obvious that the normal force to the brake lining of the conventional one is equal to the input force, while in the wedge brake, the normal force will be largely increased due to the wedge mechanism, as expressed by Eq. 1 and Eq.2, respectively.

$$F_b = \mu \cdot F_I \tag{1}$$

$$F_b = F_I \cdot \frac{\mu}{\tan\alpha - \mu} \tag{2}$$

where F_b and F_I are the brake force and input force, respectively, μ is the friction coefficient and α is the angle of wedge.

As can be figured out from Eq. 1 and Eq. 2, no input force will be needed under the optimal condition when $\tan\alpha$ is equal to μ. Nevertheless, since the friction coefficient μ will change during the braking process, the wedge mechanism is not really able to work under an optimal condition. Moreover, an input force from an opposite direction will be required to pull out the moving wedge if the friction coefficient μ changes to a value which is larger than $\tan\alpha$. In principle, a certain amplification factor can be obtained by coordinating the displacement of the wedge and the input force according to the change of friction coefficient. In this way, an amplified brake torque can be achieved as long as a certain input force is exerted to the moving wedge.

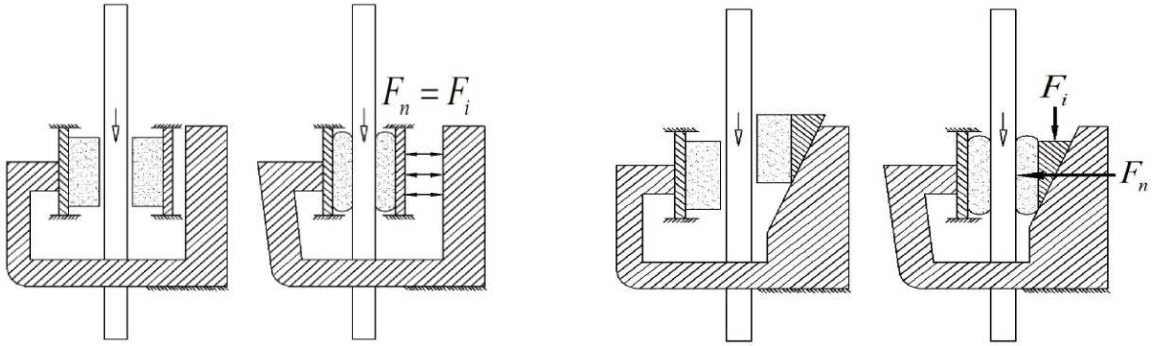

Fig. 3 Schematic of conventional brakes (left) and wedge brakes (right).

Design of MR brakes with self-energizing capability

The configuration of the proposed MR brakes is shown in Fig. 4. In general it combines an MR brake part with a wedge mechanism together. The inner structure of the MR brake part was already presented in the second section of this paper. Unlike typical MR brakes, the rotating shaft of the MR brake part here is not the driving shaft, instead it is parallel to it by applying a gear pair. The rotor plate inside the housing rotates synchronously with the driven gear. The housing of the MR brake part is not fixed and will rotate together with the inner rotor plate when current is applied to the coil and the MR fluids turn into solid-like state. As shown in Fig. 5, the torque of rotation of the housing will be transformed onto the moving wedge via a connecting rod, which connects the housing and the moving wedge on both ends respectively using ball joints. A return spring fixed on the car body is used to provide a counter force to the wedge mechanism. Particularly there are rollers amounted between the moving wedge and the stationary wedge so as to reduce the frictional resistance between them. The brake lining is fixed on the moving wedge and can move together with it towards the brake disk to perform a brake action. Moreover, a flat generator is connected to the driven axle for regenerative braking purpose, which enables regenerative energy recovery, thus electric energy can be saved.

The operational principle is easy to be understood. Under normal driving conditions, no current is applied to the coil and thus there is no displacement of the wedge mechanism. The driving shaft as well as the rotor plate inside the MR brake part rotates almost freely. When a brake action is

demanded, certain amount of current is conducted through the coil according to the brake signal, resulting in the rheological effect of the MR fluids. The housing will then rotate together with the inner rotor plate, pushing the moving wedge via the connecting rod against the stationary wedge, thus exerting the desired brake force onto the brake disk. During this brake process, regenerative braking is involved with the help of the generator, thus certain amount of energy can be saved.

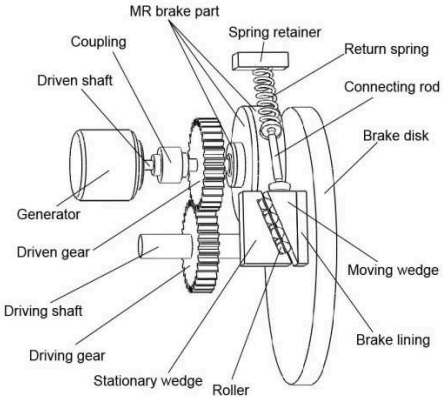

Fig.4 Structure of the proposed MR brakes

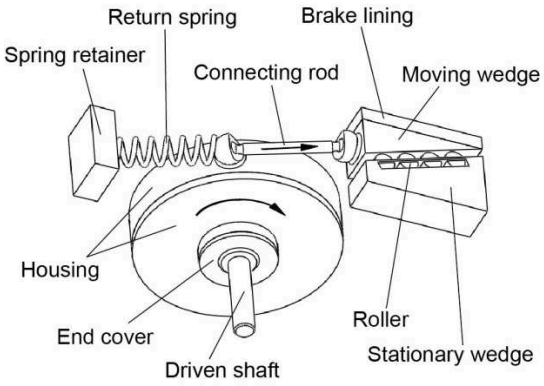

Fig. 5 Structure of the force transform mechanism

Torque analysis of MR brakes with self-energizing capability

Torque analysis of the proposed MR brakes can be separated into the following two parts: (1) relationship between rotating torque of the housing and the input control current, (2) relationship between the rotating torque of the housing and the input force of the wedge mechanism. Moreover, with the Eq.2 above we can easily obtain the amplification of the torque and the relationship of the desired brake torque and input control current.

The brake torque model of a typical single-disk-type MR brake was already established by many researchers [11,13]. Fig. 6 shows the design parameters of such an MR brake. By applying the Bingham Model, the relationship between the brake torque and the yield shear stress of MR fluid can be expressed in Eq. 3:

$$T = \frac{4}{3}\pi\tau_{yd}\left(r_o^{\,3} - r_i^{\,3}\right) + \frac{\pi\eta\omega}{h}\left(r_o^{\,4} - r_i^{\,4}\right) \tag{3}$$

where r_i and r_o are inner and outer radii respectively, τ_{yd} is the yield shear stress, η is the off-state viscosity of MR fluid, ω is the rotational speed of the rotor plate, and h is the gap thickness.

In addition, the relationship between the yield shear stress of MR fluid and the input control current can be derived from Eq. 4 and Eq. 5 as follows[13]:

$$\tau_{yd} = \alpha_1 \cdot H^{\beta} \tag{4}$$

$$H = \frac{NI}{2h} \tag{5}$$

where the proportional coefficient α_1 and the exponent β are intrinsic values of the MR fluid, N is the number of turns of the coil, and I is the input control current.

Therefore, the relationship between the brake torque and input current can be achieved by substituting Eq. 4 and Eq. 5 into Eq. 3, yielding

$$T = \frac{4}{3}\pi\alpha_1\left(r_o^{\ 3} - r_i^{\ 3}\right)\left(\frac{NI}{2h}\right)^{\beta} + \frac{\pi\eta\omega}{h}\left(r_o^{\ 4} - r_i^{\ 4}\right). \tag{6}$$

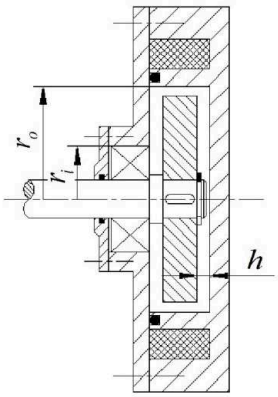

Fig. 6 Schematic of MR brake part

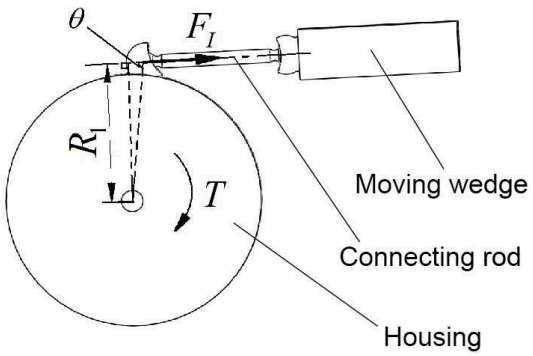

Fig. 7 Schematic of the transform mechanism

Since the amplified component of the input force of wedge mechanism is parallel to the rotating plane of the housing of MR brake part, the calculation of the input force can be simplified with the help of Fig. 7 and it can be expressed in Eq. 7:

$$F_I = \frac{T}{R_1 \sin\theta} \tag{7}$$

where R_1 is the distance between the rotate centers of the MR brake part and the ball joint of the connecting rod, and θ is the angle between the rod and the connecting line of the two above mentioned centers. Here, the tension force of the spring can be neglected during braking since it is quite small compared with the force transformed by the housing.

Combined Eq. 7 with Eq. 2, the brake torque of the proposed MR brake can be expressed as Eq. 8:

$$T_b = \frac{T}{R_1 \sin\theta} \cdot \frac{\mu}{\tan\alpha - \mu} \cdot R_2 \tag{8}$$

where R_2 is the effective radius of the brake disk. In this way, the amplification factor of the brake torque compared with typical single-disk-type MR brakes can be yielded as follows:

$$\gamma = \frac{T_b}{T} = \frac{R_2}{R_1 \sin\theta} \cdot \frac{\mu}{\tan\alpha - \mu} \tag{9}$$

where γ is the amplification factor. Since R_2 is larger than R_1, the self-energizing capability of the proposed MR brakes is higher than that of wedge brakes. Furthermore, different amplification factors γ can be achieved by verifying design parameters such as R_1, R_2, the wedge angle α etc.

Finally, the relationship between the brake torque and the input control current can be obtained by integrating Eq. 6 into Eq. 8, thus yielding

$$T_b = \left\{ \frac{4}{3}\pi\alpha_1 \left(r_o^{\,3} - r_i^{\,3} \right) \left(\frac{NI}{2h} \right)^{\beta} + \frac{\pi\eta\omega}{h} \left(r_o^{\,4} - r_i^{\,4} \right) \right\} \cdot \gamma . \tag{10}$$

To validate results of the above torque analysis in a visible way, numerical calculation should be carried out. Assumption of the parameters is made as follows: $R_2 = 150\,mm$, $R_1 = 60mm$, $\theta = 90°$, $\omega = 100rad/s$. Parameters of the wedge mechanism [14]: $\alpha = 24.2°$, $\mu = 0.35$. Parameters of the MR brake part: $r_o = 40mm$, $r_i = 10mm$, $h = 1mm$, $N = 1200$. Parameters of typical MR fluids [11]: $\alpha_1 = 7.714 \times 10^{-4}\, Pa(m/A)^{1.5}$, $\beta = 1.5$, $\eta = 0.0925\, Pa \cdot s$. The generated brake torque of the proposed MR brakes compared with typical single-disk-type MR brakes, corresponding to different input currents are shown in Fig. 8. The brake torque is significantly amplified, for example, from $2036Nm$ at $I = 2A$ to $17923Nm$ with an amplifying factor $\gamma = 8.8$. Thus its brake torque is large enough for the application as automotive brakes. It is also shown that the brake torque increases with the increasing input currents.

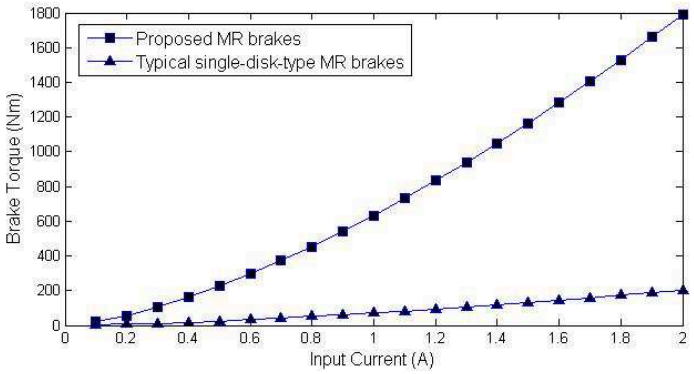

Fig. 8 Comparison of the brake torque under different input currents.

Conclusion

In this paper, an MR based Brake-by-wire system with self-energizing capability was proposed in order to enlarge the brake torque so that it can be adopted as automotive brake system. It combined a typical single-disk-type MR brake with a wedge mechanism. The configuration and operational principle were presented in details. Finally, according to the torque analysis, it was shown that the proposed MR brakes could generate much larger brake torque than conventional MR brakes, thus they can be adopted as automotive Brake-by-wire system.

Keywords: Bridges, Expansion joints, Cleaning machine, Optimization, Cyclone dust removal

Abstract. Bridges are hinges of city road and railway, which play an important function in national economy. The changes of temperature affect the length of the highway bridge beams, so the bridge should be equipped with the expansion joint device. When vehicles pass the bridge, dust flies up and clogs the gap of the bridges. The bridge expansion joints should be cleaned in time. The main task of this project is to study a kind of device used to clean the bridge expansion joints, which including two parts: the cleaning system and vacuum dust removal system. First, we use the sweeping wheels to loose dust, then the air-blower to blow away the dust. The optimization of vacuum dust removal system was discussed in this paper. Especially, the Cyclone dust removal device works well. The machine is of higher productivity, wide application, low energy consumption, simple structure compared with similar equipments.

Introduction

With rapid development of the national economy, the highway is becoming longer, but there exist many questions such as complex terrain , complex structures, and the proportion of bridges is incresing. Bridge plays a significant role in the national infrastructural construction, the maintenance of expansion joints become an urgent problem to be solved for Highway Management.

Bridge Expansion Joints and the Maintenance Methods

Temperature changes will affect the length of the highway bridge beam which can cause some tiny displacements at the end of the bridge beam . Therefore, the bridge expansion joint device must be installed to adapt to this displacement of the beam in road and bridge construction to ensure road safety, as shown in Figure.1. Expansion joint inspection and maintenance is an important part of the bridge safety inspection, it must be inspected timely and conveniently. Because of the accumulation of sand and other debris, as shown in Figure.2, resulting in function loss of expansion joints which will cause the damage of bridge when the temperature rises. According to the above statement, it is very important to clean up the expansion joint[1-2]. But the current bridge expansion joints conservation technology is still relatively inferior, mostly restricted to disassemble or manual cleaning, the cleaning efficiency is low and the operating environment is harsh, there are some security risks. Some researchers invented the device to improve conservation efficiency, these studies exists different advantages and disadvantages [3-5].

Fig. 1 Expansion Joints on the Bridge

Fig. 2 The Gravel Accumulation of the Expansion Joints

The Overall Design of the Cleaning Machine

Based on the Science and Technology Innovation Project of Transportation Department of Shandong, we designed structure of the bridge expansion joints cleaning machine and made the optimization of the main vacuum dust removal system.

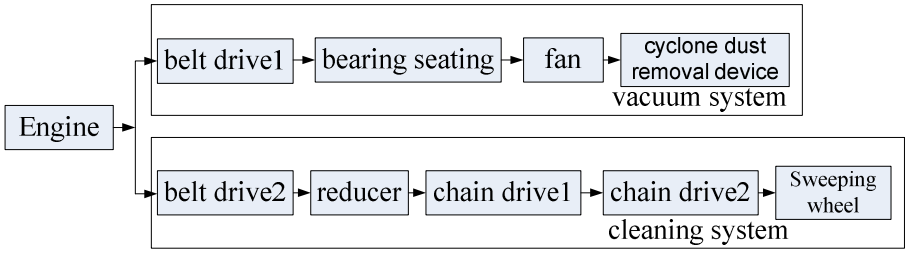

Fig. 3 The Overall Design of the Cleaning Machine

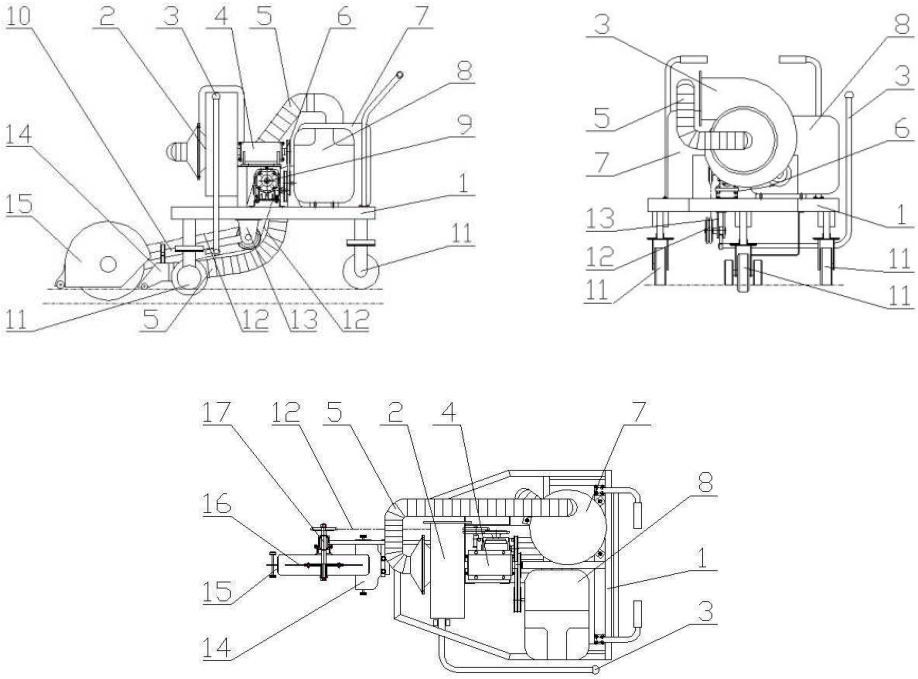
The overall design of the cleaning machine is divided into two systems, as seen in figure.3, cleaning system used to drive the cleaning wheel and the vacuum system to clean up the debris. The debris will become loose when the sweeping wheel rotates and the cyclone dust removal device will remove them in the end.



The power of these two systems was transferred by belt drive assembled from engine. The speed of the sweeping wheel can not be too high, so we chose the worm gear reducer to reduce the speed. We chose the belt of SPZ to make the machine more compact, and the worm gear reducer can provide small volume and big speed reduce range. Two chain drives were used to connect the sweeping wheel. The system was optimized to design the adjust seat to adapt complex working environment. Whole structure of the cleaning machine is shown in figure.4.

The Design and Optimization of Vacuum Cleaning Device

The vacuum attraction system was applied to the cleaning machine to clean up the gravel and debris in the joints, so there is a dust collection box in the front of the blower .The volume of traditional dust collection box is very large and it makes use of area change to generate sudden

pressure changes, so the dust was removed by this theory. But this traditional method is less efficient, then the dust removal device has been optimized in this study.

As shown in Figure.5, the dust box entrance was connected to the cleaning device and the air with gravel and debris is pulled into the box, the air flows along screw path under the function of spiral blade and intermediate cylinder which plays a part of cyclone separator, then the air flows into intermediate cylinder, upper strainers can cleaned the air further. The air without dust runs into the blower through the export.

Fig.4 The Structure of the Cleaning Machine

The blade has an inclination angle (we call it “b”) and there is a gap between the cylinder and the blade (we call it “a”) ,the filtered dust drop into the bottom of the box through the gap. Besides, there was a rotary switch under the cylinder, it closed because of the pressure of the wind flow to prevent the un-filtered dust into the box. But it will open freely to assure the dust drop into the bottom of the box. After optimization, the cleaning machine will be more efficient in similar device and it’s structure is more compact.

Summary

In this project we focus on the study of the general structure of cleaning machine used to clean the expansion joint and emphasized on the design and optimization of vacuum cleaning device with cyclone dust removal system which improved the efficiency of the whole device. The machine has characteristics of high productivity, low energy consumption, simple structure compared with similar domestic equipments.

Key words: suspension system parameters optimization; ride comfort; surrogate model method; radial basis function method.

Abstract. In this article a surrogate model between suspension system parameters of tracked vehicle and comfort evaluation indices has been built up by using radial basis function method and the dynamic simulation of tracked vehicle. Then the optimization of suspension system parameters has been carried out by using surrogate model and adaptive simulated annealing optimization arithmetic. The results show that the research method is feasible.

Introduction

A lot of efforts have been done to improve the ride comfort of wheeled vehicle [1,2]. However, parameter optimization about the ride comfort is so infrequent in the field of tracked vehicle. In this paper an effective parameter optimization design method is discussed which research object is a certain type of light-duty high-speed tracked vehicle. The multibody dynamic model of the tracked vehicle has been founded and the experimental verification has been carried out. Then the surrogate model between suspension system parameters and comfort evaluation indices has been built up by using radial basis function method and dynamic simulation of tracked vehicle. At last, the suspension system parameters have been optimized using the optimization algorithm about adaptive simulated annealing (ASA).

Dynamic Model of Tracked Vehicle and Experimental Verification

The dynamic model of tracked vehicle which has been founded in the environment of Recurdyn software is shown in Fig. 1.

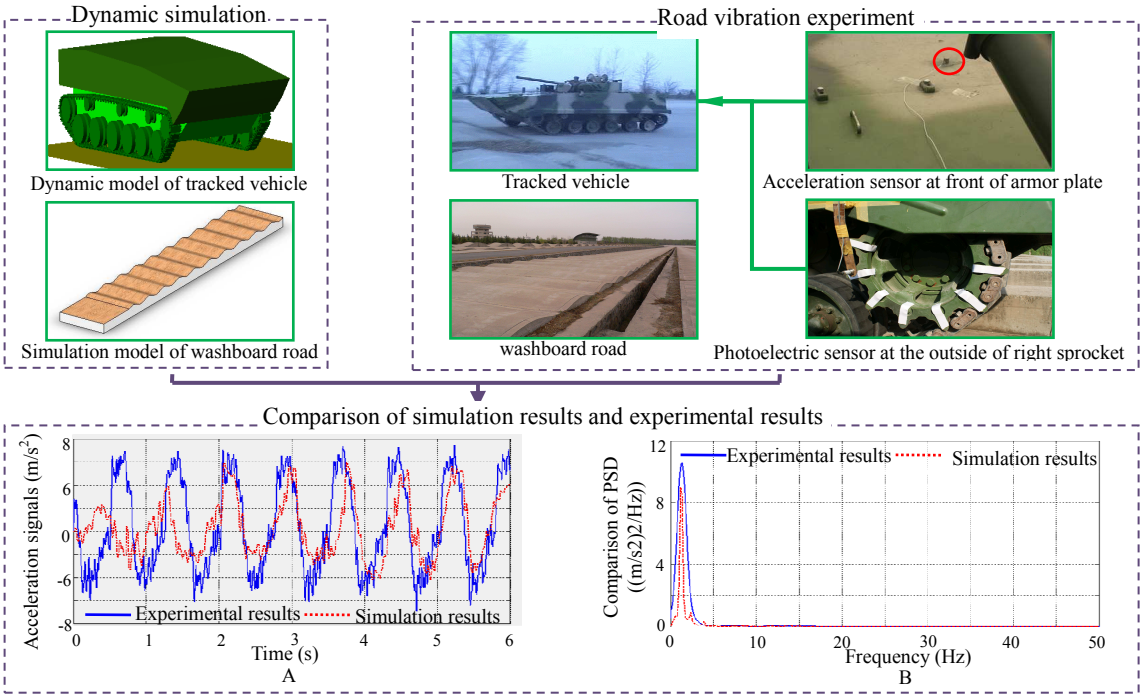

Fig.1 Dynamic Simulation, Road Vibration Experiment and Comparison of Results

A road vibration experiment has been carried out to verify the credibility of the vehicle dynamic simulation model. An acceleration sensor has been installed at front of armor plate in the vehicle to collect the acceleration signals in virtual direction; A photoelectric sensor has been installed at the outside of right sprocket to collect the rotation speed signals, which are shown in Fig. 1. A washboard road which amplitude is 15cm is selected as the experimental road. Comparisons as shown as in Fig. 1 have been made between simulation acceleration signals and actual experimental acceleration signals which are collected and processed from sensor at front of armor plate. It indicates that there is a good consistence between these signals both in time domain (shown in Fig. A) and in frequency domain (shown in Fig. B), that is to say, the dynamic simulation model can meet the need of evaluation of ride comfort.

Basic Theory of Radial Basis Function Surrogate Model Method

Radial basis function (RBF) which is one kind method of Surrogate model Methodology (RMM)[3] has advantages of time saving, simplicity by using least square method to parameter estimation[4]. The basic idea of RBF is the weighted interpolation to primary function of euclidean distance. For N data points where $x_1,\ldots,x_N \in \Omega \subset R^N$, the primary function can be defined as

$$g_j \equiv g(\|x-x_j\|) \in R, \quad j=1,\ldots,N, \tag{1}$$

where $\|x-x_j\|$ is the Euclidean distance space, $g(\|x-x_j\|)$ can be any forms of low-order polynomial. $\|x-x_j\|c$ is selected as RBF where $0.2<c<3$. Consequently, c can be ensured the obtainment of the optimal approximation function results.

Assume that the function values of N data points are $y_1,\ldots,y_N \in R$, then the interpolation function can be determined by RBF as

$$F(x)=\sum_{j=1}^{N}\alpha_j g_j(x)+\alpha_{N+1}, \tag{2}$$

Bringing x_i and y_i which has a number of N groups into Eq. 2, let $\sum_{j=1}^{N}\alpha_j=0$, so N groups of linear equations can be determined as

$$\sum_{j=1}^{N} \alpha_j g_j(x_i) + \alpha_{N+1} = y_i \quad i = 1, \ldots, N, \tag{3}$$

let $p = \begin{bmatrix} 1 \\ \vdots \\ 1 \end{bmatrix} \in R^N$, $G = \begin{bmatrix} g_1(x_1) & \cdots & g_N(x_1) \\ \vdots & \ddots & \vdots \\ g_1(x_N) & \cdots & g_N(x_N) \end{bmatrix} \in R^{N \times N}$, $H = \begin{bmatrix} G & p \\ p^T & 0 \end{bmatrix} \in R^{(N+1)\times(N+1)}$,

$\alpha = (\alpha_1, \ \ldots, \ \alpha_{N+1})^T$ and $y = (y_1, \cdots, y_N, 0)^T \in R^{N+1}$, So Eq. 4 can be transformed into $H\alpha = y$, and

$$\alpha = H^{-1} y, \tag{4}$$

Bringing the value of α from Eq. 4 into Eq. 2, the interpolation functions from $x_1, \ldots, x_N \in \Omega \subset R^N$ to $y_1, \ldots, y_N \in R$ can be obtained.

Suspension System Parameters Optimization of Tracked Vehicle

Design Variable

For the tracked vehicle with torsion bars independent suspensions, what have the biggest effect on the ride comfort are the stiffness of torsion bars and the damping of damper. In this paper variable *K* and *C* are expressed as stiffness coefficient of torsion bars and damping coefficient of torsion spring which belong to the 1st, 2nd, and 6th of road wheel separately at the dynamic model of tracked vehicle. In order to ensure that there is no big change of the hull attitude, the pre-install angle α of road arm is defined as the function of stiffness coefficient of torsion bars *K*

$$\alpha = K_0(\alpha_0 - \alpha_s)/K + \alpha_s, \tag{5}$$

where K_0 is initial value of stiffness coefficient of torsion spring, α_0 is initial value of pre-install angle of road arm and α_s is statical inclination angle of road arm.

Considering the limitations of combining engineering practice and safety factors, α is assumed not more than 80°, therefore, the change range of design variables are shown in Table 1.

TAB1 CHANGE RANGE OF DESIGN VARIABLES

design variables	lower limit	initial value	upper limit
K	5340（-45.2%）	9743	14147（+45.2%）
C	0（-100%）	2187	4375（+100%）

Constraint Conditions and Objective Function

When there is an impact between road arm and stopper during the riding of vehicle, the ride comfort will be badly damaged. In order to minimize the probability of impact, the dynamical inclination angle of road arm should meet the condition

$$[\alpha_d] \geq 3\sigma_f, \tag{6}$$

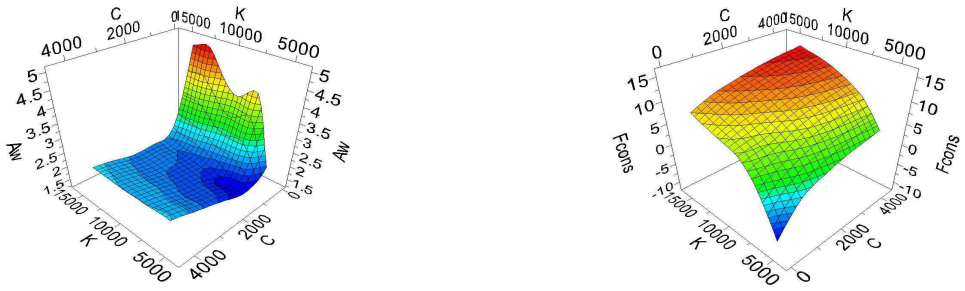
where, σ_f is the RMS of dynamical inclination angle at the 1st right road arm.

Assuming that $\alpha_{\max}$ is maximum allowing twisting angle of torsion bar and $[a_d] = \alpha_{\max} - \alpha + \alpha_s$, as a result, the constraint condition of optimization design can be determined as

$$s.t. \quad F_{cons} = (\alpha_{\max} - \alpha + \alpha_s)/3 - \sigma_f \geq 0, \tag{7}$$

According to Ref. [5], the total weighted acceleration RMS A_w at the position of driver's seat is selected as the ride comfort evaluation index. So the objective function which is the minimum total weighted acceleration RMS can be shown as,

$$min \quad F_{obj} = A_w, \tag{8}$$



Optimization Results.k

In order to make the optimization results meet the driving requirement of vehicle, a rough road model with rank of F and the speed of 10km/h, 20km/h, 30km/h and 40km/h are selected as the driving condition of dynamic model, then, 36 sample points are get according to the dynamic

simulation and the experimental design of two-factors and six levels. The surrogate models between K, C and evaluations indices A_w , F_{cons} have been built up based on RBF using these sample points. The surrogate models under the speed of 40 km/h are shown in Fig. 2.

TAB.2 THE RESULT OF ERROR ANALYSIS OF SURROGATE MODEL

velocity [km/h]	10	20	30	40
A_w	0.032	0.034	0.023	0.038
F_{cons}	0.003	0.006	0.005	0.004

A surrogate Model between Design Parameters and Aw B surrogate Model between Design Parameters and Fcons

Fig.2 The Surrogate Model when Vehicle Velocity is 40km/h

An error analysis has been given in Table 2 for checking the fitting accuracy of surrogate model. It is proved that the fitting accuracy is acceptable. That is to say, the surrogate models can meet the need of suspension system parameters optimization. Then, the optimal combinations of suspension parameters under four kinds of velocity which are shown in Table 3 has been obtained after about 800 times of iterations using Adaptive simulated annealing (ASA)[6] and surrogate model.

TAB.3 THE RESULT OF PARAMETERS DESIGN OPTIMIZATION

velocity [km/h]	K	C	A_w	F_{cons}
10	7537	1260	0.697	4.423
20	6388	1190	1.058	2.004
30	6078	1232	1.254	2.000
40	6908	1243	1.363	3.276

Comparison between Surrogate Model Optimal Result and Virtual Evaluation Result

To verify the optimal results of suspension system parameters based on surrogate model, an virtual evaluation about ride comfort of tracked vehicle has been made using the optimal combination parameters. The simulation environment of virtual evaluation is as same as the driving condition of building up the surrogate model. The comparison about ride comfort between virtual evaluation result and optimized result based on surrogate model is shown in Table 4 and Fig. 3.

TAB4 COMPARED RESULT BETWEEN VIRTUAL EVALUATION RESULT AND OPTIMIZED RESULT BASED ON SURROGATE MODEL

velocity [km/h]	A_{w1}	F_{cons1}	A_{w2}	F_{cons2}	A_{w0}	F_{cons0}
10	0.696	4.422	0.739	5.346	0.798	10.965
20	1.057	2.004	1.072	2.494	1.167	10.302
30	1.254	2.000	1.301	2.219	1.546	10.239
40	1.363	7.945	1.501	3.386	1.775	9.989

Remarks: Among the evaluation indices of ride comfort in this table, subscript 0 denotes non-optimal result, subscript 1 denotes optimal result based on surrogate model, subscript 2 denotes optimal result based on virtual evaluation result

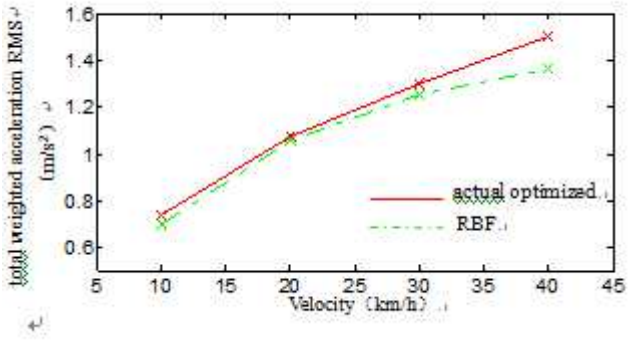


Fig.3 Compared Result Between Virtual Evaluation Result and Optimized Result Based on Surrogate Model

As fitting errors between surrogate model and actual function, there is a little difference between optimal result based on surrogate model and optimal result based on virtual evaluation using the optimal parameters. The maximum difference is 9.2% when the velocity is 40km/h, while the minimum difference is only 1.4% when the velocity is 20 km/h. As a result, surrogate model which are built up based on RBF can meet the need of suspension system parameters optimization of tracked vehicle.

It is shown in Table 4 that the ride comfort of vehicle has been improved after optimization design, especially when the vehicle is driving under a high velocity.

Conclusions

In this paper a dynamic model of high-speed tracked vehicle has been founded which credibility are verified by carrying out a road vibration experiment. The surrogate model between suspension system parameters of tracked vehicle and evaluation indices of ride comfort has been built up based on radial basis function method and dynamic simulation of vehicle. The ride comfort of vehicle has been improved after optimization design by using ASA and surrogate model. The results show that this research method is feasible and can be the basis of vehicle performance improvement.

Keywords:superheater; simulation;heat transfer;flow.

Abstract: According to the basic mechanism of the supercharged boiler superheater, a superheater simulation model was established. The simulation about a whole superheater system including the flue gas,steam and tube wall was conducted according to the simulation model.Therefore, the internal working laws of superheater system are revealed by the simulation results.

Introduction

Superheater is one of the most important parts of a steam power plant. It not only recover energy from the high temperature and highly corrosive flue, but also improving the quality of steam to provide protection for the safe operation of the turbine. Superheater wall subjected to high temperature flue gas erosion and superheated steam flowing inside the superheater, so the working conditions of superheater is very poor. With the improving of modern steam power system parameters, the temperature of superheater tube wall is close to the temperature of the wall material allows. Due to the unreasonable structural design, deviate from the design point run, variable load operation frequently and other reasons, the localized over-temperature and tube rupture frequently occur in the actual operation of the superheater. It is affects the safety and efficient operation of the power plant seriously. Therefore, the simulation study of the structure design and operation of the superheater have important practical significance to forecast the problems that may arise during the superheater design and operation.

Current studies of the superheater are focuses on the numerical simulation of internal field and strength analysis. Purbolaksono J[1]and Pronobis M[2]applied finite element software to calculate the heat flux distribution under different conditions. Madejski Pawel[3]and Taler D[4]had numerical calculation on the superheater tube wall temperature distribution and analyzed the stress in order to study the causes of over-temperature. Wojnar W[5]proposed distribution model of superheater and analyzed the impact of the changes in the specific heat of the steam on temperature distribution. Based on the working mechanism of the superheater, we established the mathematical model of superheater infinitesimal segment in order to learn supercharged boiler superheater heat transfer and flow characteristics in this paper. The heat transfer coefficient of the inner and outer walls has been amended accordingly to consider the impact of the internal wall dirt and the outer wall grime on the temperature distribution. At last, we programmed and debugged the superheater mathematical model simulation procedures using C language in Visual C + +6.0 platforms and simulated the internal transfer and flow field of supercharged boiler superheater.

Mathematical model

The supercharged boiler superheater work process is flue across the metal wall. Superheated steam as the working fluid flow within the pipe and flue gas flow outside. The heat transfer process is a typical cross-flow heat exchanger. The three-dimensional geometric model of experimental platform supercharged boiler superheater as shown in Figure 1.

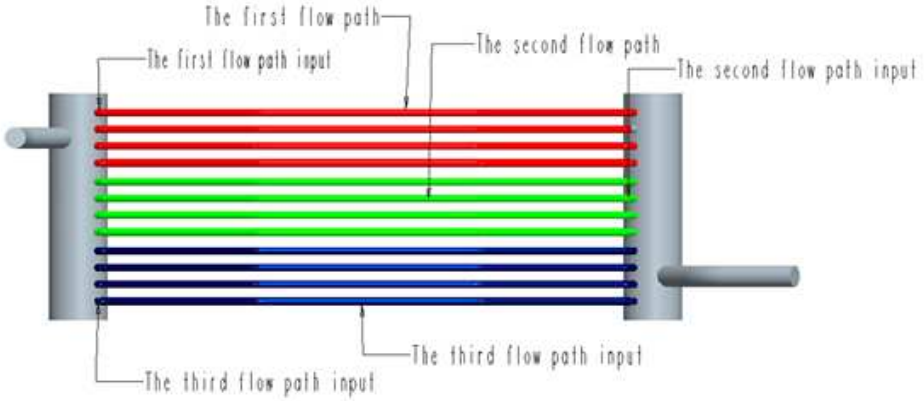

Fig1 Three-dimensional geometric model of superheater

Superheater tubes are arranged in the back of the convection evaporation bundle and occupy the entire width of the flue. It's a counter-flow and cross-flow heat exchanger. The superheater is divided into three passes, consists of 12 rows and each row contain 3 tubes. The specific spatial arrangement as follows:

The first flow path: located in the tail four rows of superheater, steam flows from top to bottom in the inner tube.

The second flow path: located in the middle four rows of superheater, steam flows from bottom to top in the inner tube.

The third flow path: located in the front four rows of superheater, steam flows from top to bottom in the inner tube.

The flue gas laterally scour tube wall of the third, second and first flow path successively and the steam vertical scour tube wall of the first, second and third flow path successively. Specific structural parameters as shown in Table 1.

TAB1 THE MAIN STRUCTURAL PARAMETERS OF THE SUPERHEATER

Number	Name	Unit	Value
1	The number of the first flow pass tubes	—	12
2	The number of the second flow pass tubes	—	12
3	The number of the third flow pass tubes	—	12
4	Outside diameter/d_o	mm	20
5	Inside diameter/d_i	mm	14
6	Wall thickness / δ	mm	3
7	Lateral distance /s_1	mm	32
8	Longitudinal distance /s_2	mm	45
9	Tube length / L	mm	1535

The assumptions of the working fluid

(1) Gas side: flue gas has the uniform physical parameters in the same section along its flow direction, flue gas temperature only changes along the direction of flow.

(2) Steam side and the tube wall: the flow of steam near the plug flow and there is no axial mixing, steam has the uniform physical parameters in the same section along its flow direction, the temperature of the wall only changes in the axial direction.

Mathematical equations

The superheater is discrete into a number of infinitesimal segments along the flue gas flow direction, the axis of Tube bundle direction and the width of flue area direction. Supercharged boiler superheater mainly absorb heat from the flue gas rely on convection heat transfer and the radiant heat exchanger was very small. Therefore, we do not consider the effects of radiation[6]. For the purposes of infinitesimal superheater, it is still a cross-flow heat exchanger. Therefore, the ε -NTU method was used to analysis and calculation. For superheater infinitesimal segment, there are:

$$\varepsilon = \frac{1-\exp\{-Rc[1-\exp(-NTU)]\}}{Rc} \tag{1}$$

$$NTU = [(\frac{1}{K_q \pi d_i dx} + \frac{1}{K_y \pi d_o dx} + k_{wg} + k_{hg}) m_y C_{py}]^{-1} \tag{2}$$

$$Rc = \frac{m_y C_{py}}{m_q C_{pq}} \tag{3}$$

And according to the heat balance equation and the heat transfer equation:

$$\varepsilon m_y C_{py}(T_{yin} - T_{qin}) = m_q C_{pq}(T_q - T_{qin}) = m_y C_{py}(T_{yin} - T_y) \tag{4}$$

$$K_y \pi d_o dx(T_y - T_w) = K_q \pi d_i dx(T_w - T_q) \tag{5}$$

Where:

y, q, w are for flue gas, steam and wall,respectively;

T——temperature, ℃;

di ,do——the inner and outer diameter of the tubes, m;

Cp——specific heat capacity at constant pressure, J/(kg·K);

K——heat transfer coefficient, W/(㎡·K);

k_{wg}——fouling resistance, K/W;

k_{hg}——ash resistance, K/W;

m——mass flow, kg/s.

The temperature of outlet flue gas,steam and tube wall can be obtained by solve the above equations.

The steady-state simulation

The simulation program was written in C language and running on Visual C++6.0 platform.

The calculation of thermo-physical properties

The working fluids of the superheater have larger temperature difference between each pass during the pressurized boiler running, which leads to the physical properties of the working fluid is very different.To make the established model reflect the characteristics of superheater operating more accurately, we call the flue gas properties program which have been compiled[7]and 《IAPWS-IF97/IFC67 water and steam properties calculation package》.So we can always call the working fluid thermal parameters depending on the temperature and pressure.

The initial boundary conditions

The input conditions of the program including:steam flow rate, steam inlet temperature and pressure, fuel consumption, flue gas inlet pressure and temperature.Their values are given based on supercharged boiler experiment platform test data ,as shown in Table 2.

TABE2 SUPERCHARGED BOILER EXPERIMENT PLATFORM TEST DATA

Fuel consumption, kg/h		64.0
Steam	Inlet temperature, ℃	174.1
	Inlet pressure, MPa	0.7012
	Flow rate, t/h	0.6627
Flue gas	Inlet temperature, ℃	491.2
	Pressure, kPa	61.3

The results and analysis of simulation

Fig2 shows the steam temperature change along the flow direction.Along the steam flow, steam continue to receive heat from the tube wall and the temperature gradually increased.It is clear that steam temperature is substantially linear with the distance between location and the entrance. This means that the steam endothermic along the axis of the tube bundle is uniform.

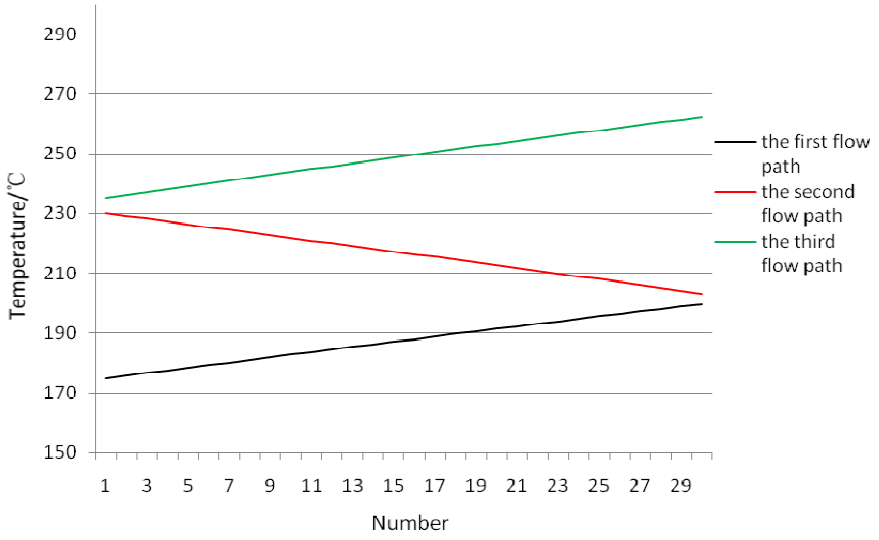

Fig2 Steam temperature change along the flow direction

Fig3 and Fig4 shows steam and flue gas convective heat transfer coefficient values at different tube row, respectively. From the figure we learn that steam heat transfer coefficient gradually decreases after steam flowing through the first,second and third pass.The heat transfer coefficient between steam and the inner tube wall is related to the physical properties and flow rate of the fluid. The steam temperature gradually increasing along the direction of steam flow,this leads to vapor density and Prandtl number decrease while kinematic viscosity, dynamic viscosity and thermal conductivity increase. Although the temperature of steam in the first flow path is lower, the density is large and kinematic viscosity is small, both of them have the combined effects on the Reynolds number. As the vapor density is more sensitive to temperature changes,therefore, the Reynolds number of the first pass is greater than the other passes. Prandtl number decreases with increasing temperature, and less sensitive to temperature changs. These factors lead to a greater heat transfer coefficient in the first flow path. Flue gas heat transfer coefficient decreases with the number of rows increases, which is mainly caused by different degrees of disturbance flue gas. Since the

superheater is a countercurrent and cross flow heat exchanger, so the smaller the number of rows, the farther away from the flue gas inlet, the corresponding disturbance is more intense and flue gas heat transfer coefficient is greater. The 12th row pipe located at the entrance of the flue gas, so the heat transfer coefficient is minimum.

Fig3 Steam heat transfer coefficient

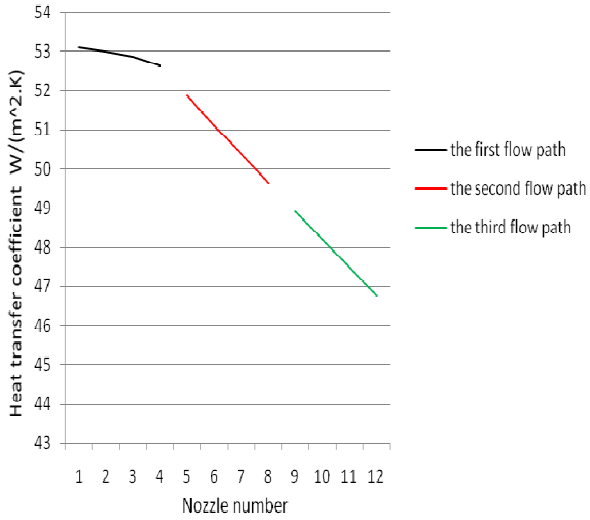

Fig4 Flue gas heat transfer coefficient

Fig 5 shows the heat exchange at different flow path.We can see that heat transfer increased along the flow direction of the flue gas.The factors affected heat transfer in superheater mainly are the total thermal resistance and temperature difference between steam and flue gas.From fig 3 and fig 4 we can see that the first flow path have the minimum total thermal resistance and the third pass is the largest. And the temperature difference is just the opposite. So the heat exchange of each pass is basically the same.

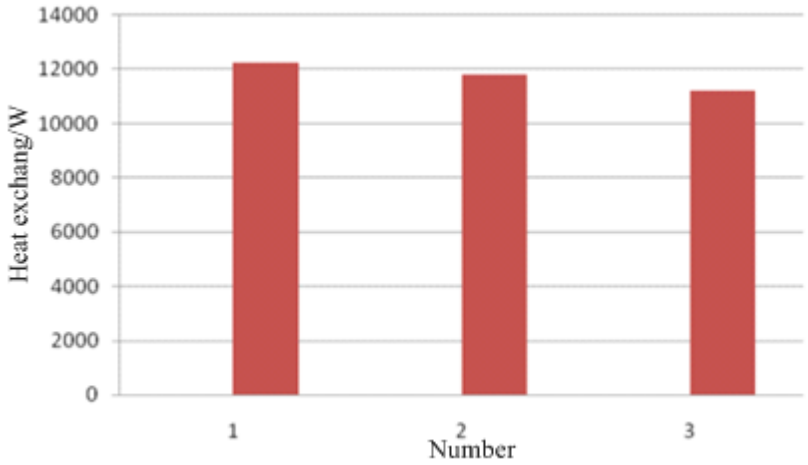

Fig 5 Heat exchange

Conclusion

In this paper, supercharged boiler superheater experimental platform as the research object and a superheater simulation model was established based on the supercharged boiler superheater basic working principle.According to the calculation results it can draw the following conclusions:

(1)The steam temperature changes uniformity along the flow direction and the heat absorption along the axis of the tube bundle is uniform.

(2)The maximum heat transfer coefficient in the first flow path, the third pass has the smallest heat transfer coefficient and the heat exchange of each pass is basically the same.

Keywords: Hull line, Non-Ballast ship, Rise angle, Total resistance, Effective power

Abstract: As a new concept in ship design to be alternative of ballast water system, to emerge that remedy the introduction of invasive marine species and the disadvantages of ballast water treatment systems. The Non-Ballast ship has been studied abroad, but it is rarely mentioned in China. In this paper, the hydrodynamic influences due to hull line variation of this kind of ships were studied, using the method of invariant cross-section area curve under the design draft to change the rise angle at bottom. Then by using numerical calculation, get the resistance and effective power at each angle.

Introduction

The Non-Ballast ship concept was invented and initially investigated at Shipbuilding Research Centre of Japan (SRC) as a way to overcome the introduction of invasive marine species and the disadvantages of ballast water treatment systems.

The paper studies the hydrodynamic effect by changing the rise angle at ship's bottom with a wider breadth, while the major factors such as mid-section area, length, draught, etc. were kept unchanged. In the present research, the hydrodynamic aspects of Non-Ballast concept were further investigated numerically using Maxsurf software to construct the 3D modeling and Hullspeed software to calculate and analyses the resistance performance.

Background

Ships are designed to operate safely while carrying a full load. Ballast water is used to account for situations when vessel has only a partial load or no load at all. The functions of ballast are to maintain a necessary draught to ensure efficient propeller and rudder operation, safe navigation and to avoid bow slamming especially in heavy seas. Ballast water is also used to balance the ship as fuel is used up during a long voyage, or during loading and unloading operations.

The transportation and introduction of invasive marine species into new environments through ships' ballast water, attached to ships' hulls and via other vectors has been identified as one of the four greatest threats to the world's oceans as it cause damage to the environment and impacts on human health, social and economic[1]. Research had targeted technologies that treat ballast water to remove or destroy the living organisms being carried including ballast water exchange, filtration, heat, ultra-violet light, ozone, de-oxygenation, electro ionization and chemical biocides, among others.

However all current treatments techniques would require high cost for installation of sensitive equipment and retrofit on a ship, extra cost of operation, maintenance and training of the ship crew to operate, plus the cost of managing tank sediments. These techniques also require more power which will result in more combustion of fuel and consequently bring more emission gasses and air pollution. In Addition of single treatment method would not provide an effective solution.

Ballast water exchange at sea subject to several serious limitations, including inapplicability on short voyages or when the voyage is mainly in coastal waters, ship safety and stability limitations in rough seas, and highly variable biological effectiveness.

A new concept was invented to be alternative to ballast water system. The concept is based on a V-shaped hull which stems from new thinking about optimal hull shape and buoyancy distribution.

The V-hull alters the vertical distribution of hull buoyancy, causing a deeper draught in the light (unloaded) condition than that of conventional hull as shown in figure (Fig.1). By widening the beam by ~30%, the ship's displacement can be kept at the same full load draught as that of an equivalent deadweight of conventional hull, while hull length is minimally altered.

The V-shape cross-section maintains sufficient unloaded draught and stability and avoid bow slamming and propeller racing without needing any ballast water (BW) for the majority of sea conditions. It also likely provides the potential for better vessel control, reduce hull resistance and improve propulsion efficiency for most speeds and sea conditions.

Overall, the investigation of the Non-Ballast (NoBS) Ship Concept has shown that it provides a viable alternative to the addition of costly ballast water treatment systems in order to meet the evolving performance requirements for ballast water treatment. The concept essentially eliminates the transport of foreign ballast water. This should be more effective than current treatment methods in reducing the potential for the further introduction of nonindigenous aquatic species[2-4]

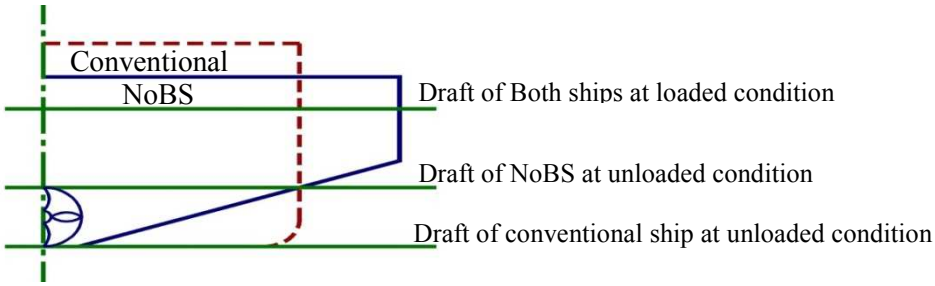

Fig.1Deeper draught of V-hull in its unloaded condition than that of conventional hull

Analysis and Determination of Main Dimensions

In this paper, a 59000 DWT oil tankers selected as the mother ship, which was designed to be V-Hull Non-Ballast ship with principal dimensions shown at table (Table 1).[5] Figure (Fig.2) shown the Maxsurf Pro model for the V-Hull Non-Ballast ship.

TABLE 1 THE V-HULL NON-BALLAST SHIP' MAIN PRINCIPAL DIMENSIONS

Total length L_{OA}	200[m]	Design draft T	12.5[m]
Length between perpendiculars L_{BP}	196[m]	Depth D	19.5[m]
Maximum beam B	32.2[m]	Rise angle at the bottom θ	25°

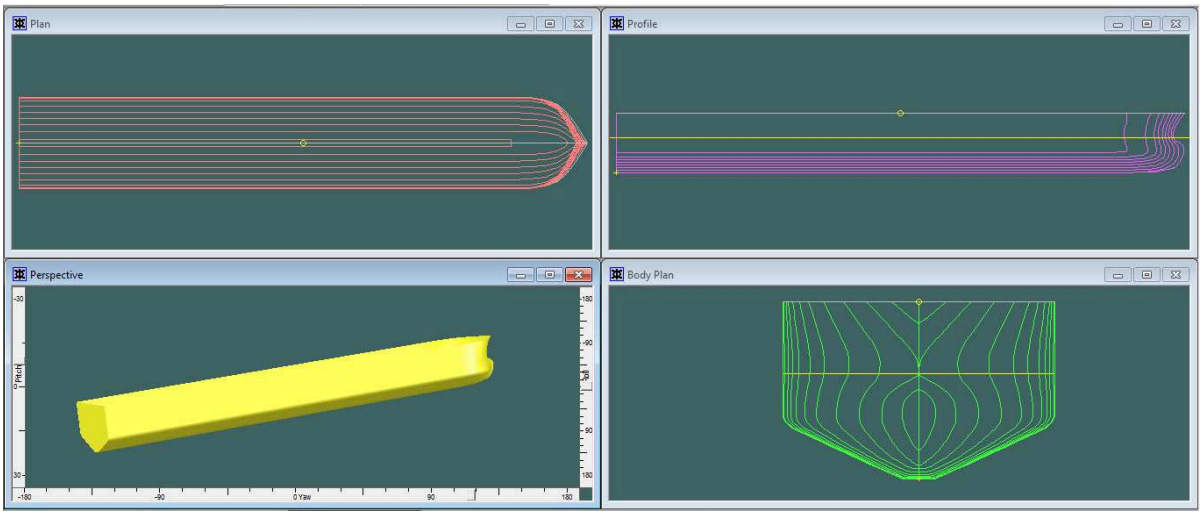

Fig.2 The V- hull Non-Ballast ship Maxsurf Pro model

The rice angle at the bottom θ is altered with the change in beam, while the major factors unchanged according to equation (Eq.1) which base on invariant cross-section area curve under the design draft as shown in figure (Fig.3), The increased area B is equal to the reduced area A.[6]

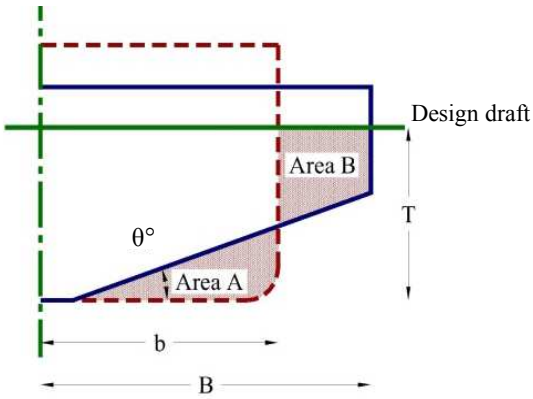

Fig.3 The invariant cross-section area

$$n = \frac{-b(b\tan\theta - T) \pm \sqrt{[2b(b\tan\theta - T)]^2 - 4b^2\tan\theta \times b^2\tan\theta}}{2b^2\tan\theta} \quad (1)$$

Where n is the single coefficient range 0< n <1, b is the half breadth of conventional ship, B= (n+1) b is the half breadth of design ship, and θ is the rise angle. From equation(Eq.1) we can get the half breadth of design ship for changed θ between 10° and 25° as shown in table (Table 2) and figure (Fig 4) with constant draft 12.5 [m]

Table 2 The half breadth of design ship with different θ

θ	T[m]	B[m]	Area A[m^2]	Area B[m^2]
10°	12.5	13.3	9.520277	9.520277
15°	12.5	13.9	14.46716	14.46716
20°	12.5	14.8	19.65156	19.65156
25°	12.5	16.1	25.17696	25.17696

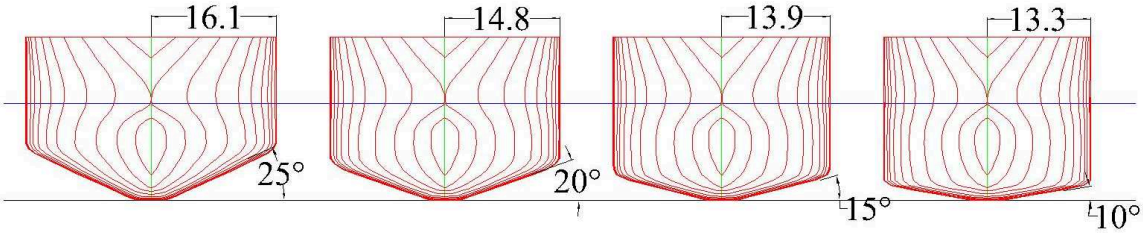

Fig.4 The Maxsurf models

Numerical Investigation

The commercial software Maxsurf is a powerful three-dimensional surface modeling system for use in the field of marine design. Allowing any number of surfaces to be modeled in any given design, offer scope for the creation of a wide range of hull forms. Combined with the built-in hydrostatic calculations, there are a couple of tools to experiment with shapes and explore design parameters. And Hullspeed software provides a means of predicting the resistance of a ship hull. Maxsurf designs may be read in and automatically measured to obtain the required parameters.

In this paper selected the Slender body method from the Hull speed resistance prediction methods, because the models' main principal dimensions achieved the certain limits of hull

dimension, which the resistance prediction algorithms are useful within. The Slender body method calculate the total resistance as equation (Eq.2) and power as equation (Eq.3) [7]

$$R_T = R_W + R_V + R_{Cor} + R_{App} + R_{Air} \quad (2)$$

Where R_T is the total resistance, R_W is wave making resistance; R_V is viscous resistance and equal $(1+k)R_F$ fraction resistance uses the ITTC'57 ship-model correlation line, R_{Cor} is Correlation allowance resistance; R_{App} is Appendage resistance and R_{Air} is wind resistance.

$$P = \frac{R_T V}{\eta} \quad (3)$$

Where P is the power, V is the velocity of ship and η is the efficiency, which is selected to be 75%.

The figure (Fig 5) and figure (Fig 6) shows the result for numerical investigation of total resistance R_T and effective power P respectively, for variation rice angle at bottom θ of model, in range of velocity V from 0 to 17 [kts].

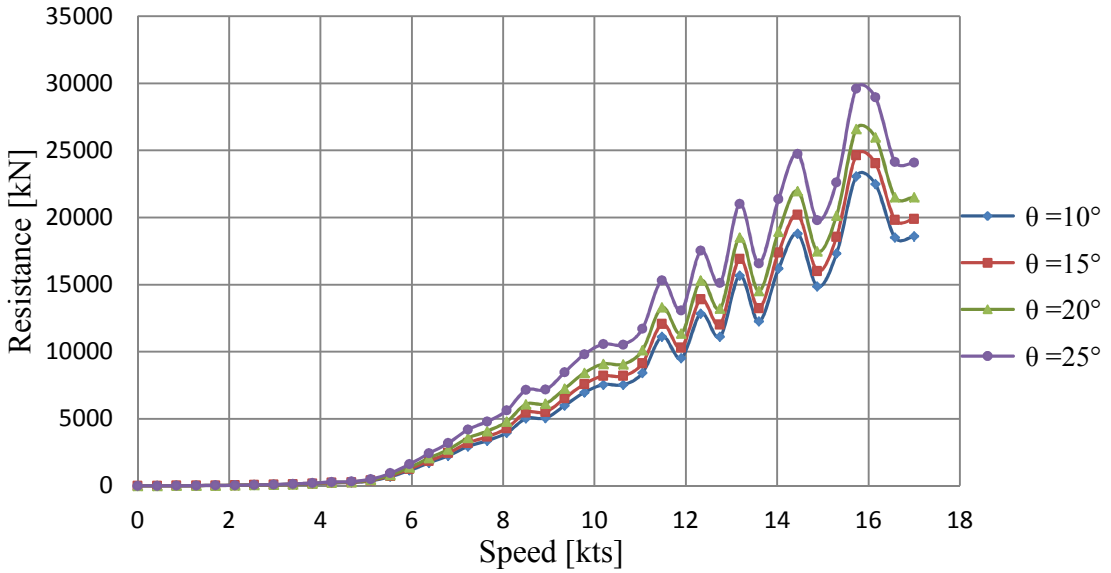

Fig.5 The total resistance

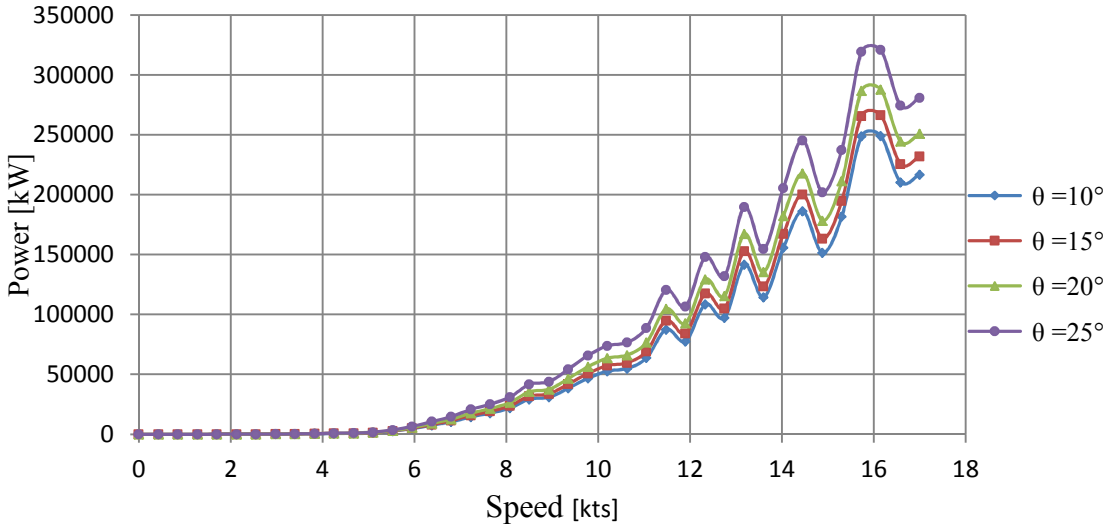

Fig.6 The effective power

Conclusion

From the previous study, the following facts can be deduced. The total resistance will increase with the augment of rise angle at the bottom. Especially under high speed condition, the increate even reach by 22%between the lowest and highest rise angle, due to the broaden breadth, which consequently make the half angle of entrance increase, further affect the wave resistance of ship.

The increase of resistance is not so noticeable at low speed, because the convergence of wet area surface, which not increase than 1.6% between the lowest and highest rice angle. So the frication resistance the main domain resistance at low speed will be approximately the same.

The effective power will increase accordingly as increased total resistance. As a result the fuel oil consumption and the cost of voyage will rise consequently.

The Non-ballast ships as a new concept, from the design to the application there is obviously still a long way to go. But no doubt it is to solve issues of ship ballast water, worth investing more energy to exploration and research.

Keywords: Wave glider; Wigley hull; Resistance; Computational Fluid Dynamics (CFD).

Abstract: The *wave glider* is a surface vehicle with an attached sub-surface wing system which propels the surface component forward, negating the need for a motor. *Wave glider* could be used for intelligence, surveillance, passive monitoring of marine life, monitoring exclusive economic zones for fishing and other economic resources that are important and useful to coastal countries. Monitoring of coastal waters normally requires large amounts of expensive surveillance. They can be used to find and research resources and fisheries at a fraction of the cost of other methods. Since the *wave glider* can either be programmed for a journey or to keep station, it is looked at as an alternative for expensive moored buoys. In this paper we present a method focused on the mesh generation to predict calm water resistance for the floating part of the *wave glider* (the hull). In this study a *wigley hull* form (4m) used as the floating hull has been investigated in order to predict the fluid flow of the ship using *computational fluid dynamics (CFD)*. Calculations for total resistance are carried out for Froude numbers in the range of 0.10 to 0.40. Commercial *CFD* software fluent is used to investigate the fluid flow of *wigley hull*. Three different mesh sizes are used in this study to calculate the mesh effects. The results obtained from *CFD* calculations for total resistance are compared with the experimental results for accuracy of the solution parameters. The comparison shows a good agreement between experimental and *CFD* results. The method is evaluated by comparing the numerical predictions for *wigley hull* form (2m) with *wigley hull* form (4m) using the same mesh sizes under the same conditions in an attempt to design the floating hull of *wave glider* . The results obtained from *CFD* calculations are compared for accuracy of the solution parameters and the method is useful and acceptable.

Introduction

The *wave glider* is a surface vehicle with an attached sub-surface wing system. The wing system is comprised of six individual wings that adjust to the current, speed, and direction of passing waves as shown in figure (1). This system propels the surface component forward, negating the need for a motor. The *wave glider* can be programmed for travel or to keep station at a certain location which is hopeful in the need for replacement of buoys with expensive mooring systems. The *wave glider* has instruments on the surface component that can be customized for ADCP and CTD measurements, passive monitoring of marine life and other commercial applications. The instruments are powered by solar panels on the surface component, making the *wave glider* a self-sustaining vehicle. The vehicle transmits data to land in real-time sequence, allowing for accurate and easy monitoring of the vehicle's trip and the data collected [1].

In current practice, early stage design studies often use empirical data to estimate the total resistance because more sophisticated numerical methods or physical experiments are too expensive or time consuming for preliminary decision making. Unfortunately, empirical data may be misleading when used for new and exotic hull form types that differ significantly from the conventional hulls from which the experiential data has been collected. The objective of this paper is to bring accurate numerical prediction of ship resistance closer to early stage design using a method that relies minimally on empiricism and is flexible and general for application to new and high-performance hull form types.

The *CFD* technology is always developing, especially in terms of new solution techniques, and these developments are often given in terms suitably applicable to the ship building industry. In recent years, the development of advanced computing technology and numerical tools have made the use of *CFD* techniques much more practical with regards to ship resistance calculations [2].

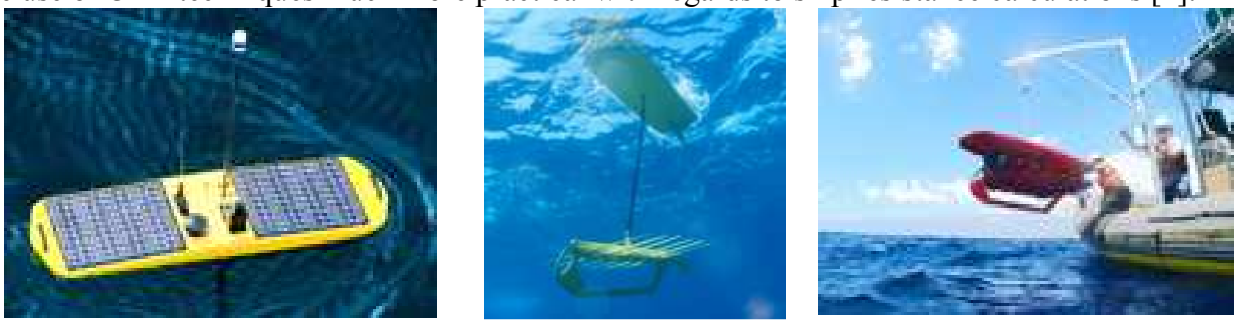

Fig. 1 Wave glider

CFD applications related to ships often concern hydrodynamics problems, which involve the task of computing pressure and velocity components and then further calculating the forces and moments acting on the ship. According to the lake of design information and data for the *wave glider*, the main aim of the study is to investigate the *CFD* capability in solving fluid flow around the *wigley hull* form (2m) compared with *wigley hull* form (4m) using the same mesh sizes under the same conditions by using commercial general-purpose software fluent in an attempt to design the floating hull of *wave glider* [3].

Methodology

Wigley hull model (L=4m) is mathematically defined, simple and has a long history in being used for validation. Although *wigley parabolic hull* is not employed to design actual ships, it is a good test case because of its simple geometrical form and the large amount of experimental and computational data available. These experimental results are compared to *CFD* calculated results to ensure proficiency in *CFD* theory and tools [4].

Mathematical Model used in CFD Calculations

To solve the governing equations for fluid flow, the fluid domain is subdivided into a finite number of cells and these equations are changed into algebraic form via discretion process. Finite volume method is used for the discretion. The coupling between the pressure and velocity fields was achieved using *simple* (semi-implicit methods for pressure- linked equation) algorithm.

The *shear-stress transport* (SST) k − turbulence model is adopted to calculate eddy viscosity in our study; this model is believed to be one of the best choices to simulate turbulence flow around ship hull.

Governing Equations

In this paper, three-dimensional steady, incompressible, two-phase (air and water), and viscous turbulent flow is used. For incompressible flow, well known, continuity and *Navier – Stokes* equation are given by:

$$\frac{\partial ui}{\partial xi} = 0 \tag{1}$$

$$\frac{\partial}{\partial xj}(\rho u_i u_j) = \frac{\partial}{\partial xj}\left[\mu\left(\frac{\partial ui}{\partial xj} + \frac{\partial uj}{\partial xi}\right) - \left(\frac{2}{3}\mu\frac{\partial uj}{\partial xi}\right)\right] - \frac{\partial p}{\partial xi} + \frac{\partial}{\partial xj}(-\rho u_i' u_j') \tag{2}$$

Where u_i and u_j are time-averaged velocity components (i, j=1,2,3), ρ is fluid density, p is pressure and μ is dynamic viscosity. In this equation, additional terms appear that represent the effects of turbulence and $-\rho u_i' u_j'$ is called *Reynolds stress* which must be modeled in order to close the equations. A turbulence model is required here in order to close the system of *RANS* equations.

SST k-ω model is developed by Menter [5]. Transport Equations for the SST k-ω Model

$$\frac{\partial}{\partial t}(\rho k) + \frac{\partial}{\partial xi}(\rho k \mathrm{ui}) = \frac{\partial}{\partial xj}\left(\Gamma k \frac{\partial k}{\partial xj}\right) + G\tilde{}k + Yk + Sk \quad (3)$$

$$\frac{\partial}{\partial t}(\rho \omega) + \frac{\partial}{\partial xi}(\rho \omega \mathrm{ui}) = \frac{\partial}{\partial xj}\left(\Gamma \omega \frac{\partial \omega}{\partial xj}\right) + G\tilde{}\omega - Y\omega + D\omega + Sw \quad (4)$$

In these equations, $G\tilde{}_k$ represents the generation of turbulence kinetic energy due to mean velocity gradients, G_ω represents the generation of ω, Γ_k and Γ_ω represent the effective diffusivity of k and ω respectively. S_k and S_ω are user-defined source terms. Y_k and Y_ω represent the dissipation of k and ω due to turbulence. D_ω represents the cross-diffusion term.

Computational Domain and Grid Generation

The ship model used for this study is *wigley hull* with block coefficient (C_B) of 0.222. *Wigley hull* model is a standard for ship-hydrodynamics research and it is one of the hull forms used by ITTC research program. The characteristics of hull model and the longitudinal profile of the 3D model used for *CFD* calculations are given in table (1).

TABLE 1. CHARACTERISTICS OF HULL MODEL

Description	Units	Dimensions	Description	Units	Dimensions
Length	L (m)	4.00	Wetted Surface Area	S (m2)	3.227908
Beam	b (m)	0.80	Water Density	(Kg.sec2/m4)	101.930
Draft	d (m)	0.25	Kinematic Viscosity	(m2 /sec)	1.2845*10-6
Temperature	c○	10.6	Volume of displacement	∇ (m3)	0.1777

A complete *CFD* solution requires three major steps: preprocessing, analysis of the problem using a solver and post processing the results. Preprocessing of the solution involves geometry creation of the model, and an appropriate mesh generation. In this study, preprocessing of the solution is carried out in *gambit* software. The geometry of the hull is obtained by the use of offset table as shown in figure (2). This offset data is imported into *gambit* in the form of vertices and then 3-D model is generated. The major dimensions of the *wigley hull* are given in table (1). For flow calculations, half of the *wigley hull* is modeled due to the symmetry of hull. The domain volume is taken to be of cylinder shape. The overall size of the cylinder is 5Lx1.5Lx L. The Cartesian coordinate system is setup with x-axis pointing towards the bow, y-axis upwards and z-axis to portside. The length in front of the hull (inlet boundary) is taken as 1.0L (main hull), the length behind the hull (outlet boundary) is taken as 3.0L (main hull). The top, bottom and side boundaries are taken as 1.0L (main hull) each, the domain volume is subdivided into various sub volumes in order to obtain structured multi-block grid as shown in figure (3).

Three different mesh sizes are evaluated in this study, coarse grid of 275,220, medium grid of 400,620 and a find grid of 427,940. Analogous results were obtained for the total resistance R_T as shown in table (2), where the difference $\Delta R_T\% = (R_T^{CFD} - R_T^{exp})/ R_T^{exp}$.

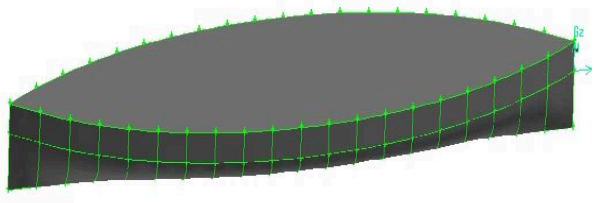

Fig. 2 Geometry of the hull model

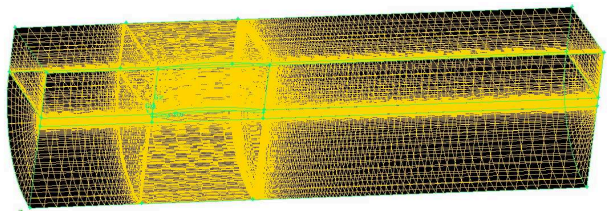

Fig. 3 Meshed domain volume in gambit

The grid generator *gambit* was used for meshing the computational domain with structured hexahedral grid. Unstructured tetrahedral was not chosen since this type of mesh reduces accuracy and increases the computational cost despite the fact that it is easy to handle while dealing with complex geometry [6].

Boundary Conditions and Solution Parameters

Assumed boundary conditions were of pressure inlet and pressure outlet for the inflow and outflow surfaces respectively, while the flow velocity is considered equal to the experimental velocity of the model. The non-slip condition is used on the hull, sides and top of boundary. Symmetry condition is invoked on the symmetric plane.

The commercial finite-volume software *fluent* is used for computations in this study. Since the motion of the free-surface is governed by gravitational and inertial forces, therefore, gravity effects must be taken into account in boundary conditions. Thus the variables and properties in any given cell are either purely representative of one of the phases, or representative of a mixture of the phases, depending upon the volume fraction values. The turbulence models of SST k-ω with standard coefficients are employed in the calculations. Convergence of the solution is assessed by monitoring the residuals of continuity, velocity, turbulence, volume fraction and drag force. The residual convergence criterion is taken as $1e^{-07}$ [7].

Resistance Calculations

The total resistance of the *wigley hull* (4m) is calculated. The calculations are carried out for *Froude number* ranging from 0.10 to 0.40. The calculated drag on the hull is recorded every 100 iterations, in order to judge the convergence of the solution.

TABLE 2. THE COMPARISON OF EXPERIMENTAL AND CFD RESULTS FOR WIGLEY HULL 4M

F_n	R_T (N) (Experimental)	R_T (N) (Software)	ΔR_T (%)	Fn	R_T (N) (Experimental)	R_T (N) (Software)	ΔR_T (%)
0.32	23.3478	22.636	3.048681	0.37	30.44043	31.548	-3.63848
0.32	23.3478	24.808	-6.25412	0.37	30.44043	30.264	0.579591
0.32	23.3478	23.72	-1.59415	0.38	33.19704	31.944	3.774553
0.35	26.55567	25.57	3.711712	0.38	33.19704	33.824	-1.8886
0.35	26.55567	27.546	-3.72926	0.38	33.19704	32.798	1.202035
0.35	26.55567	26.536	0.074071	0.4	40.1229	38.296	4.55326
0.37	30.44043	29.564	2.879164	0.4	40.1229	39.208	2.280244
0.37	30.44043	31.548	-3.63848	0.4	40.1229	38.728	3.476568

The results of the total resistance for *wigley hull* (4m) as a function of the *Froude number* are shown in Figure (4). The experimental results are extracted from the NMRI report [8]. For mesh study, resistance calculations for the three grids are carried out for higher Froude numbers; the turbulence model used in these calculations is SST k-ω. The coarse and medium grid results are in very close agreement. The difference between the medium and fine grid is relatively larger, although still acceptably small.

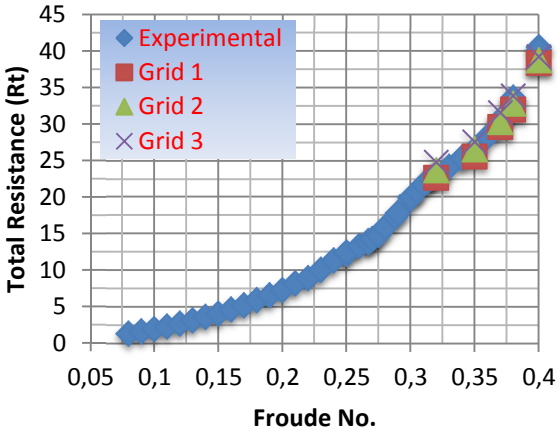

Fig. 4 Resistance curve for wigley hull (4m) comparing three different sized grids

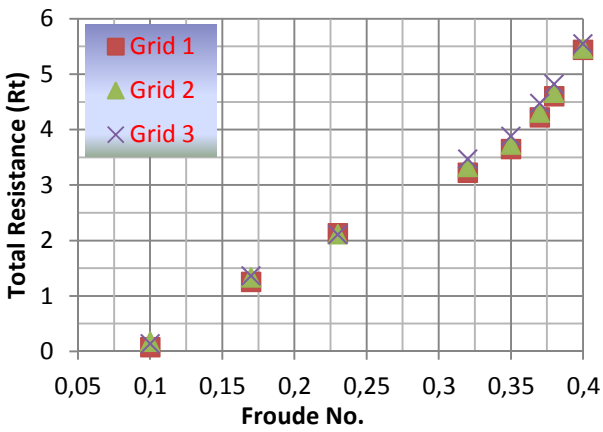

Fig. 5 Resistance curve for wigley hull (2m) comparing three different sized grids

The comparison of results obtained from different mesh sizes indicates that the difference ΔR_T% is too small and acceptable as shown in table (2). Also the difference ε = (medium - coarse) / (fine - medium), where 0< ε <1 is small and acceptable as shown in table (3).

TABLE 3. THE COMPARISON OF EXPERIMENTAL AND CFD RESULTS FOR WIGLEY HULL 4M AND 2M

Fn	R_T (N) (Exp.)	R_T (N) 4 m (Calculated)			ε_{4m}	Fn	R_T (N) 2 m (Calculated)			ε_{2m}
		Grid 1	Grid 2	Grid 3			Grid 1	Grid 2	Grid 3	
0.32	23.3478	22.636	23.72	24.808	0.996324	0.32	3.218	3.324	3.466	0.746479
0.35	26.55567	25.57	26.536	27.546	0.956436	0.35	3.646	3.728	3.876	0.554054
0.37	30.44043	29.564	30.264	31.548	0.545171	0.37	4.22	4.304	4.47	0.506024
0.38	33.19704	31.944	32.798	33.824	0.832359	0.38	4.596	4.66	4.816	0.410256
0.4	40.1229	38.296	38.728	39.208	0.9	0.4	5.438	5.456	5.548	0.195652

The total resistance of the *wigley hull* (2m) is calculated using the same mesh sizes under the same conditions. The calculations are carried out for Froude number ranging from 0.10 to 0.40. The calculated drag on the hull is recorded and plotted as shown in figure (5) in order to judge the convergence of the solution. The close agreements between the numerical predictions show that the overall numerical scheme is suitable for resistance prediction. The difference **ε** is small and acceptable as shown in table (3). Also coefficient of residual resistance (Cr) is calculated for both *wigley hull* and the difference of the predicted resistance coefficient is very small and of the same order of magnitude. This means the linear free-surface boundary conditions adequately describe the flow for this hull form.

Finally Contours for free surface wave and volume fraction (water) for both of *wigley hull* at various *Froude number* are shown in figure (6) and figure (7) respectively.

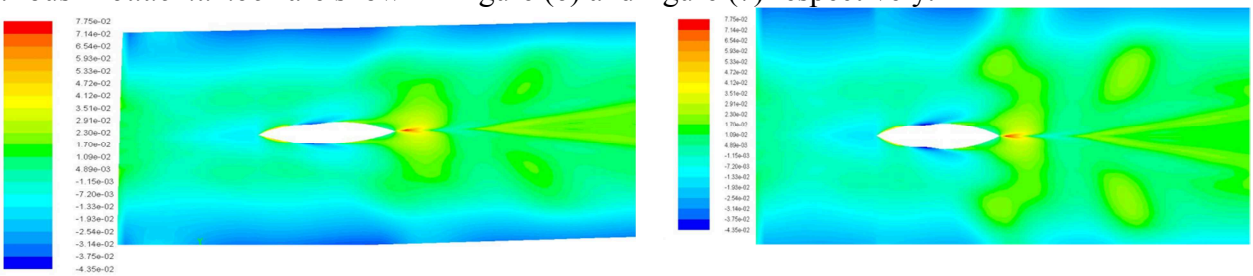

Fig. 6 Free surface wave contours for wigley hull at Fn=0.40 for 2m and 4m respectively

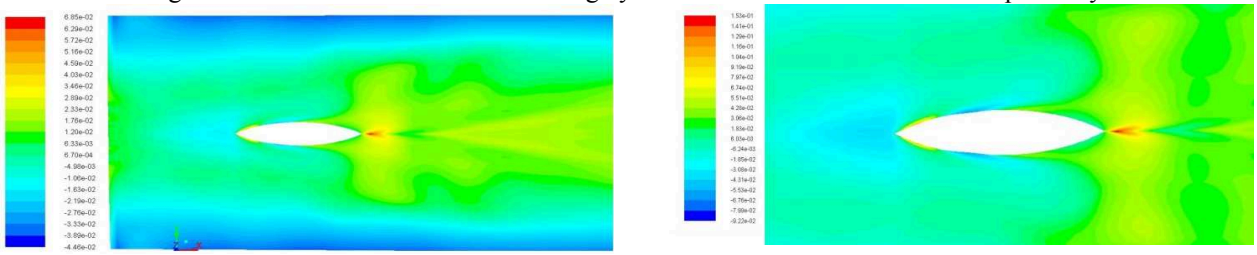

Fig. 7 Free surface wave contours for wigley hull at Fn=0.37 for 2m and 4m respectively

Conclusion

The *wave glider* is a surface vehicle with an attached sub-surface wing system which propels the surface component forward, negating the need for a motor. In this study a *wigley hull* form (4m) used as the floating hull has been investigated in order to predict the fluid flow of the ship using *CFD*. Calculations for total resistance are carried out for Froude numbers in the range of 0.10 to 0.40. *Gambit s*oftware is used for geometry creation and generation of mesh. *Fluent* software is used to calculate the total resistance of *wigley hull*. Three different mesh sizes are used in this study to calculate the mesh effects. The results obtained from *CFD* calculations for total resistance are compared with the experimental results for accuracy of the solution parameters. The comparison shows a good agreement between experimental and *CFD* results for wigley hull (4m).

In this paper we present a new method for computing the flow around a ship based on comparing the numerical predictions for *wigley hull* form (2m) with *wigley hull* form (4m) using the same mesh sizes under the same conditions in an attempt to design the floating hull of *wave glider* . The results obtained from *CFD* calculations are compared for accuracy of the solution parameters and

the method is useful and acceptable. Finally, a good agreement in results is found which shows the importance of CFD applications in calculating fluid flow to design the floating hull of *wave glider*.

Keywords: drive systems, bifurcation, chaotic behavior.

Abstract: The paper is focused on analysis of dynamic properties of drive systems. It describes the possible ways of stability analysis and possible ways of analysis of bifurcation of steady states and possible occurrence of chaotic behavior.

Introduction

Stability analysis can not be omitted when examining the dynamic properties of drive systems. In case of nonlinear systems and its models one can also expect occurrence of chaotic movements. The approach towards the analysis of its occurrence possibilities will be different when analyzing models with one or a few degrees of freedom or models of real technical systems. Those problems are addressed in the contribution [1].

Occurrence of chaos in drive systems and its modelling

Dissipative dynamic system can be characterized as systems whose behaviour with increasing time asymptotically approaches steady states if there is no energy added from the outside. Such system description is possible with relatively simple nonlinear equations of motion. For certain values of parameters of those equations the solution does not converge towards expected values, but chaotically oscillates. Strong dependency on small changes of initial conditions occurs as well. When analyzing such phenomena its mathematical essence can be connected with existence of “strange attractor” in phase plane. Possible creation of chaos can be seen in repeated bifurcation of solution, with so called cumulation point behind which the strange attractor is generated. Phase diagram of system solution then transfers from stable set of trajectories towards new, unstable and chaotic set. Creating the global trajectory diagrams is of essential importance. When succesfull, the asymptotic behavior of systems model is described.

Global behaviour of model of dissipative system

The problems of drive systems analysis belong into the most discussed problem of current engineering practice. There is still a number of conceptual and methodical questions which require further and mainly deeper understanding and explanation. One of those is the existence of deterministic chaos. And mainly the problem of deterministic chaos, its identification (and expectation) are described in this contribution [2].

Such system when nonlinear can be extremely sensitive on small changes of initial conditions or certain design parameters. A typical example would be a clearance in drive systems. In the chaotic case the solution becomes unstable and new solution appears, unstable and diametrically different. In the case of the presentation of the computational results in phase plane the transition appears from stable set of trajectories towards new, unstable (chaotic trajectories). It is clear that it is extremely important to understand the parameters areas in which the chaotic phenomena can occur mainly with controlled systems and/or with systems containing subsystems of different physical nature.

The changes in number of solutions of corresponding equation of motion depending on the change of a single variable (when all other variables remain constant) is called bifurcation. The importance of bifurcation diagrams is in the possibility to show the area of dynamic system parameter for which the system behavior is chaotic [3]. On of the possible approaches of bifurcation diagram construction is in following steps:

- select one parameter which is considered bifurcation from the set of technical parameters characterizing the properties and behavior and determine the interval of such parameter change
- perform the solution of system of equations which describe the system under consideration (or its model) depending of the particular value of bifurcation parameter
- change the value of bifurcation parameter for sufficiently low value
- repeat the above described steps until the full interval of bifurcation parameter is fulfilled draw bifurcation diagram where each partial calculation corresponds to a single point.

Sample model of drive system

We selected a simple drive system for verification of theoretical conclusions from last chapter. The model of the system is on Fig. 1. This system represents a machine unit consisting of drive element and a work element coupled to each other by stiff clutch. This clutch does not have linear characteristic. The characteristic is nonlinear and its diagram is on Fig. 1 too.

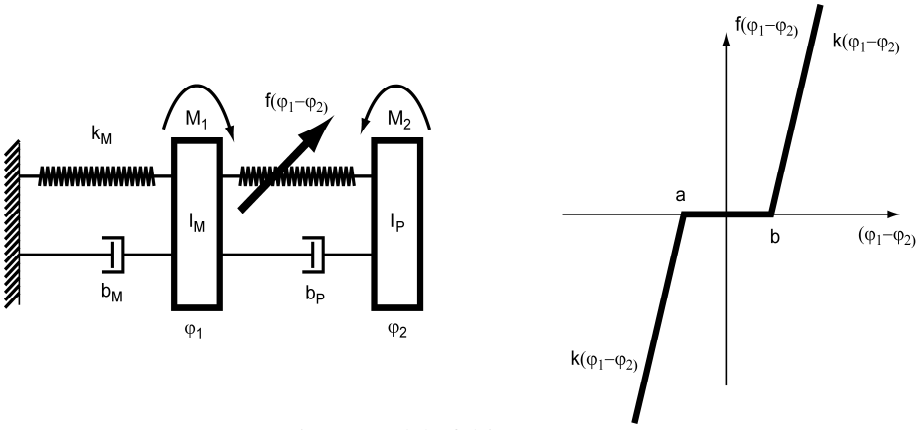

Fig. 1. Model of drive system

System equations of motion can be written in form:

$$\begin{aligned} &I_M \cdot \ddot{\varphi}_1 + k_M \cdot \varphi_1 + f_{(\varphi_1,\varphi_2)} + b_M \cdot \dot{\varphi}_1 + b_p \cdot (\dot{\varphi}_1 - \dot{\varphi}_2) = M_M + M_1^M \cdot \cos(\omega \cdot t) \\ &I_P \cdot \ddot{\varphi}_2 - f_{(\varphi_1,\varphi_2)} + b_P \cdot (\dot{\varphi}_1 - \dot{\varphi}_2) = M_P - M_1^P \cdot \cos(\omega \cdot t - \nu) \end{aligned} \tag{1}$$

where nonlinear function $f_{(\varphi_1,\varphi_2)}$ is defined by

$$\begin{aligned} &f_{(\varphi_1,\varphi_2)} = k \cdot (\varphi_1 - \varphi_2) \quad for \quad (\varphi_1 - \varphi_2) < a \\ &f_{(\varphi_1,\varphi_2)} = 0 \quad for \quad a < (\varphi_1 - \varphi_2) < b \\ &f_{(\varphi_1,\varphi_2)} = k \cdot (\varphi_1 - \varphi_2) \quad for \quad (\varphi_1 - \varphi_2) > b \end{aligned} \tag{2}$$

Lets analyze the case of symmetrical clearance, when $|a| = |b| = a$. Then for $|\varphi_1 - \varphi_2| \le a$ following equations hold

$$\begin{aligned} &I_M \cdot \ddot{\varphi}_1 + k_1 \cdot \varphi_1 + b_M \cdot \dot{\varphi}_1 + b_p \cdot (\dot{\varphi}_1 - \dot{\varphi}_2) = M_M + M_1^M \cdot \cos(\omega \cdot t) \\ &I_P \cdot \ddot{\varphi}_2 + b_P \cdot (\dot{\varphi}_1 - \dot{\varphi}_2) = M_P - M_1^P \cdot \cos(\omega \cdot t - \nu) \end{aligned} \tag{3}$$

and for $|\varphi_1 - \varphi_2| > a$ the following equations hold

$$\begin{aligned} I_M \cdot \ddot{\varphi}_1 + k_1\varphi_1 + k \cdot (\varphi_1 - \varphi_2) + b_M \cdot \dot{\varphi}_1 + b_p \cdot (\dot{\varphi}_1 - \dot{\varphi}_2) &= M_M + M_1^M \cdot \cos(\omega \cdot t) \\ I_P \cdot \ddot{\varphi}_2 + k \cdot (\varphi_1 - \varphi_2) + b_P \cdot (\dot{\varphi}_1 - \dot{\varphi}_2) &= M_P - M_1^P \cdot \cos(\omega \cdot t - \nu) \end{aligned} \quad (4)$$

Results

These parameters were obtained in MAXON MOTOR catalogue. DC motors represent both drive and work element.

The numerical simulations were performed for these parameters. Angular velocity of excitation was selected as parameter to change, in interval from 1 rad/s to 200 rad/s. The angular displacement and angular velocity of the system was calculated for phase plane and attractors projection. The excitation in the clutch must be calculated as well for attractors projection.

The phase plane for both angular displacement and for relative angular displacement is drawn. The Poincarre map and attractor for relative angular displacement were solved and drawn too. Another possibility of system analysis is to transfer angular displacements into frequency domain and perform the analysis in this domain. The FFT from relative angular displacement was calculated and analyzed.

Next pictures show all of earlier discussed schemes for excitation angular velocity ω = 18.93 rad/s, ω = 110 rad/s. These angular velocities were chosen as representative's values. The changes in dynamic system evolution depend on chosen parameter changes. On the spectrum of relative angular displacement you can see it very well. Although the structure of the system does not change and one parameter changes only, in the spectrum you can see many natural frequencies. These frequencies appear and disappear with the changes of angular velocity ω. Phase planes also have different shapes. Poincarre maps are interesting for analysis as well. Here we can discover typical diagrams known from theoretic studies, as stable focus for ω = 110 rad/s, see Fig. 9. The system is closest to the chaotic behavior for ω = 18.93 rad/s. The high dumping in the system protects the creation of fully chaotic behavior, instead relaxation oscillation occurs.

Conclusion

Chaos and other statements of nonlinear systems became phenomenon in variety of engineering problems in last years. Therefore we focused on it also in analysis of drive systems. Based on performed analysis we can state following recommendations:

- when evaluating the properties and behavior of dynamic system it is useful to define such parameters of models, which can influence the occurrence of parasitic motion including chaotic one (fluctuation of initial conditions, links gaps, control parameters),
- to observe the evolution of responses in phase planes based on changes of selected parameters and to identify typical chaos effects,
- if such effect occur then evaluate Fourier spectrum of responses. Chaotic motion corresponds to broadband spectra, even when exciting spectra is narrowband.

With respecting given recommendations it is not difficult to identify the areas of possible occurrence of chaos in technical systems using mathematical modelling. However, we do not want to disvalue the analytical approaches with above described alternative approach.

Keywords: mine exploration robot; material selection; flameproof enclosure; finite element analysis

Abstract：This paper focuses on materials selection and finite element analysis for flameproof enclosure of mine exploration robot. The internal environment of abandoned mine is unknown, thus the robot must be designed explosion proof. This research deals with a safe solution to environment exploration for abandoned mines by using mine exploration robot. Modeling by using 3D software and finite element analysis verifies whether enclosure strength satisfies requirements. It will provide a reference for the development of mine exploration robot.

Introduction

In the process of mining, a large number of goaves were formed. The area of coal mine goaves formed each year can be hundreds of millions cubic meters [1]. Comprehensive development and utilization of abandoned mine becomes the new world topic of resources recycle. In the middle of the 20th century, the developed countries began to study on how to handle with abandoned mines, for instance, the Netherlands has built a new type geothermal power station by using geothermal resources in an abundance mine. In China, although there are few applicable examples, it has drawn great attention. Reusing abandoned mines is necessary and useful from the perspective of environmental protection and resources comprehensive utilization [2-4].

For ecological reconstruction and utilization of abandoned mines, it is necessary to work out reasonable measures, and to explore the internal environment of abandoned mines. The underground temperature and the concentration of toxic gases can also cause danger to underground workers or researchers. Thus there is a need to do research on mine exploration robot which can replace workers or researchers into mines to explore mine temperature and gas concentration. This kind of robot will be a powerful tool for researchers, and this research is of great practical significance.

Because of the unknown and dangerous environment underground, in addition to the requirement of flexibility, high reliability and obstacle avoidance ability, mine exploration robot must also have flameproof design. With reference to national standards GB3836.1-2000, it is suitable to adopt flameproof design on the main body of small mine exploration robot. Electrical equipments which may easily generate electrical arc or spark will be placed inside the flameproof enclosure.

This paper introduces the structure design of abandoned mine environment exploration robot based on the Chinese and foreign research status of mine robot. It focuses on the design of flameproof enclosure and finite element analysis.

The Development Status of Mine Exploration Robot

Chinese and foreign research on mine exploration robot has made some achievement, and some robots are designed for flame proof. For example, the rescue and exploration robot of Remotec Co., Ltd., named V2, has the ability of moving in dangerous mine environment. V2 is propelled by explosion-proof motors that drive rubber tracks. V2 has combines overall flameproof design with

partial explosion-proof design [5].CUMT-1, developed by China University of Mining and Technology, is the first coal mine robot for rescuing. It is equipped with low luminous camera, thermometer and toxic gas sensor. CUMT-1 can transmit live information including images, concentrations of gas and dust and temperature at the scene through a wireless network to operator. The main body is designed to adopt flameproof enclosure [6, 7].

The Structure Design of Mine Exploration Robot

Abandoned mine exploration robot mainly consists of three parts: six-wheeled mechanism, synchronous belt transmission and flameproof enclosure, as shown in Fig.1. It has the characteristics of compact structure, good mobility and high transmission efficiency.

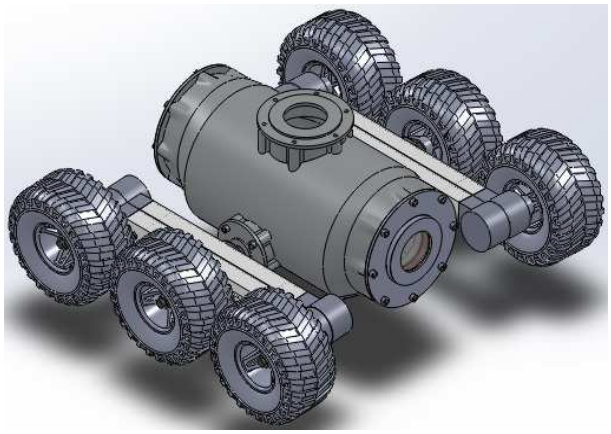

Fig.1 3D Model of Mine Exploration Robot

The flameproof enclosure of mine exploration robot is not only the robot chassis, it also need enough space for installing electrical equipments, such as control and communication module and power module [8]. When the explosive mixture gases, from environment into the enclosure, are ignited by spark or ack in the enclosure, the enclosure should not be destroyed, and the explosive gases from the environment outside the enclosure should not be detonated [9, 10]. Therefore, the robot flameproof enclosure should have enough strength and installation space. In addition, under the circumstance of same volume, volume of different shapes has an effect on explosion pressure [11].

Table 1 shows that the pressure of rectangle container and cylindrical container is small. But cylindrical container has advantages of even stress, simple structure and compact inside, compared with rectangle container [12]. Therefore, this research adopts cylindrical shape for robot body structure, and for the requirement of robot mobile performance, the enclosure bottom is designed as flat. The shape of enclosure is similar to cylindrical.

TABLE 1 THE EXPLOSION PRESSURE UNDER THE SAME VOLUME OF DIFFERENT SHAPE OF PRESSURE VESSEL

Shape	Volume /L	Pressure /Mpa (CH_4 9%-10%)
Cuboid	8	0.51
Cylinder	8	0.55
Cube	8	0.61
Sphere	8	0.71

Enclosure Material Selection

The enclosure of mine exploration robot should not only have enough strength, it should also has light weight to improve robot mobility. Robot flameproof enclosure can be aluminum ally casted. Because dangerous mechanical collision spark and friction spark may be easily generated when aluminum alloy contains large amount of magnesium (Mg), the amount of Mg cannot exceed a certain standard. Chinese standard is less than 0.5%. This research finds out that the tensile strength of the

enclosure material of an electric drill used in coal mine, named ZA1Zn11Si7 (code name: ZL401; Mg 0.1%-0.3%) , is greater than 195Mpa. This kind of alloy has good casting performance, and is suitable for vessels under pressure.

Flameproof Enclosure Finite Element Analysis

The design pressure of flameproof enclosure of mine exploration robot is mainly related to explosion pressure. If the volume of vessels is fixed, the gas pressure after explosion can be expressed in Equation 1： $p_1 = p_0(273 + t_1)/(273 + t_0)$ (1)

In Equation 1:

p_0 refers to the pressure of mixed gas before explosion: generally $1*10^5$pa;

t_0 refers to the temperature before explosion: generally 15-17 ℃;

p_1 refers to the pressure of mixed gas after explosion;

t_1 refers to the temperature after explosion: taking1850-2650 ℃.

The calculation result of Equation 1 suggests that p1 is 0.732-1.015Mpa.

A large number of experiments conclude that the pressure caused by explosive gas explosion is usually at 0.703-1.01Mpa. Thus the design pressure value is made as 1.01Mpa [13, 14]. According to Chinese National Standard GB3836.2-2000, this research carried out enclosure static pressure experiment, and the analysis type is static. In addition, because the minimum thickness of aluminum made cylindrical pressure vessel is 3mm, and in consideration of mine corrosion allowance, the thickness of robot enclosure is made as 5mm.

This research carries on modeling and finite element analyzing by using Solidworks software [15], which is a 3D software. The analysis result comes up after initialization settings and calculation. As shown in Fig.2, the maximum stress appears in the middle of the bottom, and safety coefficient is less than 1.5. Thus it does not meet the requirement. This research increases the thickness of bottom to 8mm. It can be seen in Fig.3, the maximum stress is 130.4Mpa which is less than the tensile strength of materials used, the weakest part of the enclosure is on the border between the enclosure and the above lid. The minimum safety coefficient is 1.5, and it satisfies the requirement.

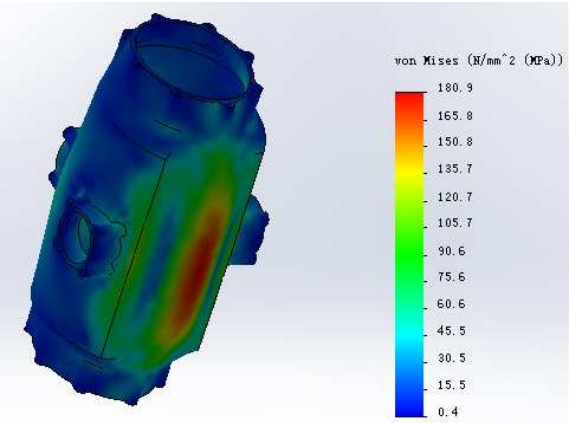

Fig.2 Static Analysis Diagram (a)

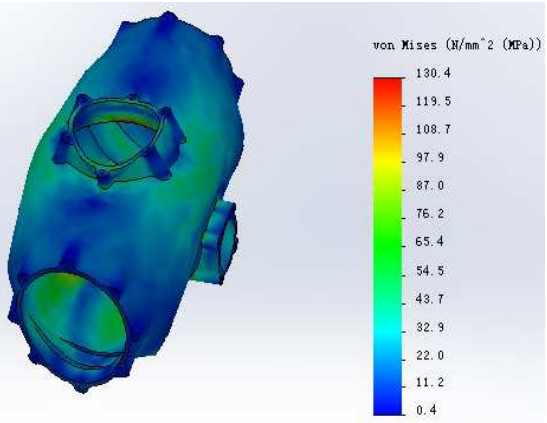

Fig.3 Static Analysis Diagram (b)

Based on the foregoing content of robot structure design, enclosure material selection and finite element analysis, and by adopting electrical explosion-proof standards and assembly requirements, this research made out a prototype of mine exploration robot. Fig.4 shows the prototype.

Fig.4 The Prototype of Mine Exploration Robot

Conclusions

With the development of economy, there are more and more abandoned mines. Therefore, the operation and utilization of abandoned mine is imperative. Firstly, this paper explains the research significance of mine exploration robot. Due to the uncertain mine environment, exploration robot will replace researchers to explore the environment of mines in avoidance of injury. Secondly, this paper designs the robot to be flameproof, and adopts light alloy materials for enclosure. Finally, it carries out static analysis by finite element analysis software, and verifies that the flameproof enclosure satisfies strength requirement. It provides a reference for future mine robot safety design.

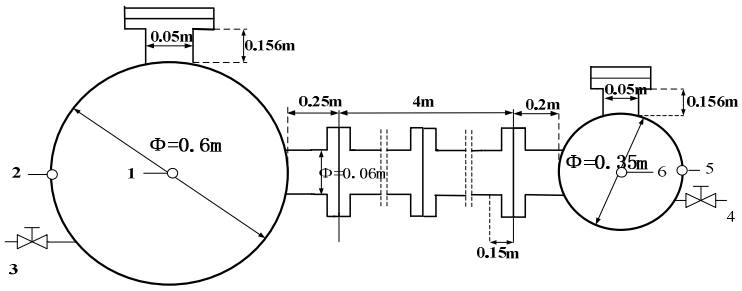
Keywords: linked vessels; gas explosion; closed explosion; vented explosion; initial pressure; peak pressure

Abstract：An experimental study on pressure evolution during closed explosion and venting progress of methane–air mixtures ([CH_4=10%]) in linked vessels was performed, for systems at various initial pressures (P_0=0-0.08MPa). The effects of initial pressure on regularity of pressure variation in vessels were discussed. For the closed explosion in isolated vessel, the higher level of the initial pressure in isolated big vessel is, the larger the peak pressure and rate of pressure rise is, and the peak pressure increases nonlinearly with initial pressure; For closed explosion in linked vessels, the higher initial pressure within the linked vessels system leads to the higher peak pressures in two vessels and there is an approximate linear relationship between them, which is similar to explosion in isolated vessel. For vented explosion in linked vessels at higher initial pressure, venting has poorer effect on protection of the linked vessels.

Introduction

Linked vessel configuration handling or storing flammable gas is very common in industry (linked reactors and tanks, mines, electrical equipment casings, adjacent buildings)[1]. Once explosion takes place in one vessel, it can propagate to other vessels through linked pipes, which leads to higher value of peak pressures and rates of pressure rise in the vessels as compared to the explosion in isolated vessel. The term pressure-piling was often used to describe this phenomenon.



Pressure-piling in linked vessels was first recognized as a special explosion hazard in 1906[2], and then some comprehensive experiments were reported in literatures. These experiments demonstrate that pressure-piling is strongly influenced by ignition position, pipe diameter, volume ratio of the two vessels[3-6]. Some authors[1,7] established and developed CFD model to model gas explosions in linked vessels, aiming at investigating the effect of the ignition position, the pipe diameter and the volume on linked vessel explosion. These efforts have been contributed to guide the protection against explosion hazard in linked vessels. However, some other parameter such as intinal pressure may be significant to safety design of linked vessels. What's more, there are few reports on vented explosion of linked vessels at higher initial pressure.

In this work, the effect of initial pressure on the closed and vented explosion characteristics in a linked vessels experiment system was investigated.

Experimental apparatus

The apparatus used in the present experiments is illustrated in Fig.1. It consists of two spherical vessels: 0.113 $m^3$and 0.022 m^3 (referred as big vessel and small vessel respectively) which were linked by cylindrical pipe of 4 m. The area of each vent is 1.96×10^{-3} m^2 (D=0.05 m).

During the experiments, linked vessels system was filled with 10% methane–air mixture at ambient initial temperature and various initial pressures. The pressure variation was recorded using a series of high-frequency pressure transducers. The position of interface for pressure transducer and gas inlet were shown in Fig.1. Ignition using a standard 6J inductive-capacitive spark was positioned at the two vessels center (see Fig1).The pressure signals were monitored with a data acquisition system DEWE 4.3.

Position 1, 14,——ignition； 3, 4——gas inlet；2, 5——pressure transducer；

Fig.1 Schematic diagram of explosion in linked spherical vessels

Results and discussion

Effect of initial pressure on gas explosion in isolated big vessel

The pressure history and peak explosion pressures of CH_4-air mixtures at various initial pressure is shown in Fig 2 and Fig 3 respectively. As shown in the Fig 2 and Fig 3, the explosion pressure and the rate of pressure rise increase with the increasing initial pressure. And the peak explosion pressure is correlated to initial pressure by the linear equation： $P_{max}=7.6315P_0+0.681$. With regard to closed explosions in isolated vessel, the present data, as well as some previous data[8-10] show a common feature: there is a linear relationship between the peak pressure and the initial pressure. With the increase of the initial pressure, the vessel has more flammable gas, more abundant the energy is released, which leads to the higher peak pressure. And with the increase of the initial pressure, the distance between the molecules is closer, probability of activated molecular collision is bigger, which accelerates the reaction rate and urges the rate of pressure rise to increase

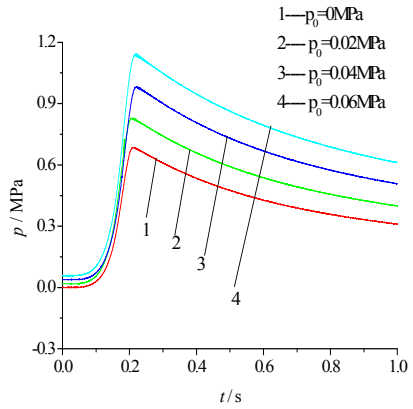


Fig.2 Pressure histories in the vessel at different initial pressure

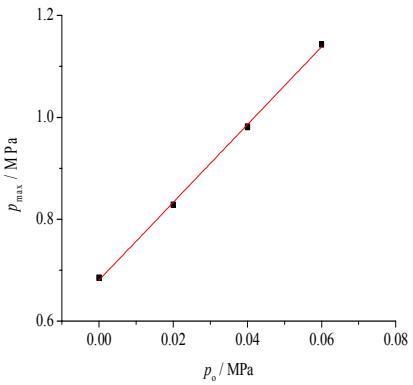

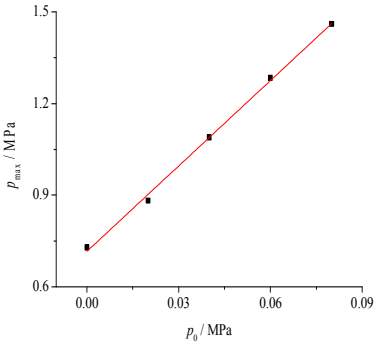

Fig.3 The fitting curve of peak pressure at different initial pressure

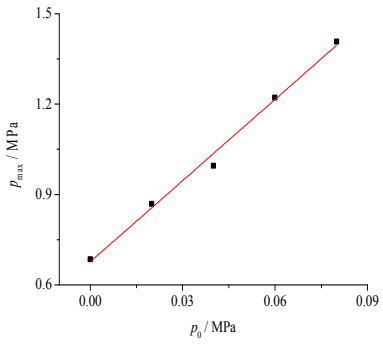

Effect of initial pressure on closed explosion of linked vessels

Fig.4 and Fig.5 illustrate peak pressures in two vessels connected by 4.45 m linked pipe, for ignition in the small vessel center and the big vessel center, respectively, by varying the initial pressure. As displayed in Fig.4 and Fig.5, initial pressure has significant effect on the peak pressures in two vessels; the higher initial pressure within the linked vessels system leads to the higher peak pressures in two vessels. There is an approximate linear relationship between them, which is similar to explosion in isolated vessel.

The linear equations for the peak pressure and initial pressure are listed in Table 1 and Table 2. As presented in Table 1 and Table 2, for ignition in the small vessel center, the slopes of linear relationship between peak explosion pressures in the two vessels and initial pressure is almost the same as that obtained in the isolated vessel. For ignition in the big vessel center, the slope of linear relationship between peak explosion pressure in the big vessel and initial pressure is almost the same as that obtained in the isolated vessel, however, the slope of linear relationship between the peak pressure in the small vessel and initial pressure in linked vessels system is larger as compared to that in isolated vessel, and the former slope is about twice the latter. Therefore, compared to the isolated vessel's explosion, the peak pressure in the small vessel is sensitive to variation within system initial pressure, while igniting in big vessel.

Effect of initial pressure on vented explosion of linked vessels

Fig.6 illustrates pressure histories of closed explosion and vented explosion of two vessels connected by 4.45 length linked pipe, for ignition in big vessel center and at 0.06 MPa initial pressure. For vented explosion experiment, safety membranes (the membrane rupture pressure is 0.28 MPa) are used to cover the vents. As compared to closed explosion, the peak pressure in big vessel drops from 1.08 MPa to 0.98 MPa and the peak pressure in small vessel drops from 1.91 MPa to 1.86 MPa, which suggests that there is few difference in peak explosion pressure between closed explosion and vented explosion of linked vessels. In this case, for peak explosion pressure, venting can't get the expected effect for linked vessels system at higher initial pressure. However, as shown in Fig.6, compared to closed explosion, the pressures in the two vessels quickly decrease after reaching peak pressures without oscillation process, so venting can reduce impulse acting on the two vessels. Because of methane–air mixtures in linked vessels burned out and cooling effect of vessel wall, as well as discharging of the high temperature and high pressure products from the vent increase the rate of pressure decline in two vessels.

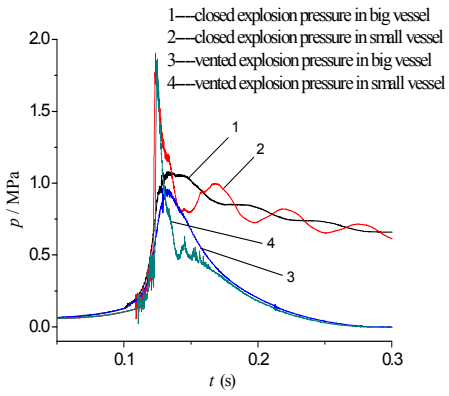

Fig.6 Effect of initial pressure on linked vessels venting process

Conclusions

Through experiments and theoretical analysis, following conclusions about the effects of initial pressure on gas explosion in linked vessels can be drawn.

(1) For closed explosion in isolated vessel: the higher level of the initial pressure in isolated big vessel is, the larger the peak pressure and rate of pressure rise is, and the peak pressure increases nonlinearly with initial pressure

(2) For closed explosion in linked vessels: the higher initial pressure within the linked vessels system leads to the higher peak pressures in two vessels and there is an approximate linear relationship between them; compared to the isolated vessel's explosion, the peak pressure in the small vessel is sensitive to variation within system initial pressure, while igniting in big vessel..

(3) For vented explosion in linked vessels: for linked vessels system at higher initial pressure, there is few difference in peak explosion pressure between closed explosion and vented explosion of linked vessels. However the pressures in the two vessels quickly decrease after reaching peak pressures without oscillation process, so venting can reduce impulse acting on the two vessels

Key words: transverse flux permanent generator; response surface method; center combination design; optimization design

Abstract: To consider the complicated situation fully such as saturation, leakage flux and so on, and to make the generator size to meet the design requirements, we use the methodology of response surface method combined with center combination design to optimize the transverse flux permanent generator. At first, the optimization goals and the optimization design variables are set on the basis of the finite element model in the initial design. Then an optimized design model of the generator is built by the variable sequential combination response surface methodology. Experiment is arranged by the center combination design methodology, and optimal parameters are selected through response surface method. At last, we get all the structural dimensions of transverse flux permanent generator. The optimization makes the output voltage meet the design requirement.

Introduction

Transverse flux permanent generator is a special generator with high torque density. The generator is very promising in the field of direct-drive marine power system and ocean power generation system [1]. The concept of transverse flux permanent generator was raised by professor Herbert Weh, a generator expert of Germany Braunschweig University [2]. The generator uses a unique structure which solves the mutual restraint contradiction between the armature winding section and alveolar width in the traditional generator. At the same time it can improve the generator electromagnetism load, thus improve the ability of magnetoelectric energy conversion and it also has characteristics of small volume, light weight, wide speed range and controllability [3-6]. Resulting from the initial design of the generator often fails to effectively meet the design needs. In order to solve this problem, generator will introduce various correction coefficients based on magnetic circuit design in the traditional design process. Obviously, this method is time-consuming, cost of design is large and difficult to meet the needs of modern generator design. So in the modern generator design, in order to improve the accuracy of calculation, we use the finite element numerical calculation method and use the methodology [7] of response surface method combined with center combination design to optimize the transverse flux permanent generator.

Based on the initial design and practical optimization design requirements of transverse flux permanent generator, we raised the methodology of response surface method combined with center combination design to optimize the transverse flux permanent machine on the basis of the finite element model in the initial design. Eventually, we made the main parameters of generator output voltage is 223.2V.

Determination of the transverse flux permanent generator's optimization goals and optimization variables

We optimize the transverse flux permanent machine on the basis of the finite element model in the initial design. The maximum objective of transverse flux permanent generator is that the generator can provide to enough induction electromotive force. We analyze the generator's torque in terms of electromagnetic chain. Because the generator's each phase are the same, we analyze the condition of single phase.

In case of transverse flux permanent machine loading, a phase armature winding magnetic chain is

$$\Psi = \Psi_{PM} + \Psi_a = \Psi_{PM} + Li \tag{1}$$

Ψ -Total flux linkage of the winding, Ψ_{PM} -Flux linkage of permanent magnet effect, Ψ_a - Flux linkage of armature coils effect, L- The armature coil inductance, i- The armature coil current.

When the generator is running, excluding copper loss of the armature coil, the single-phase instantaneous electromagnetic power of generator can be expressed as:

$$p_m = -ei = \frac{d\Psi}{dt} i = \frac{d}{dt}\left(\frac{1}{2} Li^2\right) + \left(\frac{\partial \Psi_{PM}}{\partial \theta} i + \frac{\partial L}{\partial \theta} i^2\right)\Omega \tag{2}$$

p_m - Single-phase instantaneous electromagnetic power, θ - The mechanical angle of the generator rotor, Ω - The mechanical angular velocity of the generator rotor

In the formula (2), the first term is the inductive energy storage and it does not participate in electromechanical energy conversion of generator, so the instantaneous electromagnetic torque of generator is:

$$t_m = \frac{\partial \Psi_{PM}}{\partial \theta} i + \frac{\partial L}{\partial \theta} i^2 \tag{3}$$

The induced electromotive force is determined according to Faraday's law of electromagnetic induction and its size is proportional to the rate of change of the coil flux linkage, and its direction is determined by Lenz's law. Generator no-load induced electromotive force can be expressed as:

$$e_0 = -\frac{\mathrm{d}\Psi_{PM}}{\mathrm{d}t} = -\frac{\mathrm{d}\Psi_{PM}}{\mathrm{d}\theta}\Omega = -N\frac{\mathrm{d}\Phi_{PM}}{\mathrm{d}\theta}\Omega \tag{4}$$

e_0 - No-load EMF instantaneous value

We obtained some values by using finite element analysis and the no-load electromotive force under different speeds can be calculated by these values. Instantaneous induced electromotive force is close to the flux linkage waveform of generator, and the change of the flux linkage is determined by the change of excitation source and magnetic resistance of the main magnetic circuit. If we can get the appropriate kind of flux linkage waveform, the desired output induced electromotive force would be got. Optimizing tooth shape of rotor and stator can be achieved. So The optimization design variables of the transverse flux permanent generator are:

$$X = [x_1, x_2, x_3, x_4]^T = [h_{PM}, t_{PM}, r, l_e]^T \tag{5}$$

h_{PM} -The length of the permanent magnet magnetization direction.

t_{PM} - The radial length of permanent magnet.

r - The rotor tooth fillet radius.

l_e - Each pole core effective length of generator stator.

Optimal goal of transverse flux permanent generator:

$$E_0 = \sqrt{\frac{1}{T}\int_0^T e_0^2 dt}$$

E_0- No-load induced electromotive force valid values.

Optimization of rotor

The function relationship between the induced electromotive force and three rotor design variables (h_{PM}:x_1, t_{PM}:x_2 and r:x_3) is a curved surface. We use the second order response surface model to approximate it. For three design variables, CCD required fifteen tests. In CCD test, design variable range and level of three generator rotor design variables was shown in Table 1, among α=1.216. We got induced electromotive force data of different combinations of variables by using Ansoft Maxwell software to simulate.

TABLE 1 RANGE AND HORIZONTAL LEVEL OF CCD TEST DESIGN VARIABLES X_7, X_8 AND X_9

design variables of generator	Horizontal level				
	-α	-1	0	+1	-α
x_1 [mm]	3.568	4	6	8	8.432
x_2 [mm]	6.92	8	13	18	19.08
x_3 [mm]	0.96	1.5	4	6.5	7.04

According to the sample data of CCD, the estimated value of β was calculated by the least square method, and we can obtain fitting the response surface models of the induced electromotive force of three rotor design variables x_7, x_8, x_9. Response surface optimization diagram of induced electromotive force can be directly obtained by the response surface model. It is shown in Figure 1. The optimized rotor design variables (x_7, x_8 and x_9) are 6.3685mm, 13mm and 2.3725mm.

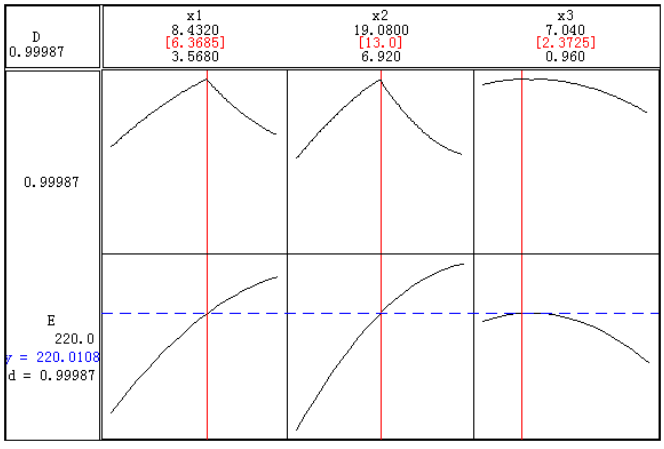

Fig.1 Response surface optimization diagram

The optimization of the stator

After determining the part of the rotor size, we optimized each pole core effective length l_e of generator stator. Figure 2 is corresponding changes of induced electromotive force when l_e is changing. As you can see from figure2, when l_e is extending from the middle position of the generator stator axial length (Stator teeth begin to overlap in axial direction), induced electromotive

force is increasing. However, when l_e reaches a certain length, induced electromotive force would be unchanged. This shows that l_e has no effect on induced electromotive force of the generator. So, optimization objective l_e can be achieved by the induced electromotive force(emf) is 47mm.

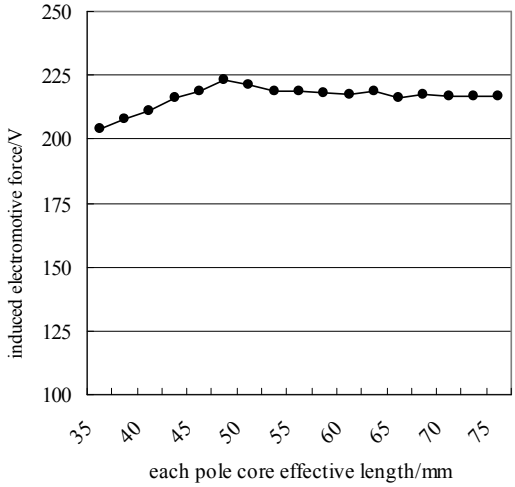

Fig.2 Effect change of each pole core effective length on the induced emf

Conclusion

So far all the structural dimensions of transverse flux permanent generator have been determined. The length of the permanent magnet magnetization direction is 6.3685mm, the radial length of permanent magnet is 13mm, the rotor tooth fillet radius is 2.3725mm and each pole core effective length of generator stator is 47mm. When number of coil is one, valid value of no-load induced electromotive force is 11.16V_{rms}. The figure 3 shows it. Output voltage equal to 20 times 11.16 V_{rms}. Eventually, we made the main parameters of generator output voltage is 223.2V. As the above optimal design process shown, we used electromagnetic field finite element analysis method to analyze, experiment was arranged by the center combination design methodology, and optimal parameters were selected through response surface method in the design of the generator stator and rotor structure size. All the structure sizes of transverse flux permanent generator are reasonable and meet requirements of the generator design.

Keywords: the lumped-parameter model; side impact; concept design phase; optimization

Abstract: In the process of side impact, the door was directly contacted with the chest, abdomen and pelvis of dummy and its movement has a large effect upon dummy injury. A evaluation about dummy injury influenced by the velocity and displacement of chest, abdomen and pelvis in dummy was proposed. A rapid forward development strategy which is applied in forward development was presented. A new type side impact LPM (Lumped-Parameter Model) was established. The stiffness of critical area in vehicle body was optimized by LPM which used the intrusive velocity and displacement of chest, abdomen and pelvis in dummy as design object. The example showed that the safety performance was improved obviously and the development period was shortened in some extent.

Introduction

In the progress of new car forward development, the detail finite model of new car cannot be established in the concept phase because of CAD data absence. However, LPM can be used for rapidly analyzing stiffness of vehicle body for achieving better new car safety performance, which plays a very important role in new car development based on same platform. In 1970, Kamal[1] developed a relatively simple but powerful model for simulating the crashworthiness response of a vehicle in full frontal impact. Lim, Green and Chevad[2-4] used LPM in full frontal impact, side impact and offset frontal impact analysis, the results were proved good. Zhao Kaishen and Shi Yuliang[5] from Qirui Co., Ltd used LPM for optimizing the stiffness of frontal critical area. The movement of door has a large effect upon dummy injury because it directly contacted with the chest, abdomen and pelvis of dummy. The intrusive velocity and displacement on chest, abdomen and pelvis were affected by stiffness of critical area in BIW (Body In White), which did not be researched formerly. In this paper, for improving side impact performance and shortening new car forward development period, a rapid forward development strategy that used new type side impact LPM for optimizing stiffness of critical area in BIW was proposed, which was applied in new car forward design based on same platform.

A rapid forward development strategy

During the concept phase of new car forward development, the traditional method is just put stiffness, modal and mass of BIW as performance assessment target. The crashworthiness

performance was out of consideration because of lacking detail CAD data. The disadvantage is that the potential of safety performance cannot be exploited completely in detail design phase. A rapid forward development strategy was proposed which used new type side impact LPM in new car based on same platform forward development. Take a new car forward development of a company as example, at first, the new type side impact LPM was established based on original platform FE (Finite Element) model. Then, the LPM accuracy was confirmed for optimizing the stiffness of BIW. At last, the optimum stiffness of BIW was outputted which optimized with LPM. The critical area structure of BIW was designed reasonable by this process flow and the development period can be shortened effectively.

Establishment of new type side impact LPM

In the progress of side impact, the injury of dummy was influenced by stiffness of BIW which maintain a sufficient survival space for occupants in crash. Properly side structures and doors design can minimize intrusion effectively. The goal of crashworthiness is an optimized vehicle structure that can absorb the crash energy by controlled vehicle deformations while maintaining adequate space so that the residual crash energy can be managed. Side structures were the main energy absorbed components in side impact. On the base of energy management, the side impact can be divided into six parts, MDB (Moving Deformable Barrier), Front door, Rear door, B pillar, Rocker, Rest of vehicle. For describing the intrusion of chest, abdomen and pelvis in dummy, the Front door was divided into outdoor and four parts of inner door. The detail description was as shown in Figure.1.

Figure.1 The division of Front door

For exploring the relationship between intrusion of chest, abdomen, pelvis in dummy and stiffness of side structure, the new type side LPM based on Ded [6]'s LPM was proposed by analyzing side impact mechanics. The topology of new type side impact LPM was as shown in Figure.2. The detail description of parameters in new type side impact LPM was illustrated in Table 1.

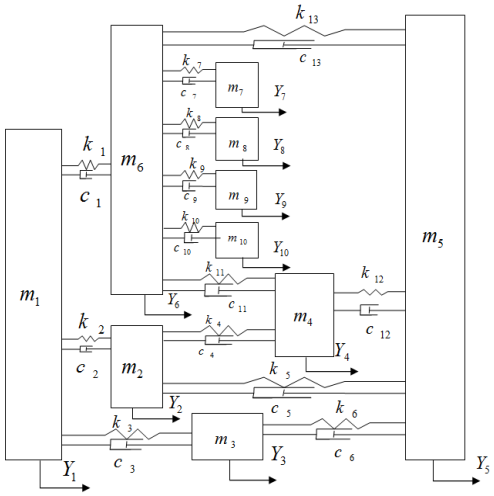

Figure.2 New type side impact LPM

TABLE 1 THE DESCRIPTION OF PARAMETERS IN NEW TYPE SIDE IMPACT LPM

Parameters	Description
m_1	MDB
m_2	Rear door
m_3	Rocker
m_4	B pillar
m_5	Rest of vehicle
m_6	Outdoor
$m_7 \sim m_{10}$	Four parts of inner door
$k_1 \sim k_{13}$	Stiffness
$c_1 \sim c_{13}$	Damping
$Y_1 \sim Y_{13}$	Displacement

The most important parameters in LPM were spring properties, which extracted from the results of FE simulation based on same platform. Take a forward development of new car which as a typical MPV in market as example, the finite element simulation model was developed (Figure.3). The FE model was built based on C-NCAP which includes the vehicle, MDB and dummy. The initial velocity of MDB is 50km/h. The experimental and numerical vehicle deceleration results at B pillar were illustrated in Figure.4.

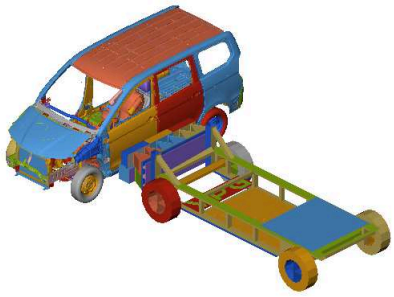

Figure.3 A finite element model of reference vehicle

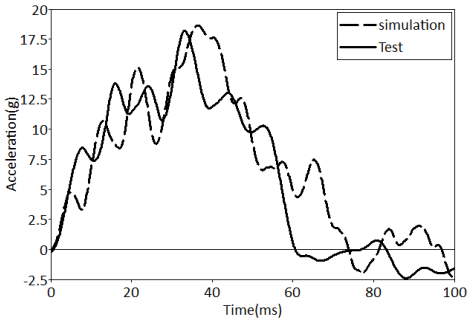

Figure.4 The vehicle deceleration comparison between test and simulation

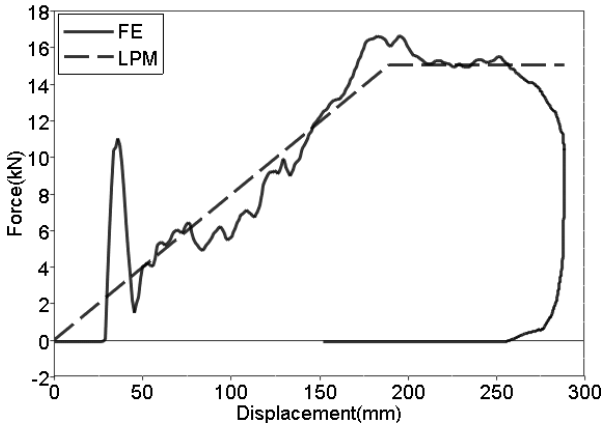
It is noticed that the spring properties in the LPM in Figure.3 represent interaction between a pair of subsystems. The spring characteristics of LPM were obtained by defining a number of contact and sectional forces in the direction of impact, which based on the least-squares error approximation of FE results. The displacement-time histories of subsystems are obtained by measuring serious points from results of FE model. One principle must be satisfied that the area enclosed between LPM stiffness curve and horizontal axis was equal to the FE's area. The idealized stiffness of MDB to Rocker subsystem was shown in Figure.5. For describing the damping affection between different subsystems, damping coefficients were defined by trial and error. The LPM parameters were summarized in Table 2.



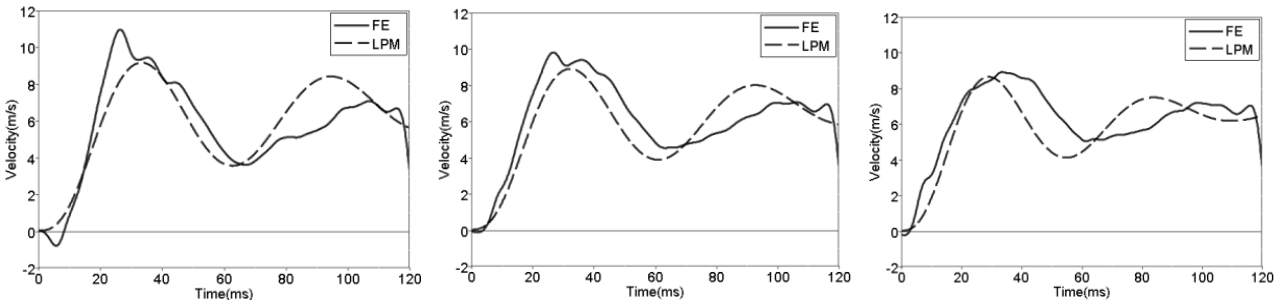


Figure.5 Idealized of behavior of spring between MDB to Rocker

TABLE 2 LPM PARAMETERS

Mass	Value (kg)	Damping	Value (kN.ms/mm)	Stiffness	Intrusion (mm)	Stiffness coefficient (kN/mm)	Yield force (kN)
m_1	960	c_1	0.5	k_1	212	0.2431	30.4
m_2	18	c_2	0.5	k_2	220	0.1207	20
m_3	17	c_3	0.5	k_3	288	0.0793	15
m_4	5.5	c_4	0.1	k_4	37	2.1621	28
m_5	1270	c_5	2.5	k_5	247	0.1336	30.1
m_6	14	c_6	2.5	k_6	154	0.1227	12.6

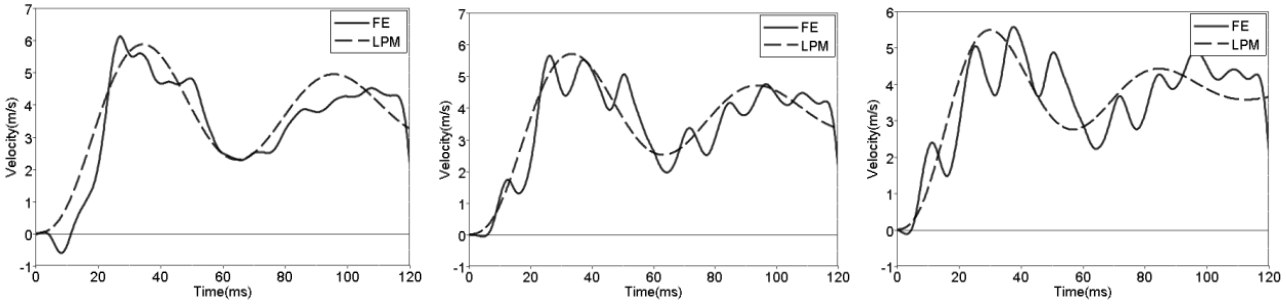
		c_{13}	2.5	k_{13}	232	0.3073	50.2

Validation of new type side impact LPM

For describing the movement of inner door, the Madymo model was established on the basis of LPM in Figure.4. The comparison of intrusive velocity and displacement of chest, abdomen and pelvis in dummy between LPM and FE were as shown in Figure.6. The relative errors between LPM and FE were given in Table 3 and the max error was not exceeded 20%.



(a) Chest (b) Abdomen (c) Pelvis

Figure.6 Comparison of intrusive velocities between LPM and FE at 50km/h

TABLE 3 RELATIVE ERROR BETWEEN LPM AND FE

	LPM	FE	Relative error (%)
Intrusion at Chest	208(mm)	224(mm)	7.1
Intrusion at Abdomen	203(mm)	223(mm)	9.0
Intrusion at pelvis	191(mm)	208(mm)	8.2
Velocity at Chest	9.1(m/s)	11.0(m/s)	17
Velocity at Abdomen	8.9(m/s)	9.9(m/s)	10
Velocity at pelvis	8.6(m/s)	9.0(m/s)	4.4

For validating the stability of LPM, the intrusive velocity and displacement of chest, abdomen and pelvis in dummy at the condition of MDB initial velocity is 30km/h were exported. The comparison between LPM and FE was as shown in Figure.7.

(a)Chest (b) Abdomen (c) Pelvis

Figure.7 Comparison of intrusive velocities between LPM and FE at 30km/h

Optimization

In the earlier stage of new car development based on same platform, the target of vehicle safety performance should be disintegrated into a series of subsystem targets. The intrusive velocity and displacement of chest, abdomen and pelvis in dummy are always used for assessing the side impact performance [7]. In order to utilize the potential of side structure sufficiently, the stiffness of BIW was optimized by above LPM. The mathematical model of optimization was illustrated in follow formula:

$$\begin{aligned} &\text{Minimize} && U = f\left(x_1, x_2, \ldots x_k\right) \\ &\text{Subject to} && g_i\left(x_1, x_2, \cdots, x_k\right) = 0 \left(i = 1,2, \cdots, m\right) \\ & && h_j\left(x_1, x_2, \cdots, x_k\right) \le 0 \left(j = 1,2, \cdots, n\right) \\ & && x_1, x_2, \ldots x_k \in R \end{aligned} \tag{1}$$

Where U represents the objective function, $g_i\left(x_1, x_2, \cdots, x_k\right)$ represents the equation restrain, $h_j\left(x_1, x_2, \cdots, x_k\right)$ represents the non-equation restrain, $x_1, x_2, \cdots x_k$ represent the design variables.

The yield force scales of Front door, Rear door, B pillar and Rocker were defined as design variables as shown in Table 4, the intrusive velocity and displacement of chest, abdomen and pelvis in dummy were defined as design targets. A comprehensive assessment was defined about dummy injury in follow formula:

$$U=\left(\frac{V_{c1}-V_{c0}}{V_{c\max}-V_{c\min}}\right)^2+\left(\frac{V_{a1}-V_{a0}}{V_{a\max}-V_{a\min}}\right)^2+\left(\frac{V_{p1}-V_{p0}}{V_{p\max}-V_{p\min}}\right)^2+\left(\frac{D_{c1}-D_{c0}}{D_{c\max}-D_{c\min}}\right)^2+\left(\frac{D_{a1}-D_{a0}}{D_{a\max}-D_{a\min}}\right)^2+\left(\frac{D_{p1}-D_{p0}}{D_{p\max}-D_{p\min}}\right)^2 \quad (2)$$

Where $V_{c1}, V_{a1}, V_{p1}, D_{c1}, D_{a1}, D_{p1}$ represent the velocity of chest, abdomen, pelvis and intrusive displacement of chest, abdomen, pelvis respectively. $V_{c0}, V_{a0}, V_{p0}, D_{c0}, D_{a0}, D_{p0}$ represent the design target based on five star standard. $V_{c\max}$ and $V_{c\min}$ represent the max and min velocity of chest in sample points, so as $V_{a\max}, V_{a\min}, V_{p\max}, V_{p\min}, D_{c\max}, D_{c\min}, D_{a\max}, D_{a\min}, D_{p\max}, D_{p\min}$.

TABLE 4 UPPER, LOWER AND OPTIMUM OF VARIABLES UNIT (MM)

Variables	Lower	Initial	Upper	Optimum
Yield force scales of B pillar c_1	0.5	1.0	2.0	1.8722
Yield force scales of Front door c_2	0.5	1.0	2.0	1.4847
Yield force scales of Rear door c_3	0.5	1.0	2.0	1.2723
Yield force scales of Rocker c_4	0.5	1.0	2.0	1.1134

For solving this optimization problem rapidly, One hundred points were created by Latin Hypercube for establishing quadratic order RSM (Response Surface Model) which was validated by error analysis with thirty-three points. The stiffness of BIW was optimized by NLPQL (Sequential Quadratic Programming).The error coefficients R^2 of RSM were shown in table 5. It is indicated that the accuracy of approximate model was good because all error coefficients were exceeded 0.9.

TABLE 5 ERROR COEFFICIENT R^2 OF RSM

Objective function	R^2
Intrusion at Chest	0.92513
Intrusion at Abdomen	0.93455
Intrusion at pelvis	0.95951
Velocity at Chest	0.99823
Velocity at Abdomen	0.99825
Velocity at pelvis	0.99866

The target function based on RSM was optimized by NLPQL though 52 times iteration, the history of iteration was shown in Figure.8. The comparison of optimum results between LPM and approximate model was as shown in Table 6. The relative errors were not exceeded 1% and the performance improved 20%. The results indicated that the intrusive velocity and displacement of chest, abdomen and pelvis in dummy can be optimized by designing stiffness of BIW appropriately.

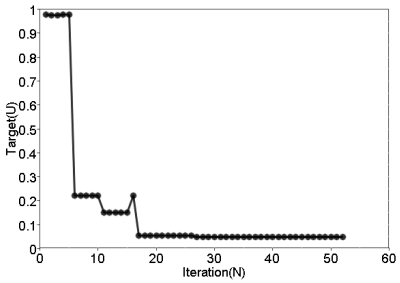


Figure.8 History of iteration

TABLE 6 RESULTS OF OPTIMIZATION

Objective function	Initial value	Optimum of RSM	Optimum of LPM	Relative error (%)	Improvement (%)
Intrusion at Chest	232mm	155.2 mm	155.95 mm	0.48	32.8
Intrusion at Abdomen	227mm	151.47 mm	152.21 mm	0.49	32.9
Intrusion at pelvis	215mm	143.1 mm	143.81 mm	0.49	33.1
Velocity at Chest	9.7m/s	7.4861 m/s	7.5027 m/s	0.22	22.7
Velocity at Abdomen	9.4 m/s	7.2761 m/s	7.2914 m/s	0.21	22.4
Velocity at pelvis	9.1 m/s	7.0981 m/s	7.1101 m/s	0.17	21.9

Conclusion

A rapid forward development strategy was proposed which used new type side impact LPM in new car based on same platform forward development. The example indicated that the intrusive velocity and displacement if chest, abdomen and in dummy can be optimized by designing stiffness of BIW reasonably. The development period can be shortened effectively by this method in new car development early stage. How to realize the stiffness of BIW in detail side structure CAD design stage is the next work.

Keywords: Dynamic Bayesian;Sea-battlefield;situation assessment

Abstract. How to efficiently evaluate the dynamic and complex the sea-battlefield situation facing the reality of the problem is the operational decision support. According to research sea-battlefield situation assessment based on improved dynamic Bayesian networks. First constructed the sea-battlefield situation assessment Bayesian networks model; second specific assessment task to establish the corresponding dynamic Bayesian networks; again reintroduced extended hidden variables, supplemental situation information to construct improved dynamic Bayesian networks; finally, according to the battlefield event reasoning, complete sea-battlefield situation assessment.

Introduction

Sea-battlefield is a giant complex system. The sea-battlefield situation assessment, both deterministic analysis of current events, or predictions of future events have the distinctive temporality, the time factor must be used as the assessment of the key factors. Dynamic Bayesian networks expansion the timing process modeling Bayesian networks, a collection of random variables can be evolved over time is compressed representation of a complex random processes. Quantitative assessment using dynamic Bayesian networks processing, give full consideration to the impact of timing factors, and the first time situational factors as current time situation assessment part of the evidence, and to predict the trend for the next time; at the same time can show continuity and cumulative characterization of the threat assessment. Therefore, based on the analysis of the characteristics of the sea-battlefield situation, the dynamic Bayesian networks applied to the complex sea-battlefield the sea-battlefield situation assessment reasoning.

Improved Dynamic Bayesian Networks Theory Overview Dynamic Bayesian Networks

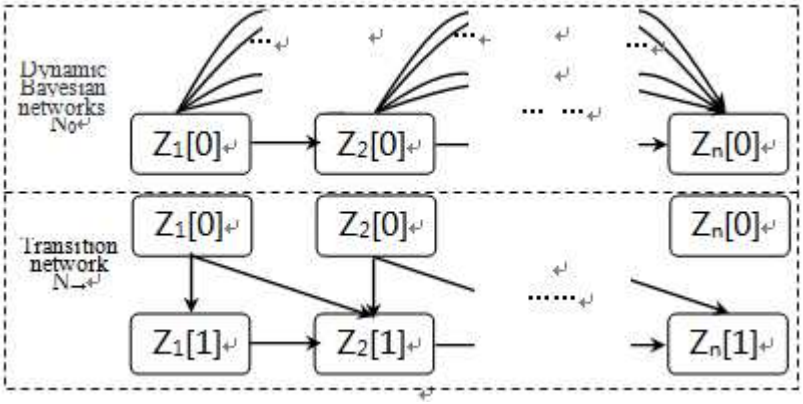

Fig.1 Dynamic Bayesian Networks

Dynamic Bayesian networks processing direction of the time factor on Bayesian networks extends as a knowledge representation and probabilistic reasoning framework. Assuming there is a Bayesian network, a set of variables for the discrete variables set $Z=(Z_1, Z_2, ..., Z_n)$, the set of variables Z sort

network topology, Z[t] for the variable set value of Z in the time t, Z_i[t] is a set of variables Z_i's value at time t. Dynamic Bayesian networks available Z[0]→ Z[1]→ ...→ Z[n] to represent the timing problem. Obvious need to deal with the dynamic Bayesian networks to get all the variables set Z[0] ∪ Z[1] ∪ ... ∪ Z[n], the set of conditional probability, in fact, such conditional probability of solving very difficult, and can cause quite high network inference complexity. In order to simplify the network, usually require dynamic Bayesian networks follows the Markov and time invariance assumption. A dynamic Bayesian network can be of two parts, part of the initial state contains a set of variables Z[0] Bayesian network N_0, another part is set by the variable Z[0] and Z[1] constitute, and give $P_{N\rightarrow}$ (Z[t +1] | Z[t]) the probability distribution of the transition condition of the transition network $N_{\rightarrow}$ two parts, the specific composition is shown in Fig. 1.Therefore, a dynamic Bayesian networks by tuple: DN = <N_0, $N_{\rightarrow}$>., the probability of transition condition of $N_{\rightarrow}$ can be written as Eq. 1:

$$P_{N\rightarrow}(Z[t+1]/Z[t]) = \prod_{0}^{n} P_{N\rightarrow}(Z_i[t+1]/PaZ_i[t+1]) \quad (1)$$

The joint probability of the entire set of variables as Eq. 2:

$$P(Z[0],Z[1],\cdots,Z[T]) = P(Z[0])\prod_{t=0}^{T-1} P_{N\rightarrow}(Z[t+1]/Z[t]) \quad (2)$$

The Introduction of the Extended Hidden Variables

Dynamic Bayesian networks hidden variables introduced the original intention to make the original dynamic Bayesian networks model with Markov properties. On this basis, we can propose the extension of hidden variables. That does not meet the local network, such as a random variable probability distribution specified state or a specified value, do not participate in the probability of network nodes update calculation; when the local probability distribution of the designated state or a specified value, the impact on the global probability distribution of the network, the random variable can be referred to as the expansion of hidden variables.

Be seen from the above analysis, the introduction of dynamic Bayesian networks expansion hidden variables, not only can add some status information to the original dynamic Bayesian networks model, transferred to the additional variable makes the subsequent time slice on the variable dependencies; but also qualitative dependence between the number of makes random variable and can be set and random variable having characteristics change over time. But the introduction of the extended hidden variables Bayesian networks model must first be guaranteed Markov and time invariance assumption. From the literature [2] to prove that the introduction of hidden variables improved dynamic Bayesian networks model is always equal to 4, and therefore not increase the complexity of the original model, improved dynamic Bayesian networks model satisfies the Markov and time invariance assumptions.

The Sea-battlefield Situation Improved Dynamic Bayesian Assessment Model

The sea-battlefield situation assessment application of dynamic Bayesian networks for solving the problem solving process can be divided into three steps; first is to establish the sea-battlefield situation assessment model Bayesian network structure; second is built on the basis of the improved dynamic Bayesian network; finally, based on the evidence obtained information Bayesian networks inference drawn sea-battlefield situation assessment conclusions.

Design Sea-battlefield Situation Assessment Bayesian Networks Structure

Here we have chosen a relatively simple surface ship fleet antiaircraft defense scenario, said sea-battlefield situation assessment of dynamic Bayesian model design, building and reasoning. Specific combat situation is set to: the war environment Open ocean area, Climatic conditions to meet the opposing sides weapons use requirements; in our fleet of surface ships, equipped with SAM(ship to air missiles), electronic countermeasures and radar and other systems; the enemy for the Air Force

fleet, equipped with ASM(air-ship missiles), electronic warfare and radar systems; the enemy tactics intentions for the search to find and assault my surface ships fleet; our tactical intent to carry out the fleet antiaircraft defense operations; the purpose of our sea-battlefield situation assessment is to ensure that our greatest degree seize the control initiative on the battlefield; that infer the enemy's tactics may be used according to the current trend factors we take the most effective measures accordingly.

Surface ship fleet antiaircraft scenarios mainly consider the following three situational factors:

1) Visible distance, i.e., the relative distance between two sides of visible, set two critical distance, assault weapons effective range and detection system effective distance. The value of the Outside (> Max (detection system effective distance & assault weapons effective range)); In(Max (detection system effective distance & assault weapons effective range) ≥ visible distance ≥ Min (detection system effective distance & assault weapons effective range)); Within (<Min (detection system effective distance & assault weapons effective range)).

2) Fighting determination, that the two sides of the implementation of a fighting attitude, value Positive (before finding the target; Finding the target and proactively identify; Confirm the target and attack);General (maintain existing athletic stance);Negative (keep a safe distance from the target, or do not take the initiative to attack).

3)Target identification, that the two sides of assault or incoming targets to identify possible, value is Clear (after finding the target can quickly distinguish the target type);Normal (determine target type target after a period of time);Fuzzy (finding the target, the target type can not be determined).

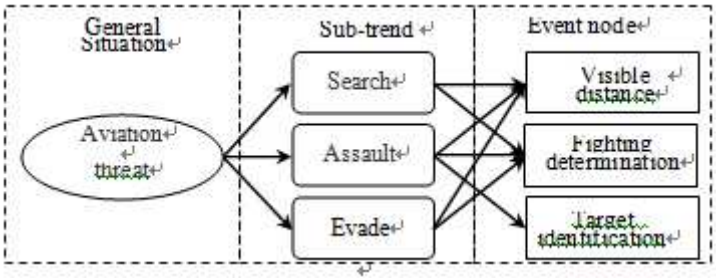

Fig.2 Bayesian Networks Structure Diagram

Select the aviation threat for both sides against the total momentum, which contains three sub-trend; Search, Assault and Evade. Which sub-trend "Search", "Visible distance" and "Fighting determination" associated; Sub-trend "Assault", "Visible distance", "Fighting determination "and "target identification" associated; Sub-trend "Evade", "Visible distance"and "Fighting determination" associated. Based on the above analysis, the sea-battlefield surface ship fleet antiaircraft posture to assess Bayesian networks structure as shown in Fig.2.

Building Sea-battlefield Situation Assessment Model Based on Improved Dynamic Bayesian Networks

Sea-battlefield surface ship antiaircraft operations is obvious dynamic complex process involving the warring parties countermeasures. Each event occurred in the sea-battlefield exists to some extent associated with events that occurred before, and that is the first time the sea-battlefield situation will inevitably impact on sea-battlefield situation to a certain extent on the current moment, and therefore can not ignore the situation assessment time factor. Based on the above analysis, we can building improved dynamic Bayesian networks inference and prediction of sea-battlefield situation any time.

According to the theoretical analysis of Section II, the sea-battlefield surface ship fleet antiaircraft defense posture assessment Bayesian networks N_0 dynamic Bayesian networks model is also by situational factors variable contains the initial state set Z[0] set of variables and situational factors Z[0] and Z[1] constitute the given transition conditional probability distribution $P_{N\rightarrow}(Z[t+1] \mid Z[t])$ of the transition network $N_{\rightarrow}$ two-part, and to follow the Markov and time invariance two assumptions.

Sea-battlefield surface ship antiaircraft defense posture assessment improved dynamic Bayesian networks model complex electromagnetic environment factors introduce extensions hidden variables

sea-battlefield. Introduction of the extended hidden variables, not only for the antiaircraft defense posture assessment supplemental the electromagnetic environmental impact related information, but also enable the antiaircraft defense posture review random variable set of qualitative dependencies between size and variable changes over time, and can guarantee that the dynamic Bayesian networks model satisfies the Markov and time invariance assumption. Extended hidden variables the sea-battlefield complicated electromagnetic environment factors set two key threshold. Guided blocking threshold (I): the sea-battlefield electromagnetic strength of the values of the indicators, lapsed assault weapons guidance systems. The search mask threshold value (II): sea-battlefield electromagnetic strength of the values of the indicators, early warning search system failure.

When the sea-battlefield electromagnetic strength threshold is reached, the expansion of hidden variables (sea-battlefield complex electromagnetic environment factors) involved in antiaircraft defense posture to assess the probability of dynamic Bayesian networks model node update calculation; hen the local probability distribution reach guided blocking threshold value (I) or search mask threshold (II), is involved in target identification model node probability update affect antiaircraft defense posture to assess the probability distribution of dynamic Bayesian networks globally.

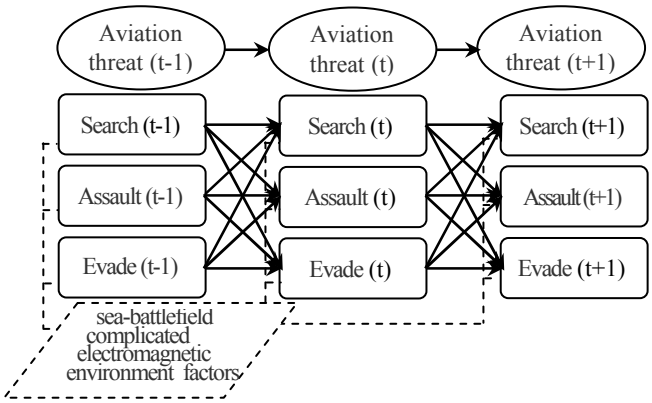

Fig.3 Improved Dynamic Bayesian Networks.

Based on the above analysis, three time slices (the current time slice t, the previous time slice t- and the next time slice t+1), for example, the sea-battlefield surface ship fleet antiaircraft defense posture assessment improved dynamic Bayesian networks model specific configuration shown in Fig.3.

Bayesian Networks Inference Sea-battlefield Situation Assessment

The sea-battlefield surface ship fleet antiaircraft defense posture assessment improved dynamic Bayesian networks model to introduce the extended hidden variables sea-battlefield complicated electromagnetic environment factors dynamic Bayesian networks. Its reasoning process of the first combination of the use of literature [2], the EM algorithm and Bayesian statistics BDE scoring function, cyclical iterative learning dynamic Bayesian networks structure with extended hidden variables, can draw on expertise, given the probability distribution of all the random variables in all the time slice may solve the local optimum problem that may arise; commonly used algorithm of junction tree algorithm, or cut-set conditional methods such as Bayesian network can then use to complete the reasoning.

Sea-battlefield Situation Assessment Example Analysis

Such as t=0 and t=1 time slice of the the sea-battlefield situation factors such as probability distribution data in Table 1 shown below.

TABLE 1 SEA-BATTLEFIELD SITUATIONAL FACTORS PROBABILITY DISTRIBUTION TABLE

Time slice	Visible distance			Fighting determination			Target identification		
	Outside	in	Within	Positive	General	Negative	Clear	Normal	Fuzzy
t=0	0.63	0.22	0.15	0.52	0.25	0.23	0.71	0.15	0.14
t=1	0.28	0.51	0.21	0.61	0.28	0.11	0.75	0.13	0.12

Based on reasoning algorithm, we can obtain t=1 time slice of antiaircraft defense posture, and forecast t=2 time slice of antiaircraft defense posture, specific assessment values in Table 2 below.

TABLE 2 SEA-BATTLEFIELD SITUATION ASSESSMENT TABLE OF VALUES

Time slice	Extended hidden variables	Aviation threat		Assault		Search		Evade	
		True	False	True	False	True	False	True	False
t=1	<Threshold Ⅰ & Ⅱ	0.43	0.57	0.16	0.84	0.76	0.24	0.28	0.72
t=2	<Threshold Ⅰ & Ⅱ	0.69	0.31	0.63	0.37	0.32	0.68	0.13	0.87
	≥Threshold Ⅰ	0.16	0.84	0.42	0.58	0.53	0.47	0.45	0.55
	≥Threshold Ⅱ	0.13	0.87	0.11	0.89	0.41	0.59	0.78	0.22

Analysis improved dynamic Bayesian networks model to assess value available, When t=1 time slice visible distance, the fighting determination is positive, target recognition is clear, judgment at this time uncertain the sea-battlefield surface ship antiaircraft defense posture aviation threat, weak trend in the aviation threat (False distribution probability close to the set threshold value of 65%).

And when t=2 time piece extensions hidden variables sea-battlefield complicated electromagnetic environment factors local probability distribution is not reached guided blocking threshold value (I)or search shielding threshold (II), predicted sea-battlefield water surface warship fleet antiaircraft defense posture of the aviation threat (True distribution probability reaches a set threshold value). Air Force fleet carries out assaults, can achieve effective search and target identification is clear and visible distance continues to decrease, Air Force fleet constantly close to the attack position threat has continued to improve.

When t=2 time piece extensions hidden variables sea-battlefield complicated electromagnetic environment factors local probability distribution to achieve guided blocking threshold value(I), predicted sea-battlefield water surface warship fleet antiaircraft defense posture of the aviation threat weak (False distribution of the probability of exceeding set threshold), Air Force fleet action status is unknown, can achieve effective search, visible distance continues to decrease, the Air Force is constantly approaching surface ship fleet, but the guidance system failure can not be reached surprise necessary condition Threat Reduction.

When t=2 time piece extensions hidden variables sea-battlefield complicated electromagnetic environment factors local probability distribution reach search shielding threshold (II), predicted sea-battlefield water surface warship fleet antiaircraft defense posture of the aviation threat to the weak (False distribution of the probability of exceeding set threshold) and Air Force fleet carry out evasive action, unable to achieve an effective search, resulting in reduced threat.

Reasoning improved dynamic Bayesian networks model to assess sea-battlefield situation can be seen conclusions credible. Predict more complex situation is not ideal, to analyze the main reason is built the sea-battlefield situation assessment model included the representation of the potential link between the amount of information and the factors of the situational factors is not comprehensive, need to be further improved.

Summary

The sea-battlefield situation assessment application improved dynamic Bayesian networks. First can use dynamic Bayesian time series modeling of complex stochastic process scalability to address the problem of the sea-battlefield situation assessment of the impact of the time factor; then by

introducing the extended hidden variables, rich battlefield situation assessment information to solve a large number of sea-battlefield situational factors not fully recognize the description of the potential relationship and deep impact assessment. Future research will also continue to explore the dynamic Bayesian networks structure optimization, in order to improve the efficiency of the operations of the sea-battlefield situation assessment.

Keywords: Fuzzy Control Strategy, Particle Swarm Optimization(PSO), Hybrid Electrical Vehicle (HEV), Energy Control.

Abstract: Energy control of HEV plays a very important role in the process of HEV design, which is directly related to the safety and feasibility. Considering the drive system of HEV is nonlinear and complex, a fuzzy control strategy which is combined with particle swarm optimization algorithm is designed to realize the energy control of HEV. Fuzzy control strategy does not need to built accuracy mathematics model and has good robustness, but it mostly depends on engineering experience and has poor ability of self-learning. So particle swarm optimization algorithm has been added to solve these disadvantages of fuzzy control strategy. In conclusion, this method can not only keep the advantage of fuzzy control strategy, but also has ability of self-learning and self-adapt because of particle swarm optimization added. And the simulation proves that this method is feasible and effective.

Introduction

In recent years, the price of oil keep increasing all over the world, the global problem of energy is more and more obvious. As an important part of oil consumption, Automobiles begin to seek for technical innovation. Hybrid electrical vehicle (HEV) and electric vehicle (EV) are emerged under this circumstance.

Energy control of HEV plays a very important role in the process of HEV design. Only appropriate distribution of energy can realize the real value of HEV. At present, the energy strategy of PHEV mainly are steady control strategy based on rules, fuzzy control strategy, instantaneous optimization control strategy, global optimization control strategy[1].

In this article, an energy control strategy which is based on fuzzy control strategy combined with particle swarm optimization(PSO) has been designed aiming at parallel hybrid electric vehicle (PHEV). Simulation proves that it has good actual results.

Structure of Parallel Hybrid Electric Vehicle

Parallel hybrid electric vehicle is mainly composed of engine, battery and generator/motor. The engine and motor are non-coaxial, so the engine and motor can drive cars separately[2], its structure is as follow:

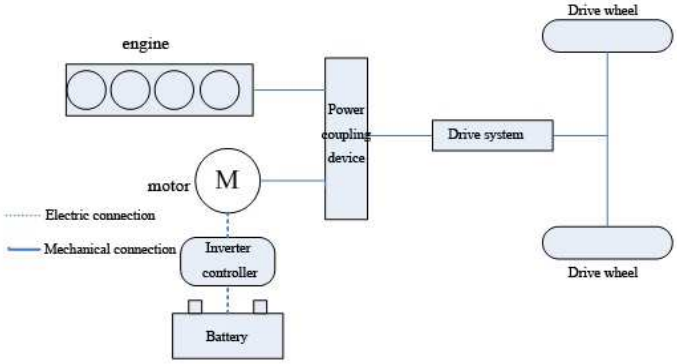

Fig. 1 Structure of PHEV

During the running of PHEV, engine drives gearbox to drive the car, at the same time, the electric drive system can also drive the car through the battery and motor, the power is overlying. When the car is running steadily, it is mainly driven by engine. If the battery power is low, engine can give more power to charge the battery which is based on the engine is working at the optimal state. When the car demands large torque such as quick acceleration or uphill, electric drive system can assist the engine to provide the large torque to ensure the dynamic property of PHEV.

Since the power of two drive systems can be overlaid, it can use the engine and motor of smaller power which can make the power assembly small, light and low cost. But in parallel hybrid electric vehicle, engine is impacted by driving condition, so it is not suitable to the driving condition which varies frequently.

Control Strategy of PHEV

In order to achieve the fuel economy, cancel the idle speed state of the engine and the starting state that the efficiency of the engine is very low. The normal running of the vehicle is mainly driven by engine. If the demand torque is less than the optimal torque of the engine under current speed, redundant torque is used to charge the battery. If the demand torque is more than the optimal torque under current speed, motor is used to provide the insufficient torque so as to keep the engine working under the best working condition[3]. That means to keep the engine always working under the best working condition.

This paper aims to make the reasonable distribution of the demand torque under normal running process. So choose the demand torque of the running process T_{req} as one of the inputs of the fuzzy controller. Because the SOC of the battery must always be known during the running process, choose SOC of the battery as the other input of the fuzzy controller. Then the output of the fuzzy controller is the output torque of the engine T_e the output torque of the motor T_m can be calculated by $T_m = T_{req} - T_e$ (assuming that the torque coupler ratio is 1). In order to ensure the generality of the fuzzy controller, use the following formula to do the field transformation of demand torque T_{req} which can change the actual physical quantity to real number between -1 and 1.

$$\begin{cases} \dfrac{\Delta T}{T_{e_\max} - T_{e_opt}} & \Delta T \geq 0 \\ \dfrac{\Delta T}{T_{e_opt}} & \Delta T \leq 0 \end{cases} \tag{1}$$

Where $T_{e_\max}$ is the maximum torque of the engine, T_{e_opt} is the optimal torque of the engine under current speed, $\Delta T = T_{req} - T_{e_opt}$ is the difference between the demand torque and the optimal torque of the engine[4].

In conclusion, the picture of the structure of the fuzzy controller is as follow.

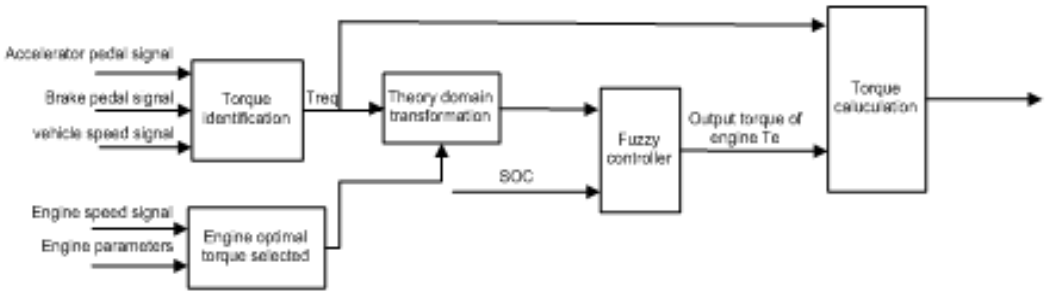

Fig.2 Structure of fuzzy controller

The design of membership functions of input and output of the fuzzy controller is as follow:

Demand torque $T_{req}^{'}$ is divided into $\{MN, N, ZERO, P, MP\}$, theory field is [-1,1]. The SOC of battery is divided into $\{lower, low, opt, high, higher\}$, theory field is [0.4,0.8]. Output torque of the engine T_e is divided into $\{smaller, small, opt, big, bigger\}$, theory field is [0,1]. The forms of membership functions are all trimf combined with trapmf.

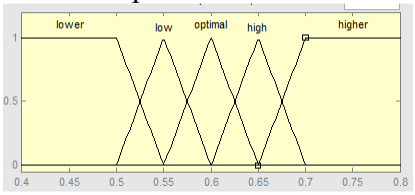

Fig.3 SOC MF

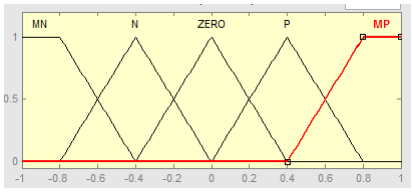

Fig.4 Demand torque MF

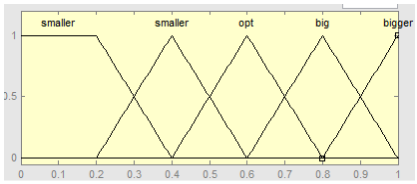

Fig.5 Output torque of engine MF

Fuzzy control rules are as follow：

TABLE3-1 FUZZY CONTROL RULE TABLE

T_e		SOC				
		lower	low	opt	high	higher
$T_{req}^{'}$	MN	opt	opt	smaller	smaller	smaller
	N	big	opt	small	small	Small
	ZERO	Bigger	Big	Opt	Opt	Opt
	P	Bigger	bigger	Big	Big	Opt
	MP	bigger	bigger	bigger	big	big

Basic particle swarm optimization algorithm (PSO) is a new random global optimization algorithm. For a n-dimensional search space, particle is represented as $X=\{x_1, x_2, \cdots, x_m\}$, each particle is a feasible solution in the search space which is going to be optimized. Each particle seeks for optimal solution through cooperation and competition[5]. The position of the i^{th} particle is represented as $x_i=\{x_{i1}, x_{i2}, \cdots, x_{in}\}^T$, the speed of the particle is represented as $v_i=\{v_{i1}, v_{i2}, \cdots, v_{in}\}^T$, individual extremum is represented as $p_i=\{p_{i1}, p_{i2}, \cdots, p_{in}\}^T$, global extremum is represented as $p_g=\{p_{g1}, p_{g2}, \cdots, p_{gn}\}^T$, the speed and position update according to the follow formulas:

$$v_{id}^{k+1}=\omega v_{id}^{k}+c_1\times rand()\times\left(p_{id}-x_{id}^{k}\right)+c_2\times rand()\times\left(p_{gd}-x_{id}^{k}\right) \tag{2}$$

$$x_{id}^{k+1}=x_{id}^{k}+v_{id}^{k+1} \tag{3}$$

Where $i=1,2,\cdots,m$, m is the total number of the particle. K is the current iterations. v_{id}^{k} is the d^{th} weight of the velocity vector of the k^{th} generation particle i. p_{id} is the d^{th} weight of individual optimal position value $pbest$ of current particle i. p_{gd} is the the d^{th} weight of global optimal position value $gbest$ of current swarm. ω is the inertial weight. c_1 and c_2 are the acceleration constants. $rand()$ is random numbers between 0 and 1[6].

Now use variables x_1,x_2,y_1,y_2,z_1,z_2 to encode membership functions as follow:

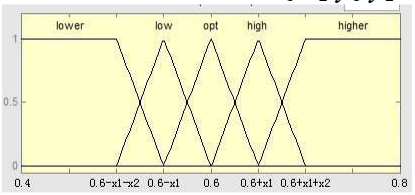

Fig.6 Encoding SOC MF

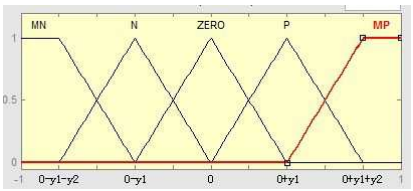

Fig.7 Encoding demand torque MF

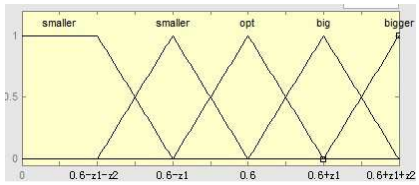

Fig.8 Encoding output torque of the engine MF

In order to make fuel consumption minimum, use PSO algorithm to optimize the fuzzy controller, the algorithm flow chart is as follow[7].

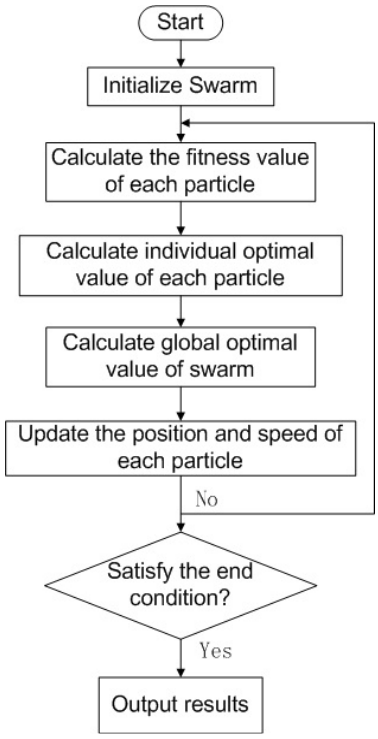

Fig.9 Algorithm flow chart of PSO

Simulation

A forward simulation model has been built on MATLAB/Simulink, it includes diver model, engine model, motor model and vehicle model. Then program in the S-function to realize the simulation. The results of the simulation are as follow.

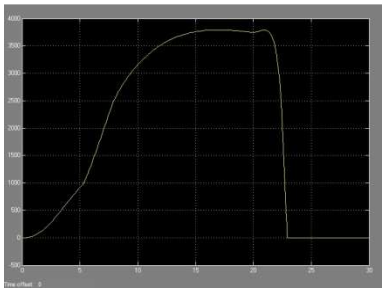

Fig.10 Speed of vehicle

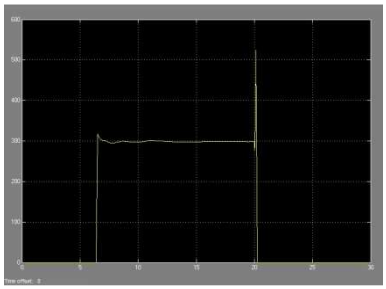

Fig.11 Fuel consumption

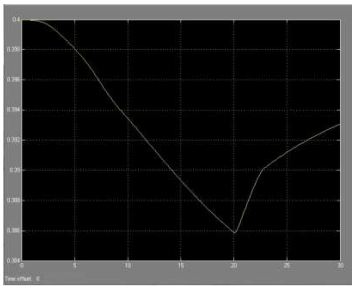

Fig.12 SOC

Figure 10 is the speed of the vehicle, the model simulates a working condition that includes states of starting, accelerating quickly, accelerating slowly, slow down and parking. These states can be recognized from figure 10. Figure 11 is the fuel consumption of the vehicle which is corresponding to these states. From figure 11, it can be tell that the fuel consumption of starting state is zero, which means the fuel consumption of the lowest efficient state is zero. And during the whole accelerating state, the fuel consumption is almost constant, which means the motor works in that state to keep the engine work under higher efficient state, which can also make the fuel consumption less. Also from figure 12, SOC of battery decreases during the accelerating state, so the motor must work to offer some torque which can not only meet the demand of running, but also keep the engine work under higher efficient state. When the car slows down, it entry into regenerative braking state to charge the battery.

From the results, it can be see that idle speed state and the starting state are cancelled, which means motor takes over the lowest efficient states of engine. And with the assist of motor, engine can work under efficient state. From the figure 12, it can be see that regenerative braking state is realized. And during the whole working condition, the SOC of battery does change too much, and the battery is only charged once which can keep the battery a long life.

Summary

In this paper, a fuzzy control strategy based on particle swarm optimization has been designed in order to solve the problem of energy control of HEV. This method designs a fuzzy controller according to the running process of HEV which the inputs are SOC of battery and the demand torque and the output is the output torque of engine. Then use PSO algorithm to optimize the membership functions of inputs and output of the fuzzy controller so as to make the fuel consumption minimum. This method combines the advantages of fuzzy control and particle swarm optimization, has good robustness and precision.

Keywords: Non-Ideal behavior, Energy Harvesting, Random Vibration, Efficiency.

Abstract: Common solution for energy harvester device is project design according harmonic excitation around natural frequency matching excitation source. Environment vibration is random and wide band causing short time of resonance in disagreement of project objectives. Control driven of energy harvesting to take advantage of the higher vibration range can results in greater energy converted. This study investigates a non-ideal excitation behavior and their efficiency in convert electricity via piezoelectric direct effect from the available system energy compared to harmonic excitation source. Numeric evaluation was performed based in bimorph piezoelectric beam in dimensionless consideration. Chaos behavior and harvest energy capability were compared from non-ideal to harmonic excitation. Results demonstrate considerable higher quantity of energy available for non-ideal approach compared to harmonic resonant design and encourages advance study to control and enhance energy from random and wide band vibration source.

Introduction

Energy Harvesting is harnessing energy from the environment. The most common sources of environmental energy for harvesting systems are solar, thermal gradients and mechanical and acoustic vibrations [1].

Vibrational energy harvesting technique is considered attractive for low-power devices, for example, wireless sensor [2]. The vibration energy to be harnessed can be from structures motion and acoustic waves [3], for example. The vibration energy can be converted into electrical energy by means of piezoelectric materials, electromagnetic and electrostatic transducers. Using harvesters as power source a device can be in operation for long periods or even indefinitely, without need of any other power source or an energy storage system [4].

Harmonic excitation for energy harvesting investigation normally considers natural frequency for resonance response [5]. It is notable in piezoelectric harvesters devices a vibration amplification when natural frequency matches vibration frequency source. However, the environment offers a wide range of vibration and such project solution is not taken advantage of the broadband [6]. In this direction some solution were proposed, for example bi-stable magnetic cantilever, which can absorb more energy from the system [7]. These designs are known as non-linear solution. Among linear and non-linear approach a harmonic excitation was considered as power source [8]. Nevertheless environment vibration can be considered as a non-ideal power source and cannot be modeled as a harmonic excitation which has constant amplitude and frequency.

According [9], when an excitation is not influenced by system response it is considered an ideal excitation that has origin in an ideal energy source. On the other hand, when the excitation is influenced by the system response the excitation is considered to be non-ideal. Since, non-ideal system presents an equation that describes the interaction between power source and the dynamic system. Therefore, in non-ideal system the dynamics depends directly on excitation properties whose

available energy power, generally, it is limited. The main propose of this study is to investigate a non-ideal behavior of a piezoelectric bimorph cantilever used for energy harvesting. There will be a comparison of energy offered from a harmonic and non-ideal vibrating excitation as power source. The study takes in consideration numeric evaluation.

Considering the paper organization: section 2 presents the harmonic and non-ideal modeling approach. Section 3 presents the evaluation results comparison considering harmonic and non-ideal excitations. Finally, section 4 presents the final remarks from this investigation and acknowledgements.

Harmonic and Non-Ideal Approach

A bimorph cantilever excited by a harmonic [7] or non-ideal vibration [9] is given in Fig. (1), including an electrical load circuit. Previous study performed in [7] compared performance of linear and non-linear approach; however the accomplished study only considered harmonic vibration as excitation source and this present study considers non-ideal excitation.

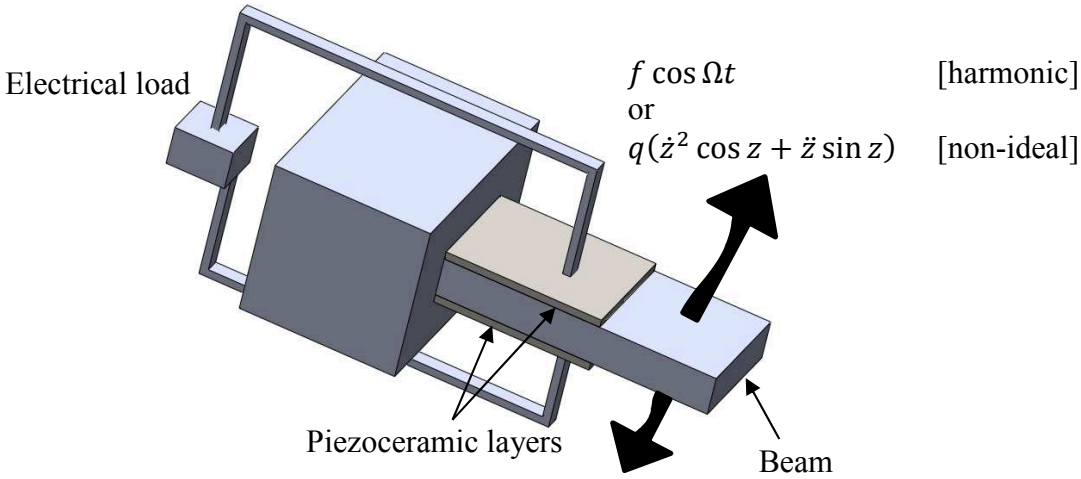

Fig. 1- Bimorph Cantilever [7].

Harmonic Model.

The dynamic model for the proposal energy harvesting subject to a harmonic excitation is given in dimensionless Eq. (1), where ζ is the damping, χ is piezoelectric mechanical coupling, v is the resistance voltage, f is force, Ω is the frequency, Λ is reciprocal of time constant and k is piezoelectric electric coupling. It is a dimensionless dynamic model proposed by [7].

$$\begin{aligned}\ddot{x}+2\zeta\dot{x}+x-\chi v&=f\cos\Omega t\\ \dot{v}+\Lambda v+k\dot{x}&=0\end{aligned} \tag{1}$$

The space-state form of Eq. (1) is given by Eq. (2):

$$\begin{aligned}\dot{x}_1&=x_2\\ \dot{x}_2&=-2\zeta x_2-x_1+\chi x_3+f\cos\Omega t\\ \dot{x}_3&=-\Lambda x_3-\kappa x_2\end{aligned} \tag{2}$$

Non-Ideal Model.

The coupled system excited by non-ideal vibration can be model according Eq. (3), where z is a non-ideal excitation response and the values (a, b, q, r) are positive dimensionless constants [9]. The same coupling presented by [7] is considered in non-ideal model and only the excitation source is replaced for this study. Is important to notice that non-ideal model do not consider resonance because power is limited and the vibration influence his own behavior as can be notice by the z component.

$$\ddot{x}+2\zeta\dot{x}+x-\chi v=q(\dot{z}^2\cos z+\ddot{z}\sin z) \tag{3}$$

$$\ddot{z} + b\dot{z} = r\ddot{x}\sin z + a$$
$$\dot{v} + \Lambda v + k\dot{x} = 0$$

The space-state form of Eq. (3) is given by Eq. (4):

$$\begin{aligned}
\dot{x}_1 &= x_2 \\
\dot{x}_2 &= \frac{-x_1 - 2\zeta x_2 + \chi x_5 + \mathrm{q}x_4{}^2\cos(x_3) + \mathrm{q}\sin(x_3).(\mathrm{a} - \mathrm{b}x_4)}{1 - \mathrm{qr}\sin^2(x_3)} \\
\dot{x}_3 &= x_4 \\
\dot{x}_4 &= \frac{\mathrm{r}\sin(x_3).(-x_1 - 2\zeta x_2 + \chi x_5 + \mathrm{q}x_4{}^2\cos(x_3)) + a - bx_4}{1 - \mathrm{qr}\sin^2(x_3)} \\
\dot{x}_5 &= -\Lambda x_5 - \kappa x_2
\end{aligned} \tag{4}$$

Performance Comparison Analysis

Analysis was performed according Runge-Kutta method for solving ordinary differential equations and the results and discussions are presented.

Harmonic Parameters.

For Harmonic excitation the dimensionless parameters are used according [7] given in Table 1. It is notable the frequency f = 0.083 matches the resonance natural frequency of the bimorph cantilever.

Table 1- Parameters for Harmonic Excitation.

Parameter	ζ	χ	f	Ω	Λ	κ
Value	0.01	0.05	0.083	0.8	0.05	0.5

Non-Ideal Parameters.

For Non-Ideal excitation the dimensionless parameters are used according [9] given in Table 2.

Table 2- Parameters for Non-Ideal Excitation.

Parameter	a	b	r	q
Value	2.3	1.5	0.5	0.5

Stability.

Lyapunov exponents were calculated by Wolf method [10] and can be notice according Fig. 2 that harmonic excitation has negative exponents resulting in stable comportment and the non-ideal excitation has a positive exponent causing chaotic behavior.

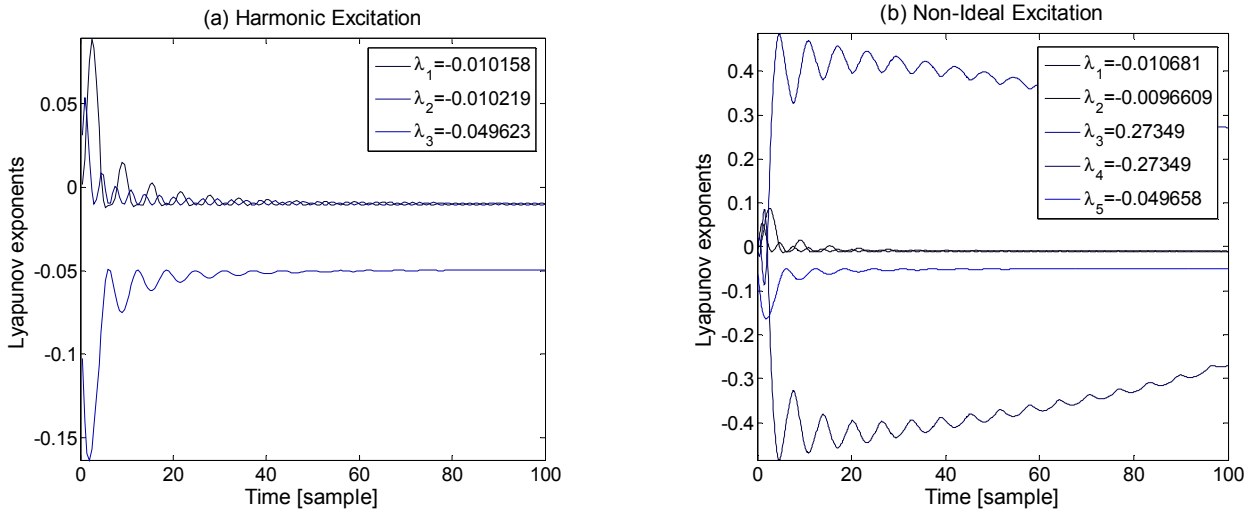

Fig. 2 - Lyapunov Exponents via Wolf method.

The Eigenvalues for harmonic excitation can be seen in Table 3.

Table 3 - Eigenvalues for harmonic excitation.

λ_1	-0.01061 + 1.01235i
λ_2	-0.01061 + 1.01235i
λ_3	-0.0488 + 0.0000i

Time History.

In order to compare harmonic and non-ideal it was computed displacement and velocity considering time history from 100 samples. For displacement time history (Fig. 3) and velocity time history (Fig. 4) it was possible to conclude that non-ideal excitation offers around seven times more amplitude. It can be note that harmonic excitation was chosen according resonance and then the amplitude should be greater from this model, however the non-ideal excitation instead not be aided for resonance effect, has the chaotic effect in his favor.

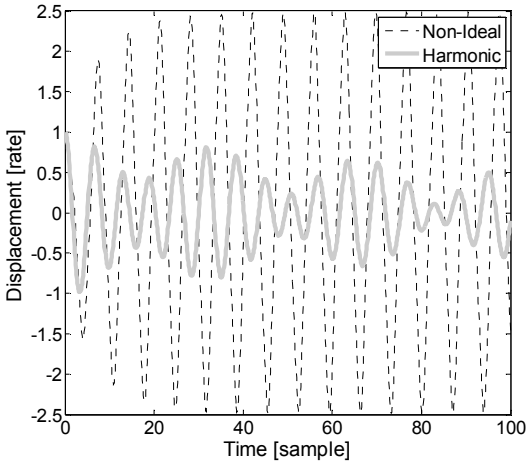

Fig. 3 - Displacement

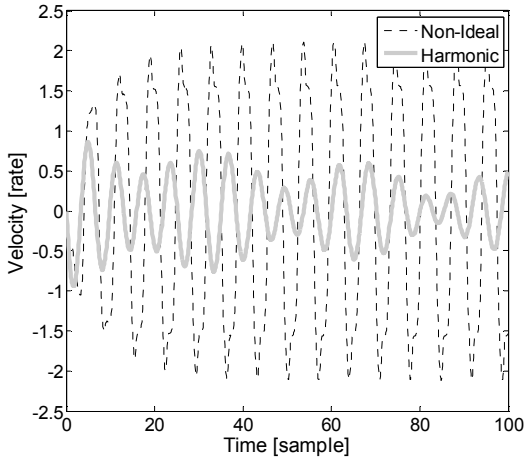

Fig. 4 - Velocity

Since displacement and velocity amplitude has direct relation to energy harvested, than non-ideal system presents a preferable behavior compared to harmonic excitation.

Phase Portrait.

A phase portrait of velocity x displacement (Fig. 5) demonstrates how many kinetic energy is available in the system. It is possible to verify that non-ideal excitation results in expressive more kinetic energy than harmonic excitation.

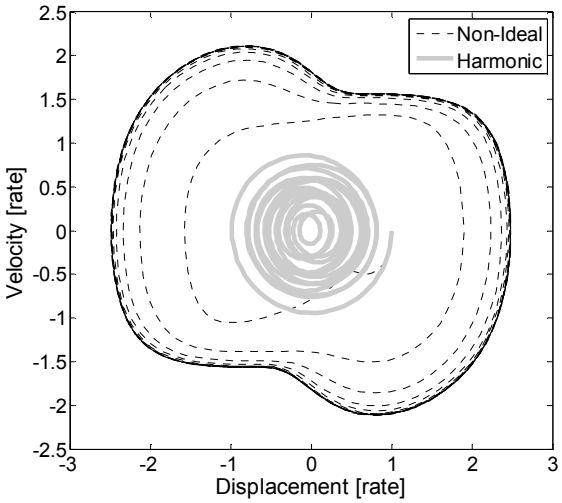

Fig. 5 - Velocity x Displacement

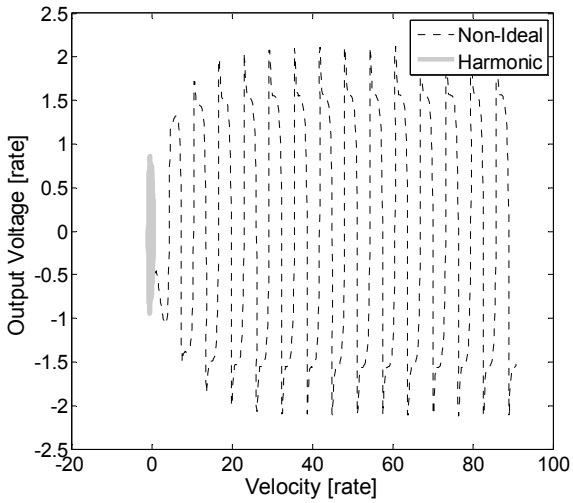

Fig. 6 - Output Voltage x Velocity

The total vibration energy that can be converted in electricity is presented by phase portrait of output voltage x velocity (Fig. 6). It can be seen that non-ideal excitation is more efficient considering

total energy absorbed from the system. Again it is important to emphasize that harmonic excitation match resonance and takes advantage of this condition. As environment vibration has a large range, than resonance will occur only in a certain period of time and non-ideal excitation could have an even more superior behavior.

Final Remarks

Many studies regarding energy harvesting has been outcome in the last few years. The principal propose from these many works is to enhance the harness capability from energy harvesters which conducted to dynamic analysis and project designs proposals. In the same direction, this investigation presented a study of dynamic behavior considering harmonic and non-ideal excitation.

As principal result it was possible to evaluate the promising superiority of non-ideal excitation in harnessing energy from environment. Such results encourage studies focusing in dynamic control to tuning harvesters to a non-ideal instead harmonic behavior.

Keywords: Fuzzy theory; water level controller; supercharged boiler; PID.

Abstract: Based on the application of the fuzzy theory,we designed a state level fuzzy controller for the marine steam power system. Compared with the level PID controller and a single-stage cascade PID level controller about disturbance response, the state level controller is more suitable for marine supercharged boiler level control because of its Smaller overshoot, shorter settling time, and other characteristics.

Introduction

Drum level is an important parameter affecting the safe operation of the boiler,for a lower or higher water level could cause a major accident, therefore, the study of boiler water level control is necessary. PID control is often used as level control method, which has intuitive, simple,good robustness characteristics,the premise of this method is to obtain a mathematical model , while the boiler is a complex objects ,which is nonlinear, multivariable adjustments, large lag and strong interference, and the presence of coupling of multiple variables, it is difficult to establish accurate mathematical model. So it is difficult to achieve the desired control effection just apply a PID control, and it is not ideal for the phenomenon of false water level in the drum level control [1]. To achieve good control effection, it needs to be improved on the basis of PID control.

Deriving fuzzy PID control strategy from the fuzzy PI was proposed by Om Prakash [2], Weeka Meshram et al made a further advance study [3] . AMProkhorenkov, ASSovlukov et al [4] used the fuzzy control strategy in centralized control system of the boiler .Compared with other control strategies rule ,the relative merits of the fuzzy controller is simply accessible, easy to implement, and a better control effection. Many scholars has made a contribution in fuzzy water level control . For example , to settle issues that the PID control parameters can not adapt to errors change , Chen Lin [5] et al make the error range according to the water level PID parameters in the actual operation of the process PID controller to form a cascade three impulse fuzzy PID control system.Huang Ming Zhang [6]adjusted PID control parameters by fuzzy controller , and compared results by controlling the simulation with PID controllers , and gave the method to achieve fuzzy control on hardware. Zhang Yongsheng [7] designed a humanoid combining logic level control strategy which was controlled by PID and fuzzy based on human logic features, the control method composed by PID and fuzzy control channel.

These studies focused on utility boiler drum level control, but less on marine supercharged boiler drum level control. Compared with power plants steam power systems, marine steam systems change conditions frequently in accordance with the requirements of the ship Operating conditions, the interference of the load to the drum level is uncertain,the changes of drum level have large non-linear , load disturbances, uncertain time lag and other features. In this paper, , a drum level fuzzy controller was designed for small marine boiler based on the research of utility boilers.

Designing Fuzzy Controller

Fuzzy controller is the core part of fuzzy control, the design steps of Fuzzy controller is Divided into determining the structure,definiting fuzzy sets, determining the membership function, building fuzzy control rules, and anti-blur.

Building Fuzzy Relationship

In this paper, the fuzzy controller selects two-dimensional structure,the water level errors and water level error changes will be used as input variables,and the control variables (valve) is output. As the state balance point,the valve position Selects 19.02, the steam flow is 0.187kg /s.

According to the demand for automatic control of the experimental level, the water level range is ±20mm,the rate of water level range is ±0.02mm/ms, the control valve range is ±20mm in the vicinity of the equilibrium point , which correspond to the seven fuzzy terms {large negative; middle negative; small negative; zero;small positive;middle positive;large positive},corresponding fuzzy symbols is{NB, NM, NS, O, PS, PM, PB}.

According to experience, choosing Gaussian distribution function as the membership functions for controller input and output fuzzy variables [8]:

$$f(x,\sigma,c)=e^{\frac{(x-c)^2}{2\sigma^2}} \quad . \tag{1}$$

The output fuzzy variableturn into fuzzy controller through anti-blur according to center of gravity method [9] :

$$\mu=\frac{\sum_i f_i\mu_i}{\sum_i f_i} \quad . \tag{2}$$

The fuzzy rules were established according to experience, for example: When the water level is large negative(the actual water level is lower than the normal water level), the water level change is small negative(the actual water level is far from equilibrium point), when the water flow is less than the steam flow, the valve position is below the equilibrium point. In order to restore to normal water level,the flow of feed water should be greater than the flow of superheated steam,for restoring the balance point as soon as possible, the amount of valve opening should be larger (large positive). Therefore, the fuzzy rules was built as shown in tab 2.1.

TAB 2.1 FUZZY RULES

OUT EC E	NB	NM	NS	O	PS	PM	PB
NB	PB	PB	PM	PM	PS	PZ	O
NM	PB	PM	PM	PS	PZ	O	NZ
NS	PM	PM	PS	PZ	O	NZ	NS
O	PM	PS	PZ	O	NZ	NS	NM
PS	PS	PZ	O	NZ	NS	NM	NM
PM	PZ	O	NZ	NS	NM	NM	NB
PB	O	NZ	NS	NM	NM	NB	NB

The Setting of State Point

Because the fuzzy control can directly calculated valve valve position through the error and error rate of change , it is faster than the PID control ,however, the fuzzy control only can be adjusted

near the stable point,so ti is not adaptable for changing stable point and system model structure[10],it will reduce the execution speed and stability if use integral part.In this paper, according to state of the boiler,which is the boiler temperature, pressure and flow parameters, it calculate the current valve position that can make the system stabilize, the valve position was used as a stable point of fuzzy control, it makes up the problem that the traditional fuzzy control is larger outside stable point, the paper accord the stable point as state point.

Assumed that in a fixed steam flow, the water level stabilized at the set value, when the value of feedwater flow is equal to steam flow, the corresponding feedwater valve position is accorded as stable point valve for the steam flow. The stable point valve is determined by water pressure, water temperature ,steam flow rates drum pressure and several other parameters, so we can determine the state point by these state parameters.

$$p_B - p_z = \frac{\xi\left(L_p\right) w_f^2}{2\rho} \quad . \tag{3}$$

$$W_f = W_g \quad . \tag{4}$$

$$\rho = f\left(p,t\right) \quad . \tag{5}$$

$$L_p = f\left(\xi\left(L_p\right)\right) \quad . \tag{6}$$

Where: p_B ——pressure of feedwater main tube,MPa；

$\xi\left(L_p\right)$——Valves and valve flow resistance coefficient linear relationship.

Experiment

In order to verify the superiority of the state fuzzy controller, we compared the control effection with single stage PID controller and cascade three impulses level controller systems.

Water perturbation experiments

Fig 3.1 is the response contrast for large water level fluctuations between a fuzzy controller with state-controller and a fuzzy controller without state-controller. As can be seen from the figure, when there is a large fluctuation in the water level, the adjusting speed of both is the same, but when the water level returns near to setting point,there is obvious steady-state error for the fuzzy controller without state-controller,it shows that the introduction of state controller can improve the control precision for fuzzy controller.

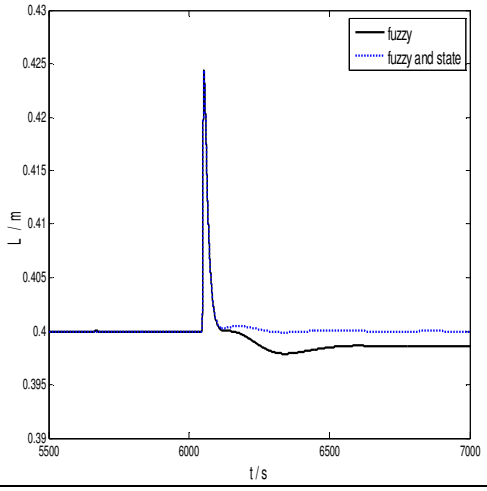

Fig 3.1 The fuzzy controller with state-controller

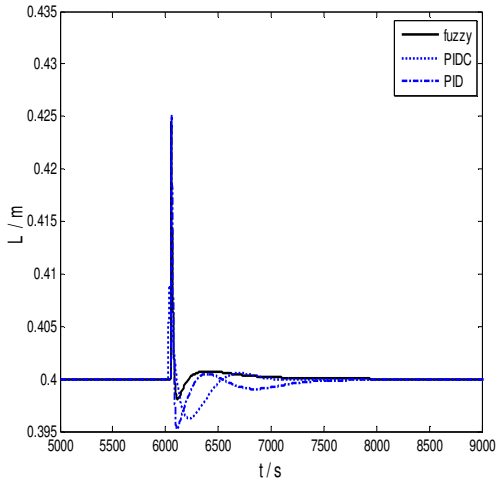

Fig 3.2 The effect of different controller in the same valve opening

The applications of single-stage cascade PID and three impulses level control system is ripe in engineering. Fig 3.2 shows a control effection contrast among single-stage PID controller,three cascade PID controller and fuzzy state controller. As can be seen from the figure, when the water level has great fluctuation, all the three controllers can achieve the setting fast, but from the view of settling time and overshoot, state fuzzy controller was significantly better than the other two groups controller ,which need a shorter regulation time, and at least faster than cascade PID controller 100s, faster than the single-stage PID controller about 300s. This is because the drum control is a non-linear systems, though the PID control response fast in linear system,but fuzzy control more responsive in non-linear systems.

Switching Conditions Experiments

In the marine steam power systems, turbines have three conditions: T1, T2 and T3, supercharged boiler has two conditions: B3 and B4. Tab 3.1 shows the all conditions of marine steam power systems, simulating running station of marine steam power system to inspect the performance of PID and fuzzy controller through changing the gear of boiler and turbine.

TAB 3.1 MARINE STEAM POWER SYSTEM RUNNING STATE

Time t /s	0~ 4000	4000~ 4500	4500~ 5000	5000~ 5500	5500~ 6000	6000~ 6500	6500~ 7000	7000~ 9000
Turbine	T1	T2	T3	T2	T3	T2	T1	T2
Boiler	B3	B4	B4	B4	B4	B4	B3	B4

Fig 3.3 shows the effect of the three controllers to control the water level in different conditions. As can be seen from the simulation results, when steam power system switching conditions,which will have a great disturbance for drum level, state fuzzy controller can rapidly adjust water level to the set value, while the single-stage water level controller PID and Cascade PID controller adjusts the water level slower and have larger overshoot. So,from the perspective of security and stability of the system, only the state fuzzy control system was able to meet the control requirements of supercharged boiler .

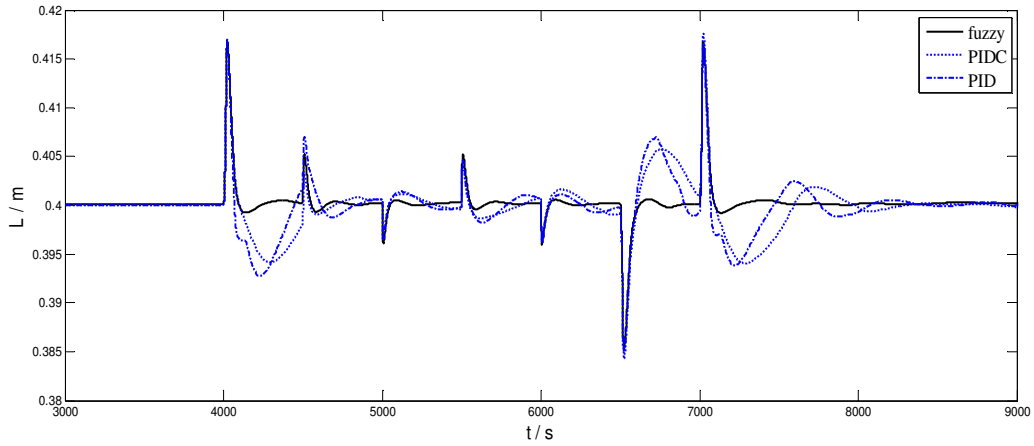

Fig 3.3 The control effection of different controller in running state

Summary

In this paper,a state fuzzy controller was established based on state control theory and fuzzy theory. Compared with single-stage PID controller and cascade PID controller it can draw the following conclusions:

(1)Comparing cascade PID controller with single-stage PID controller, the former has respond faster, shorter time to adjust and better effection of control characteristics.

(2)Comparing the state fuzzy controller with the cascade PID controller,because the state fuzzy controller collects data through the fuzzy processing, which is not too sensitive to changes in water level, smaller overshoot, steady rapidlier, the system better stability.

(3)For the marine steam systems change conditions frequently in accordance with the requirements of the ship Operating conditions,from the perspective of security and stability of the system, only the state fuzzy control system was able to meet the control requirements of supercharged boiler .

Keywords: HPWM; Vehicle lateral stability; high-speed switching valve; Hydraulic control unit

Abstract: The application of the High-frequency pulse width modulation (HPWM) for improving vehicle lateral stability is investigated in the paper. Firstly, a hydraulic control unit (HCU) combined with a high-speed switching valve (HSV) for controlling hydraulic oil pressure by adjusting duty cycle is presented. Then, a typical control strategy is described based on the application of HPWM. Finally, by using a 15dofs vehicle model, a simulation is carried out to investigate the role of HPWM on improving vehicle lateral stability. The results show that HPWM is capable to control the output pressure of HSV accurately and improve vehicle lateral stability effectively.

Introduction

Vehicle dynamic control system used to keep vehicle lateral stability by additional longitudinal forces is an active safety device and developed based on ABS and TCS. Numerous studies focus on the development of control strategy and its implementation [1]. There also exists many literatures on research how to estimate vehicle state parameters such as vehicle speed and side slip angle et al [2, 3]. The effect of hydraulic characteristics on the efficiency of the control system has also been investigated [4]. Currently, low-frequency pulse width modulation (LPWM) makes HSV switch frequently between open and close. Therefore, the procedure can't control braking torque accurately and cause pressure fluctuations and noise. So it deteriorates the efficiency of the control system.

The purpose of the paper is to investigate the application of HPWM in vehicle stability control and the efficiency in improving vehicle lateral stability.

HSV's PWM Control Model

The force acted on the spool of a HSV can be written as

$$m\ddot{x} = F_i(i,x) - F_p(x,\Delta p) - F_k(x) - F_c(\dot{x}) \tag{1}$$

Where m is the spool mass. x is spool displacement. $F_i(i,x)$ is electromagnetic force. $F_p(x,\Delta p)$ is the fluid dynamic force. $F_k(x)$ is the spring force. $F_c(\dot{x})$ is the damping force. Δp is the pressure differential between inlet and outlet. i is the current.

Fig.1 presents the electromagnetic force of solenoid valve along with the change of current and air gap. As the current increases and the air gap decreases, the electromagnetic force becomes increasing. Fig.2 gives the effects of valve opening and pressure difference on steady flow force of HSV.Solenoid valve usually uses LPWM regulation whose frequency is not more than 100Hz and it can't control pressure accurately. But HPWM regulation with a frequency more than 4000Hz is able

to keep spool in any place and control pressure accurately [5]. Figs. 3 and 4 present the valve opening and electromagnetic force of solenoid valve along with duty cycle and time. The frequency of HPWM is 4000Hz and the duty cycle is changed from 20% to 70%. It is obvious that the status of valve opening increases with the increase of duty cycle and the valve is fully opened when the duty cycle is 70% in fig.3. In addition, the valve opening keeps constant at each duty cycle. The electromagnetic force increases with the increase of duty cycle and keeps constant at a given duty cycle.

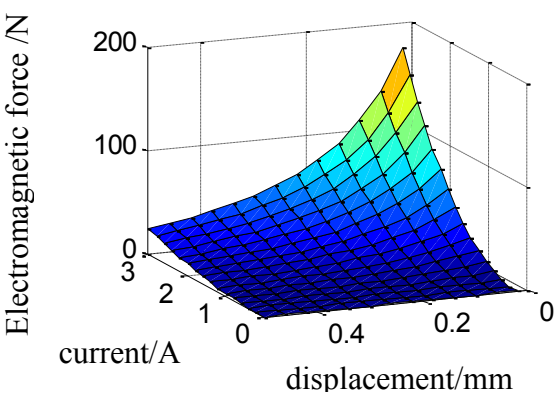

Fig.1 Electromagnetic force

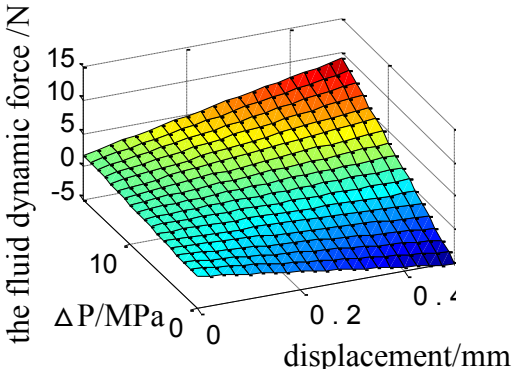

Fig.2 Dynamic forces of fluid

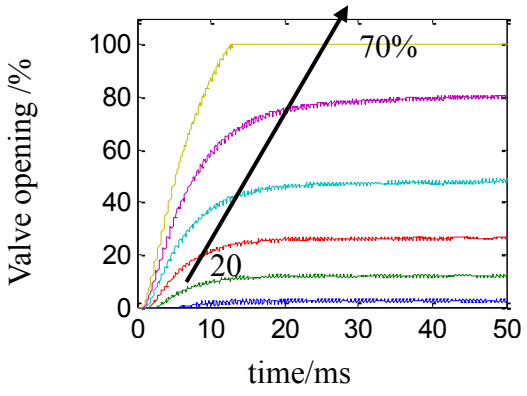

Fig.3 Valve opening with HPWM

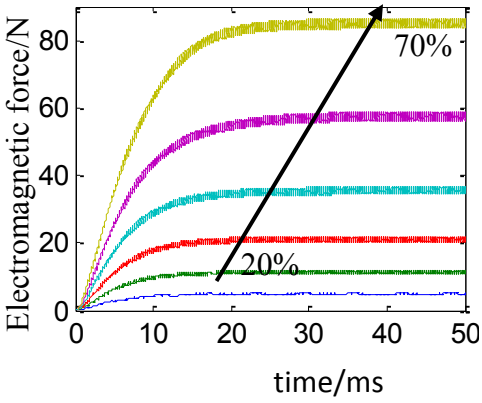

Fig.4 Electromagnetic force with HPWM

Control strategy

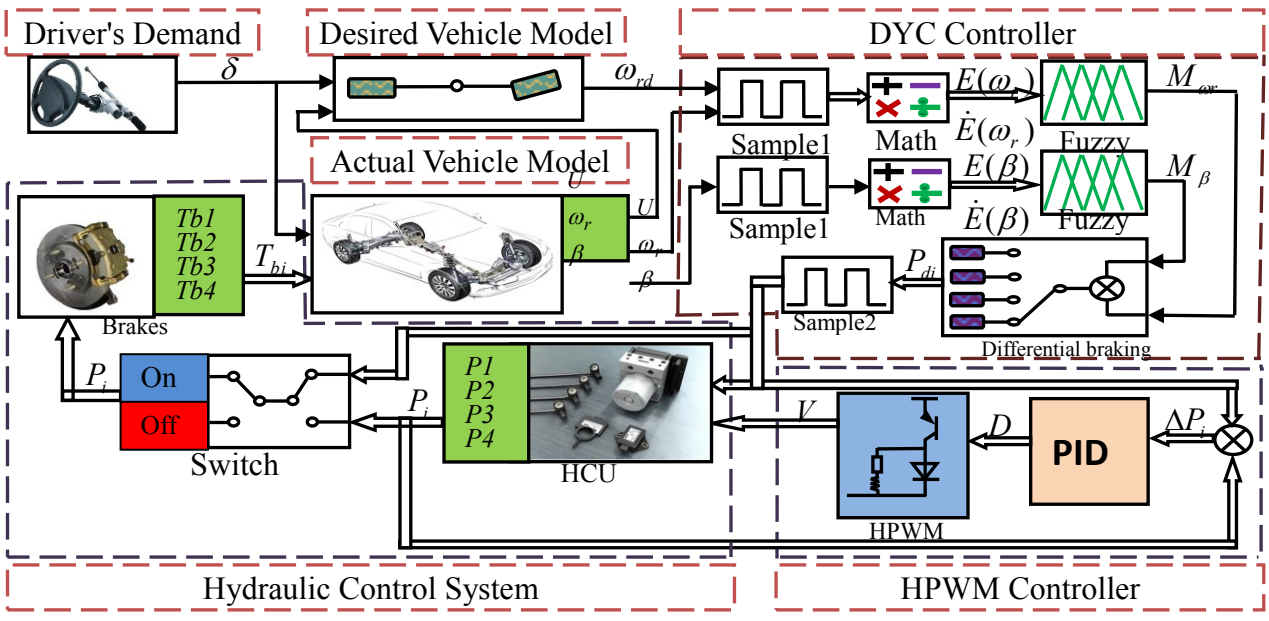

Fig.5 Flowchart of control strategy

The flowchart of control strategy is shown in Fig.5. There are 6 parts in the flowchart. Driver's demand model is used to obtain driver's input. Desired vehicle model is to demonstrate ideal trajectory and output ideal yaw rate ω_{rd}. Actual vehicle model have 15dofs used to present an actual vehicle. The DYC controller with 2 fuzzy controllers is used to control sideslip angle and yaw rate. Sample1 is used to obtain vehicle dynamic parameters as shown in the flowchart with a frequency of 25Hz. The output of DYC controller is corrective moment which is done by differential braking pressure P_{di} in assigned brake system. The high-frequency pulse voltage (4000Hz), whose duty cycle is regulated by PID in HPWM model, is used to make sure that the output pressure P_i close to ideal pressure P_{di} in HCU. Sample2 ensures that the output frequency of P_{di} is 10Hz. Finally, P_i is converted into braking torque which is used to control vehicle lateral stability. Switch is used to debug the control system such as with or without control, with considering the dynamic characteristics of the hydraulic control unit (with HCU) or not.

Simulation and Analysis

The performance of strengthening vehicle lateral stability by using HPWM is evaluated through numerical simulations of vehicle response to a fishhook wheel input. Road coefficient is 0.85. The initial vehicle speed is 80Km/h. The simulation is subjected to without control, with HCU and without HCU in order to compare vehicle lateral stability.

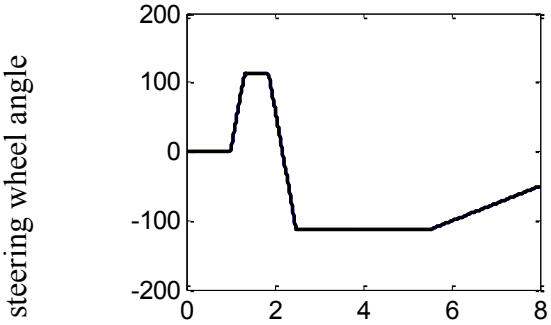

Fig.6 Steering wheel angle

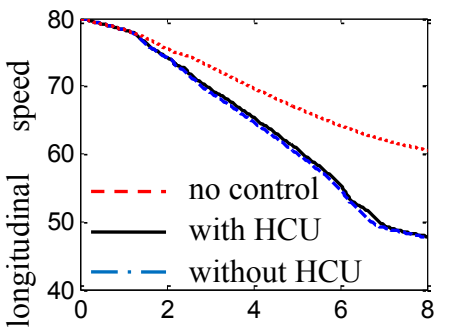

Fig.7 Longitudinal speed

Steering wheel angle is shown in Fig.6. It is zero in the first second, then changes from 115°to -115°in the middle 1.5 seconds and maintains 3 seconds, finally gradually closes to zero. Fig.7 gives the information of vehicle longitudinal speed. Red dashed shows vehicle speed without control. The vehicle speed with HCU control is shown via solid black line. Blue dotted line shows vehicle speed without HCU control. It indicates that the 3 vehicles longitudinal speed with resistance acting is the same and gradually decreases in the first 1 second. The vehicle longitudinal speed without HCU control decreases faster than it with HCU control, but without control decreases the fastest in the remaining time. That because, compared with speed without control, the speeds without HCU control and with HCU control is exerted braking force at an assigned tire and braking force with HCU control is smaller than it without HCU control.

Vehicle tracks are presented in Fig. 12. They are ideal trajectory with green dotted line presented, trajectory without HCU control via blue short dashed, trajectory with HCU control via solid black line and trajectory without control via red long dashed. Trajectory with HCU control and trajectory without HCU control are all could closed to ideal trajectory, but the Trajectory without HCU control is more closer. The maximum difference between trajectory with HCU control and trajectory

without HCU control reaches to 1.5m. The trajectory without control is obviously far away from the ideal trajectory. Fig. 9 gives the information of yaw rate. The yaw rate without control is shown via red long dashed. The solid black line and blue short dashed shows yaw rate with HCU control and without HCU control. The ideal yaw rate is presented by green dotted line. It is obvious that the yaw rate with HCU control and without HCU control is close to ideal yaw rate well, but the yaw rate without control is far away ideal yaw rate.

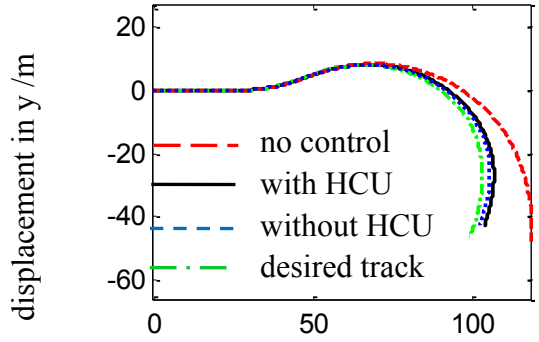

Fig.8 Comparison of tracks

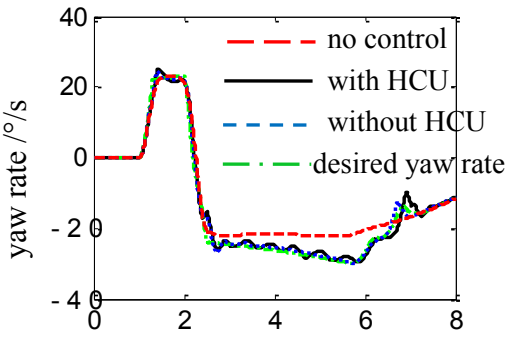

Fig.9 Comparison of Yaw rate

Fig.10-12 give wheel cylinder's brake pressures, braking torques and wheel speeds on each wheel. FL, FR, RL and RR present left tire of front axle, right tire of front axle, left tire of rear axle and right tire of rear axle. Ideal value is shown via green dashed. Solid black line describes the value with HCU control. Blue dotted line presents the value without HCU control. It is shown from Fig.10 that the wheel cylinder pressures follow the tracks of ideal value well, so it proves that HPWM could accurately control output pressure. The normal force translated from inside tire to outside tire in turning in that the resultant force in longitudinal and lateral at inside tire of rear axis gets physical limit, so the peak braking torque without HCU control can't reach ideal peak braking torque as well as the peak braking torque with HCU control. Although the braking torques without HCU control is mostly as the same as the braking torques with HCU control on FL, FR, and RL, it is deferent on RR and the braking torque with HCU has some fluctuations on RR. There are the same tendencies in Fig.12. It indicates that the dynamic characteristics of the hydraulic control unit influence the additional yaw moment with DYC Controller outputting.

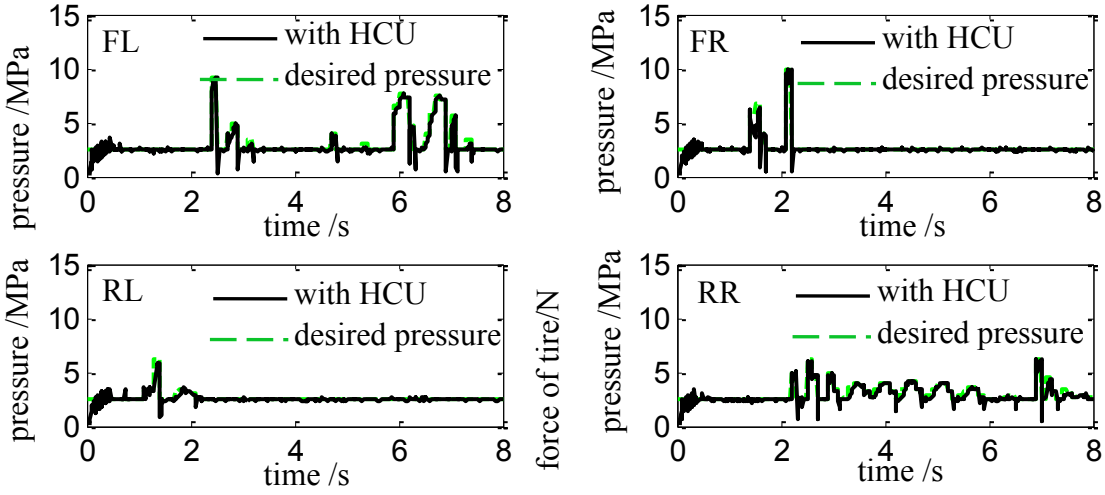

Fig.10 Pressure of brake cylinder

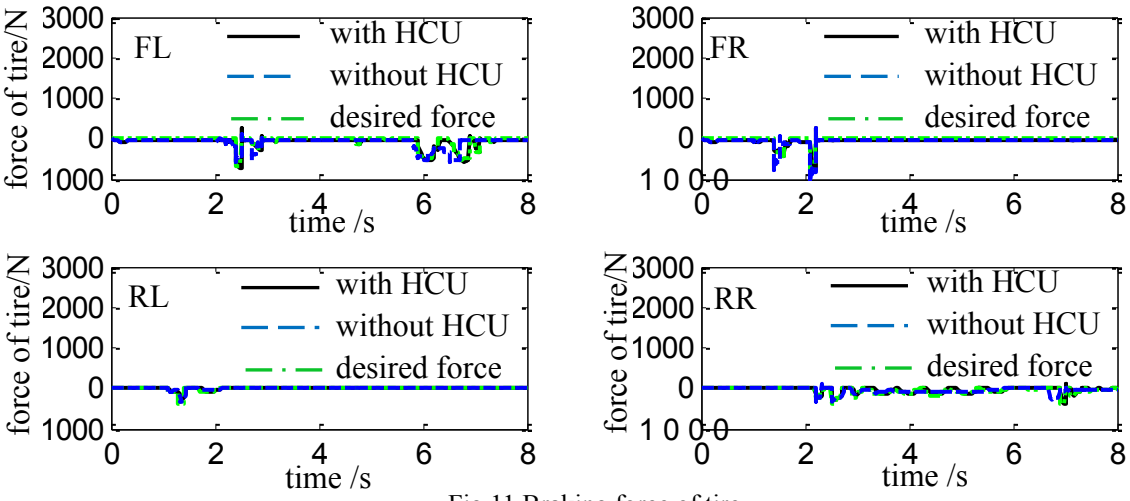

Fig.11 Braking force of tire

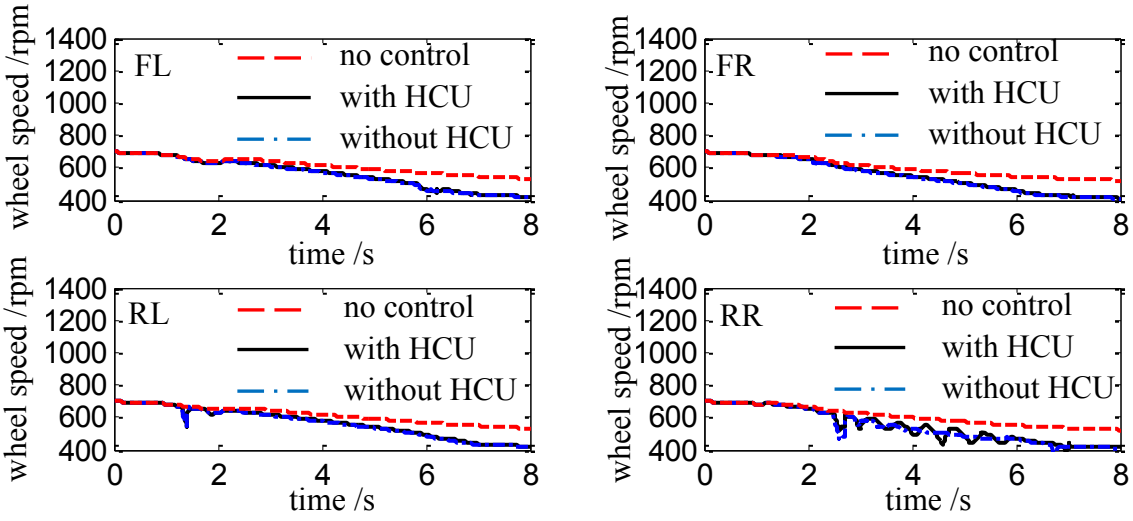

Fig.12 Wheel speed of tire

Summary

(1) The output pressure of HCU can accurately follow the ideal pressure with HPWM control. Compared with LPWM, HPWM not only adjusts the output pressure more accurately and improve vehicle stability efficiently, but also it can reduce the fluctuations of braking pressure.

(2) The entire control system for vehicle lateral stability composed of solenoid valve, HCU and control strategy is close to actual system. Analysis result shows that the dynamic characteristics of HCU have influence on the efficiency of vehicle lateral stability.

Keywords：power predication, the historical data, photovoltaic power generation, de-noising

ABSTRACT ：The accuracy of power prediction of photovoltaic power generation will be reduced if there are noises in the historical data of photovoltaic power generation. It is necessary to eliminate noises in the historical data. First, the power generation can be arranged in a two-dimensional data set by date. Secondly, the grayscale image matrix will be obtained after data normalized. Thirdly, two-dimensional wavelet based image de-noising method will be used in the matrix de-noising. Finally the real historical data will be obtained through anti-normalization the matrix which is already de-noised. We will analyze its results feasible and effectiveness.

INTRODUCTION

Derived from the data collection and monitoring database data is not only the foundation of photovoltaic power prediction and power characteristics, but also the basis of grid control. As the amount of data, data monitoring process will inevitably be a certain degree of error interference, this will directly affect the photovoltaic power prediction accuracy as well as mastery of the PV output characteristics of a negative impact. Therefore, high-accuracy photovoltaic output data for the future smart grid power system real-time scheduling and planning is very important. After more and more small-scale PV systems such as building-integrated photovoltaic (BIPV), etc. connected into the grid, the challenge of PV output prediction for the next day is getting more and more important[1-2]. Therefore, in order to more accurately predict photovoltaic system generating capacity curve, it is necessary to de-noising the abnormal data to improve data quality and reduce the problem of randomization PV impact on the grid.

Today, the signal processing has become an important part of contemporary science. The ideal tool for the nature which is stable and unchanging over time signal processing is Fourier. However, in practice, most of the signal is unstable, in particular for non-stationary signals is the wavelet analysis tool. Our PV data is discrete data signal is non-stationary. This article will use the wavelet transform of the PV data signal processing.

So far, the data de-noising research focuses on the load forecasting research, mostly one-dimensional de-noising [3-4]. Given a certain degree of de-noising dimensional limitations, this paper made a two-dimensional photovoltaic power data de-noising. The horizontal axis represents the coordinates adjacent to the date, the vertical axis represents the node at different times of the same date. Then the matrix formed through the normalization process, Get each element in the matrix between 0-1. This matrix can be seen as a gray-scale image matrix. Followed by the two-dimensional wavelet-based image de-noising . Finally, anti-normalization, get de-noised PV output data.

Wavelet Transform De-Noising

This is wavelet threshold shrinkage method [5-6]: Wavelet transform of $f(k)$ which contains noise, M represents the number of layers. The k_{th} frequency coefficients of the j_{th} layer is called wavelet coefficients $w_{j,k}$. According to the different nature of the noise and signal, we threshold processing to $w_{j,k}$, then the new wavelet coefficients $\tilde{w}_{j,k}$ is obtained. The de-nosied signal will be obtained by reconstructing $\tilde{w}_{j,k}$.

Determination of the threshold value

Threshold directly affects the denoising results. Smaller threshold is able to retain more of the wavelet coefficients and image information, but retained the noise is greater; While larger threshold value makes the picture in some useful high-frequency information is removed.

Existing threshold selection criteria, including the fixed threshold criterion, mixed threshold criterion, unbiased risk estimation criteria and Minimax threshold criteria, etc. [7]. Compared to the above criteria, a fixed threshold criterion is relatively simple and de-noising better. This article is taken globally fixed threshold de-noising method, The threshold is

$$T = \sigma\sqrt{2\log_2 N} \tag{1}$$

Where σ Is the noise standard; N is the length of the signal.

$$\sigma = \frac{\left|\overline{w}_{j,k}\right|}{0.6475} \tag{2}$$

Where $j = 1,2,\cdots M$; $k = 1,2,\cdots,N_j$, N_j are the high-frequency numbers after the level j resolved, $\overline{w}_{j,k}$ is the arithmetic mean value of the sequence of number $\{w_{j,k}\}$.

The selection of threshold function

Soft threshold function de-noising has some flaws [5-6]. So we use the semi-soft threshold function. Mathematically expressed as follows:

$$\tilde{w}_{j,k} = \begin{cases} (1-\mu)w_{j,k} + \mu\,\mathrm{sgn}(w_{j,k})(|w_{j,k}| - T) & |w_{j,k}| \geq T \\ 0 & |w_{j,k}| < T \end{cases} \tag{3}$$

$$\mu = \frac{T}{|w_{j,k}|}\exp\left(-\frac{|w_{j,k}| - T}{|w_{j,k}| + T}\right) \tag{4}$$

Where μ is the weighting factor.

It can be proved that the formula in both continuous threshold function, and in the threshold greater than the threshold within a continuous wavelet threshold higher order derivatives, it is simply hard threshold or soft threshold values are not available.

PV DATA DE-NOISING PROCESS

In summary, for short-term prediction of photovoltaic output data de-noising wavelet analysis as follows:

Step1：Select the n days before the test and 96 time breakpoint per day as data sample nodes

Step2：This matrix normalization processing, the new matrix is a two-dimensional gray-scale image matrix. Each element in the matrix represents the brightness in the image.

Step3：Wavelet decomposition of the image in step 2 and select the appropriate wavelet for the original signal $f(k)$, for M-layer wavelet decomposition，finally we obtain a series of wavelet coefficients $w_{j,k}$。

Step4：The wavelet decomposition of the high-frequency coefficients thresholding, The $w_{j,k}$ for semi-soft threshold function processing, to obtain the estimated coefficients $\hat{w}_{j,k}$.

Step5：Reconstructing the two-dimensional images using $\hat{w}_{j,k}$ and we get the signal $\hat{f}(k)$ which has already been de-noised.

Step6：Anti-normalize $\hat{f}(k)$ which has been already de-nosing and get de-noised PV output data.

EXAMPLES OF EFFECTIVENESS ANALYSIS

Here we select U.S. Sheldon Village 2010 Years 20 days per 96 time points photovoltaic output data, a total of 1920 sample data. Using matlab wavelet transform data box, decomposition level of M = 3，Wavelet selection db4. The next will be from the de-noising performance and accuracy for the photovoltaic power prediction accuracy to evaluate and analyze.

Analysis of photovoltaic data de-noising

For image de-noising after evaluation of the effectiveness of the indicators, including peak signal to noise ratio (PSNR) and root mean square error (RMSE)[8-10]， $f(x,y)$ as a size of $M \times N$, the quantization level is $0,255$：

$$RMSE = \left(\frac{1}{MN} \sum_{x=0}^{M-1} \sum_{y=0}^{N-1} \left(f(x,y) - \tilde{f}(x,y) \right)^2 \right)^{\frac{1}{2}} \tag{5}$$

$$PSNR(dB) = 10 \log_{10} \frac{255^2}{(RMSE)^2} \tag{6}$$

$\tilde{f}(x,y)$ is the image reconstructed after de-nosing.

Table 1 shows the soft threshold and hard threshold and the actual use of semi-soft wavelet threshold de-noising comparison results. Table 1 shows the results of the indicators can be seen, based on semi-soft thresholding wavelet method is better than the hard threshold and soft threshold method.

TABLE 1 DIFFERENT THRESHOLD FUNCTION DE-NOISING RESULTS

Threshold function	RMSE	PSNR/dB
Hard threshold	3.54×10^{-4}	38.75
Soft thresholding	8.73×10^{-5}	40.24
Semi-soft threshold	5.31×10^{-5}	44.60

Accuracy assessment of daily electricity generation

Sparse Bayesian algorithm proposed theoretical model based on support vector machines by Dr. Michael E. Tipping in 2001. Probabilistic model introduced by artificial intelligence methods can get rid of the vast majority of errors encountered interference. At present, this method has been used in the power load forecasting[11-12]. We will use this method for photovoltaic power generation data preprocessing before and after pretreatment, evaluate the accuracy of using the root mean square error indicators.

Table 2 shows a month in predictions, from which we can see through to the noise after most days, root mean square error will be reduced. From the point of view throughout the month of RMSE, de-noised 0.08 is better than before de-noised 0.088 so that achieve the purpose of improving the prediction accuracy

CONCLUSION

We can de-noising PV data while maintaining PV power's vertical and horizontal time on the basis of trends. The original data after de-noising, PV power forecasting can provide higher quality input data in order to reach a higher level of prediction accuracy.

Keywords: KAZE algorithm, transmission line, insulators detection

Abstract: Transmission Line obstacle detection technology is one of the hot spots of computer vision and transmission line inspection robot system.As the most common obstacle of inspection robot,correctly identify of insulators can help improve the reliability and accuracy of self-inspection. Low robustness of traditional detection algorithm can not meet the requirements on insulators detection when dealing with complex environment. To solve the above problem, a transmission line insulators detection method based on KAZE algorithm is given. The feature extraction is done in the nonlinear scale space, and feature vectors are formed with M-SURF algorithm, what's more, feature vectors detecting is worked through the nearest neighbor algorithm as matching criteria and RANSC generated algorithm. Experimental results show that the effect of insulators detection algorithm based on KAZE detect faster and also make a good performance on accuracy and robustness.

Introduction

In the study of transmission line inspection robot , the real-time detection and identification of obstacles is a very important technology , which refers to the line inspection robot charged in case of crawling along the ground line to identify shock hammer, insulators , suspension clamps , towers and other obstacles independently, thus improving the reliability and accuracy of the self-inspection[1]. In recent years, transmission line insulators detection has aroused general interest in the field of transmission line insulators detection. Currently, the method of transmission line insulators detection can be divided into three parts: multi-sensor-based detection , machine vision based detection and active learning based detection[2]. Among them, the detection method based on machine vision is simple and effective , which mainly divided into feature detection, structural constraints detection,stereo vision detection. These three methods can give a good detection result , but they are sensitivity of the complex images[3-6]. To solve this , this paper propose a transmission line insulators detection system using KAZE algorithm , which enhance the robustness of the system and help to improve the robot navigation's accuracy and sensitivity .

KAZE feature detection algorithm is based on nonlinear scale-space , it construct stable nonlinear scale space by additive operator splitting algorithm (AOS) and variable conduction diffusion[7]. It has outstanding robustness, high precision and partial match performance compared with Harris, SIFT, SURF and other traditional detection algorithm, what's more,it's insensitive with scale, affine, perspective and illumination invariance which can make it maintain better detection results for insulators detection under complex background.

KAZE Features

KAZE algorithm is based on nonlinear scale space, which detection includes four steps: construction of the nonlinear scale space , feature detection, precise positioning of features , generation of feature vector .

Construction of the Nonlinear Scale Space

Scale-space theory first introduced in the field of computer vision, which aims to simulate multi-scale features of image data, its main idea is to KAZE algorithm construct nonlinear diffusion filtering with additive operator splitting algorithm (AOS) and variable conduction, and you can take any step to construct a stable nonlinear scale space[8]. Eq.1 shows the nonlinear diffusion formulation:

$$\frac{\partial u}{\partial t} = \mathrm{div}(g(|\nabla u_\sigma(x,y,t)|) \bullet \nabla u_\sigma) \quad . \tag{1}$$

Where u is image luminance,div is divergence,time t is scale parameter, ∇u_σ is the gradient of a Gaussian smoothed version of the original image, $g(|\nabla u_\sigma(x,y,t)|)$ is conductivity function which can be shown as Eq.2:

$$g(|\nabla u_\sigma(x,y,t)|) = \exp(-\frac{|\nabla u_\sigma|^2}{k^2}) \quad . \tag{2}$$

The contrast parameter k determines the mount of edge information to be keep.

KAZE algorithm discrete the scale space in logarithmic steps arranged in a series of o octaves and s sub-levels. Make sure that each image has and the the same resolution with original image. The octave and sub-level indexes are mapped to their corresponding scale σ through the following Eq.3:

$$\sigma_i(o,s) = \sigma_0 2^{\sigma+\frac{s}{S}} \qquad o \in [0,\cdots,o-1],\ s \in [0,\cdots,S-1],\ i \in [0,\cdots,N]. \tag{3}$$

Where σ_i is the scale level in pixel,σ_0 is the base scale level and N is the total number of filtered images.

Feature Detection in Nonlinear Scale Space

KAZE features can be achieved by finding normalized Hessian local maximum at different scales.Hessian matrix is calculated as Eq.4:

$$U_{\mathrm{Hessian}} = \sigma^2 (U_{xx} U_{yy} - U_{xy}^2) \tag{4}$$

We should generate Hessian determinant value of each pixel in each level first, and then compare with its adjacent points to find local maximum. As it's shown in Figure 1,the middle point

is compared with its eight adjacent points at same scale and the 9*2 points at scale corresponding vertically :

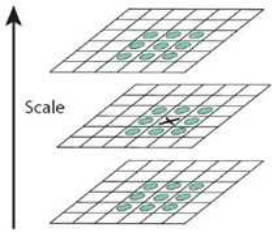

Fig.1 Feature Detection

Precise Positioning of Features

KAZE algorithm determines the location and scale of key points accurately by using Taylor expansion spatial of spatial scales function, while removing the key points with low-contrast edges and unstable response to enhance the matching stability and noise immunity[9]. the Taylor expansion of spatial scales function can be shown as Eq.5:

$$U(x)=U+(\partial u/\partial x)^T x+½\ x^T(\partial^2 U/\partial X^2)x \tag{5}$$

Feature Description

We find the dominant orientation in a circular area of radius $6\sigma_i$ with a sampling step of size σ_i. In order to find the dominant orientation,first order u_x and u_y are weighted with a Gaussian centered at the interest point, make sure that the near feature points with a large contribution and the feature points away with a small contribution. Then,the derivative responses are represented as points in vector space and the dominant orientation is found by summing the responses within a sliding circle segment covering an angle of 60°(Figure 2).From the longest vector the dominant orientation is obtained.

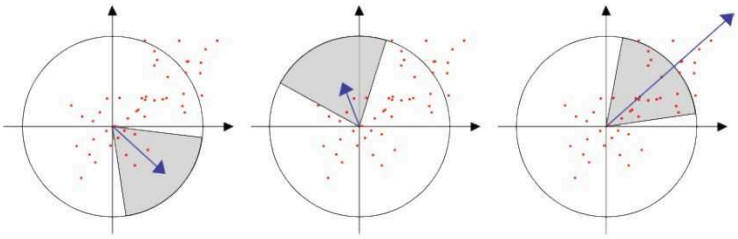

Fig.2 Finding the Dominant Orientation

We use the M-SURF algorithm to get the descriptor. For a detected feature at scale σ_i,we first get a $24\sigma_i \times 24\sigma_i$ rectangular grid centered on the feature, this grid is divided into 4×4 subregions of size $9\sigma_i \times 9\sigma_i$ with an overlap of $2\sigma_i$. Each subregion are weighted with a Gaussian kernel ($\sigma_1=2.5\sigma_i$) and get a descriptor vector dv , dv can be shown as Eq.6:

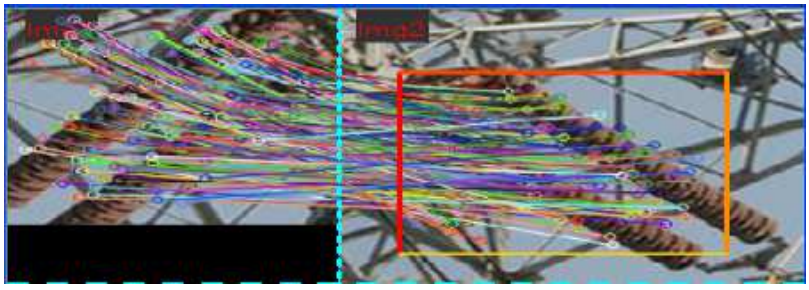
$$dv = (\Sigma U_x : \Sigma U_y : \Sigma|U_x| : \Sigma|U_y|). \tag{6}$$

Then,each subregion vector is weighted using a Gaussian($\sigma_2=1.5\sigma_i$) defined over a mask of 4×4, and it is normalized to remove the impact of light. In a word,we can get 64-dimensional vector description for each feature point.

Matching Feature Description

Feature description matching can be done after generating KAZE feature vector. For the purposes of transmission line insulators detection, getting more accurate and uniform distribution of key points is important,so that we can reduce the overall error by data fitting. According to Lowe's ideas, for the matching points, if the nearest neighbor and next nearest neighbor Euclidean distance ration is less than a certain threshold, then the matching points can be accepted . Then,false matching points are further eliminated using the feature set of geometric constraint relations by RANSAC algorithm.

Experiment Results and Discussion



Experimental platform is a personal computer with the frequency 2.8GH z, memory 1.99G, windows XP operating system, experimental environment is VS2010. This paper use 100 different types of insulator images(60 with insulators,40 without insulators)to fully verify the experiment. The images are with size of 265×240 ,and they are under complex background with different geometric and photometric transformations such as image blur, lighting, viewpoint,scale changes,zoom compression. Below is results of two sets among them. The first group includes insulator (Fig. 3), it was rotated 90^{o} counter-clockwise, stretched 1.8 times on the horizontal,the result shows that the insulator can be detected correctly, and can determine the position of insulator(Fig.3(c)). The second group without insulator(Fig.4),it was 1.5 times enlarged, distortion 5^{o} on horizontal,and they are also impacted by light and noise.The result shows that the image does not include the insulator (Fig.4(c)).

Fig.4 Result of Image without Insulator

Experimental results show that KAZE algorithm can extract more feature points under complex background and various distortion in images.With the real-time ensuring,KAZE algorithm can accurately determine whether the image contains insulator, and if the insulator is detected, it can determine the location of the insulator, thereby providing a basis for the inspection robot's autonomous navigation and obstacle avoidance.

TABLE1 DETECTION RESULT OF INSULATORS

	Images with Insulators	Images without Insulators
Total Number	60	40
Correct Number of Detection	59	40
Detection Rate	98.33%	100%
Average Detection Time（ms）	8596	7605

Summary

This paper has presented a novel transmission line insulators detection methods based on KAZE algorithm. It extract insulators feature points based on nonlinear scale space, then use M-SURF algorithm to generate feature descriptor, and finally through the nearest neighbor criteria and RANSC algorithm matching the feature descriptors, thereby we can obtain detection results. The experimental results show that this method can accurately detect whether an image contains insulators, and it has good robustness, high accuracy and high speed, so that it can improve real-time avoidance performance of autonomous inspection robot.

Keywords: transmission line, lightning strike, integral, wavelet transformation

Abstract: Transient signals caused by lightning strikes on transmission lines may interfere with the distance measuring devices relying on traveling wave. A synthesized method based on the additional components of disturbed current is proposed to distinguish between lightning interference, lightning fault and short-circuit fault. Firstly, since the disturbed current waveform generated by lightning interference and faults are distinct in the time domain, transient current components over and below timeline are respectively integrated to identify lightning interference from faults. And then, due to the distribution differences of current in the frequency domain, multi-scale transformation of wavelet is adopted to analyze the energy spectrum of transient current generated by short-circuit fault and faults of lightning. Numerous PSCAD simulation results demonstrate the proposed method is valid and correct.

Introduction

Based on the transient fault traveling wave, distance measuring devices on transmission lines achieve fault locations by detecting the time at which the traveling wave reaches the bus. Meanwhile they have advantages of rapid location and high accuracy[1-3]. Lightning strikes can have serious interference in the accuracy of those devices. Therefore, it is significant and practical to identify faults and interference accurately in order to take protective and repairable measures correspondingly.

At present, some researchers have started to pay attention to the identification of lightning and achieved certain results. [4] proposes the consistency coefficient of the traveling waveform and utilizes its size to distinguish between interference and faults. It is quite sensitive, but the data window is too long to the traveling wave protection. [5] just analyzes the induced lightning regardless of the direct lightning. [6] takes advantages of the changing trends of zero-mode fault voltage in a period of time to identify shielding and back striking lightning. However, this method aims at identifying lightning strikes on DC transmission lines, the effectiveness of AC system has not been verified.

In this paper, a 220kV electromagnetic transient model is set up and different kinds of disturbances are simulated with the use of PSCAD. Relying on the analyses of the existing identification methods, a hybrid approach is proposed to identify lightning strikes. Lightning interference and faults could be seperated by the integral method of additional current in time domain. Afterwards short-circuit fault and most faults of lightning could be distinguished by the energy ratio which is extracted by multi-scale transformation of wavelet in frequency domain.

Lightning Simulation Model of Transmission Line

Since the induced lightning does not act on the transmission lines directly and generates small over-voltage, it is not considered in this paper. At the same time, back striking lightning interference occurs once in a while and has limited impact on the transmission lines. So it is also not researched[7].

The simulation model of a 220kV power system set up with the application of PSCAD shows in Fig.1 and lightning interference, fault of lightning and short-circuit fault are respectively simulated. The measuring lines last for 100 kilometers and adopt the Marti frequency dependent model.

Meanwhile, the arresters make use of the model approved by IEEE and locate at both sides of the transmission line. Towers in the model utilize the conventional horizontal arrangement, double shielding wire furnished on the top. And the insulators employ the voltage controlled model and flash at 1200 kV. 2.6/50μs double exponential waveform is applied to the lightning current and the wave impedance of lightning channel is 300Ω. In the simulation, the sampling frequency chooses 500 kHz and the simulation period takes 2ms.

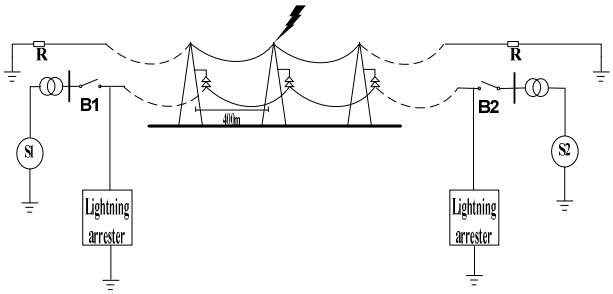

Fig.1 Simulation System of 220kV Transmission Line

Analyses on Transient Characteristics of Lightning Interference and Faults

The transient current measured by CT located at both sides of buses contain rated frequency component and additional component, the former is out of consideration in order to stress the transient characteristics. Because of the electromagnetic coupling between the respective phases, Clarke transformation is applied to decouple the additional current and aerial mode components are studied which is shown in Fig.2~4.

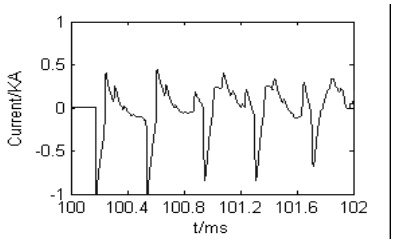

Fig.2 Aerial Mode Current Generated By Lightning Interference

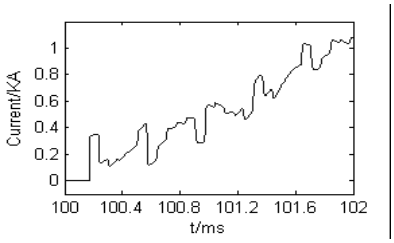

Fig.3 Aerial Mode Current Generated by short-circuit Fault

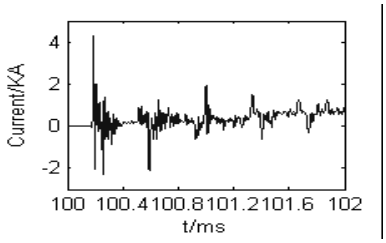

Fig.4 Aerial Mode Current Generated By Lightning Fault

As seen in figures above, the aerial mode current of lightning interference is alternative around the timeline. Furthermore, positive and negative peaks appear alternately. However, the current of short-circuit fault incline to one side of the timeline and can change monotonously overall. Transient signal of lightning fault is similar to that of lightning interference in the beginning stage while presents the characteristics of short-circuit fault in the later stage.

From analyses of the waveform above, it can be seen that the lightning current waveform is shaking because of the constant reduction of the catadioptric lightning current and the little damped coefficient of the transmission line system. While, when the short-circuit fault occurs, it is equivalent to attach a rated frequency power to the fault point which makes the current waveform monotonous.

According to the analyses above[8], an integral identification method is put forward and the identification criterion S is defined. The integral of transient current waveform over and below timeline respectively make up the original signals $I_1$and I_2 which are expressed as

$$I_1 = \int_{t_0}^{t_0+\tau} i_+(t)dt\,, \tag{1}$$

$$I_2 = \int_{t_0}^{t_0+\tau} |i_-(t)|\, dt\,, \tag{2}$$

$$S = \sqrt{(I_1 - \bar{I})^2 + (I_2 - \bar{I})^2}\,, \tag{3}$$

where $i_+(t)$ and $i_-(t)$ are the transient current components over and below timeline. I_1 and I_2 act as the integral of current in τ period. t_0 is the time detecting the mutation of transient current. $\bar{I}$ is the average of I_1 and I_2. Then due to the symmetry in the waveform, I_1 and I_2 should be very approaching and S is small in the lightning interference, but they differ quite a lot and S becomes huge as the faults take place.

Table 1 is the simulating results of lightning interference and faults occur 50 kilometres away from bus B1.

TABLE.1 CHARACTERISTICS IN TRANSMISSION LINE DISTURBANCES

Type of faults	I_1[kA·ms]	I_2[kA·ms]	S
Single-phase ground	179.64	0.0011	127.03
Two-phase fault	509.02	0.0011	113.82
Two-phase ground	421.99	0.0011	298.34
Three-phase fault	271.65	0.0011	192.09
Lightning fault	391.15	51.02	240.51
Lightning interference	86.94	98.03	7.84

Data in the table above apply that identification value of lightning interference is much less than that of faults.The biggest S in the interference is 7.84, while the smallest that of faults is 113.82.

In this way, S_0 which is 50 can be defined as the threshold value. If $S < K_1 S_0$ (K_1 is the reliable coefficient, defined as 1.5) lightning interference must be determined, on the contrary faults can be determined. It should be learnt from the results that this identification criterion is able to effectively distinguish between lightning interference and faults.

Analyses on the Wavelet Energy Spectrum of Lightning and Short-circuit Faults

Researches on the Multi-scale Transformation of Wavelet

Based on the multi-resolution analyses, fast wavelet transformation makes use of the orthogonal wavelets to decompose transient signals into several components at different scales. Assuming transient signal x(n) has been converted, $D_J(k)$ and $A_J(k)$ separately act as coefficients of high-frequency and low-frequency components in time k of scale J. Therefore the frequency range of the signal which is generated after the single branch reconstruction shows as

$$\begin{cases} D_J(k):[2^{-(J+1)}F_s, 2^{-J}F_s] \\ A_J(k):[0, 2^{-(J+1)}F_s] \end{cases}, \tag{4}$$

where F_S is the sampling frequency. And the biggest scale is M. Hence the former signal x(n) may be expressed as the sum of components.

$$x(n) = D_1(n) + A_1(n) = D_1(n) + D_2(n) + A_2(n)$$
$$= \sum_{J=1}^{M} D_J(n) + A_M(n)\,, \tag{5}$$

After the fast wavelet transformation, the sum of squared wavelet coefficients at different scales can be extracted as the signal energy of corresponding frequency range. The formulae display as

$$E_{DJ} = \sum_{K=1}^{N} |d_J(k)|^2\,, \tag{6}$$

$$E_{AJ} = \sum_{K=1}^{N} \left| a_J(k) \right|^2 , \tag{7}$$

where E_{DJ} and E_{AJ} are the energy of high-frequency and low-frequency components at scale J.

According to the theory of Parseval, a correlation between the energy of wavelet transformation at each scale and the original signal energy is built. Therefore the effective identification of varied transient signals can be achieved by the research on the energy distribution feature in distinct frequency bands[9].

Analyses on the Wavelet Energy Spectrum of Various Disturbances

In this paper, wavelet db4 is applied to decompose the aerial mode current components which are 2ms after diverse faults occur to 6 levels. The results show as

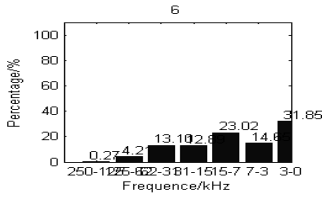

Fig.5 Energy Distribution of Shielding Lightning Fault

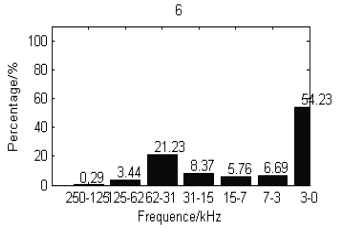

Fig.6 Energy Distribution of Back Striking Lightning Fault

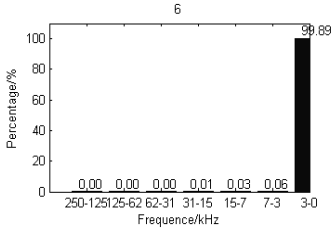

Fig.7 Energy Distribution of Short-circuit Fault.

Comparing Fig.5, 6 and 7, it can be seen that energy distribution of lightning faults and short-circuit fault vary greatly in high and low frequency bands. Therefore energy ratio criterion K can be defined as

$$K = \frac{E_{DJ}}{E_{AJ}} \quad . \tag{8}$$

All things considered, K_0 which is 0.05 can be defined as the threshold value. If $K > K_1 K_0$ lightning faults can be determined, on the contrary is short-circuit fault. Based on the simulation model showed in Figure 1, mass PSCAD simulations are conducted to verify the effectiveness of the criterion. Results list in Table 2-3.

Summarizing the researches above, it is practicable to identify lightning interference, fault of lightning and short-circuit fault through the integral algorithm of time domain and the energy spectrum of frequency domain obviously. The specific process shows as figure 8.

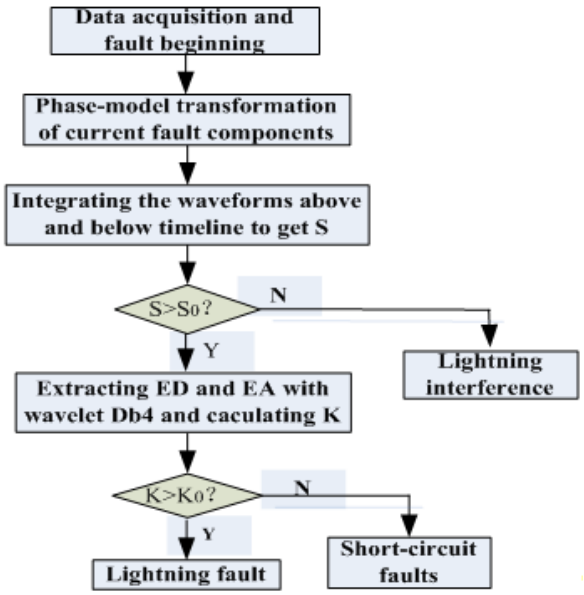

Fig. 8 Flow Chart of the Identification of Lightning Strike Faults

Simulation of Identification and Analyses

Numerous simulations of lightning faults under different current waveform and peaks and short-circuit faults under various transition resistances have been carried out according to the 220kV system shown in Fig1. And part of results are displayed in Table 2-3.

TABLE.2 FEATURES OF LIGHTNING FAULTS

Type	Waveform[us]	Current[kA]	$E_{DJ}[10^6A^2]$	$E_{AJ}[10^6A^2]$	K
shielding	2.6/50	30	423.52	197.95	2.14
		60	2003.4	203.94	9.82
	10/350	30	402.07	178.79	2.25
		60	1892.4	238.89	7.92
back striking	2.6/50	120	60.71	194.22	0.31
		150	190.43	225.59	0.84
	10/350	12	45.57	199.99	0.23
		150	89.56	217.12	0.41

TABLE.3 FEATURES OF SHORT-CIRCUIT FAULTS

Type	Transition resistance[Ω]	$E_{DJ}[10^6A^2]$	$E_{AJ}[10^6A^2]$	K
Single-phase ground	10	0.065	58.95	0.0011
	500	0.0084	3.21	0.0026
Two-phase short circuit	10	5.05	425.61	0.012
	500	0.43	51.96	0.0084
Two-phase ground	10	3.95	303.03	0.013
	500	0.11	13.91	0.0082
Three phase short circuit	10	0.42	137.34	0.0030
	500	0.018	7.27	0.0025

According to the data above, K in the shielding lightning fault is higher than that in the back striking lightning fault. While, the lightning current waveform did not play a major role. With the increase of the lightning current amplitude, K became bigger. In the short-circuit faults, various types had a small effect on K, meanwhile K decreased along with the transition resistance increasing.The smallest K in the lightning faults is 0.23 which is nearly twenty times larger than the biggest K in short-circuit faults, 0.012. Therefore the criterion can effectively identify lightning faults from short-circuit faults.

Summary

This paper proposes an integrated lightning identification method. Firstly, compare the integral of disturbed signal components in time domain to distinguish between lightning interference and faults. Then extract the energy ratio of fault signals by wavelet transformation to identify fault of lightning from short-circuit fault. A large number of simulations considering for numerous fault conditions have proved the synthesized method displayed in this paper is effective and reliable.

Keywords: POE, connection detect, symmetrical architecture, signature resistance, step response

Abstract. POE (Power Over Ethernet) realizes the multiplexing of power transmission and data transmission. To ensure the safety of power supply process, PD (Powered Device), when connected, must be detected by PSE (Power Sourcing Equipment). This article describes the methods of PD detection especially in the symmetrical architecture. The symmetrical architecture means that PSE and PD are connected and either of them can play a role of PSE or PD. In our new approach, signature resistance is replaced by signature capacitance. The connection of PD changes the capacitance load of the system, so the step response can be used to detect the change of capacitance load. This method requires zero static current, which reduces the system power consumption. The theoretical analysis, PSPICE simulation and the experimental results are given.

Overview of POE (Power Over Ethernet)

POE is a power supply technology which transmits electric power via Ethernet cables such as class-5/class-6 unshielded twisted pair (UTP) or shielded twisted pair (STP) etc. POE satisfies the IEEE 802.3af-2003[1] standard. Some small network devices, such as IP phones, network cameras, wireless access points and data terminals, are capable of being powered via Ethernet connection instead of via AC outlet. Its prominent advantage is power transmission on the basis of existing network cables, which consequently simplifies cabling greatly, reduces the construction cost of network infrastructure and will expand the application of Ethernet technology. Its disadvantage is that the power supply to be transmitted should not be very large due to the restriction of the direct-current resistance of twisted pair.

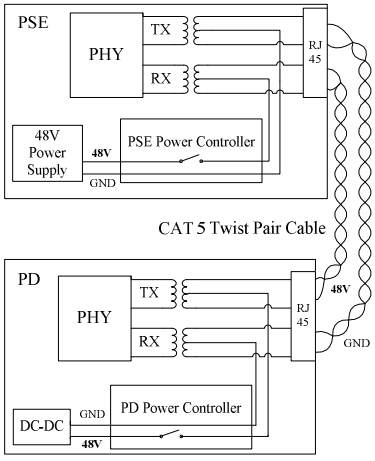

Fig. 1 A simple POE diagram

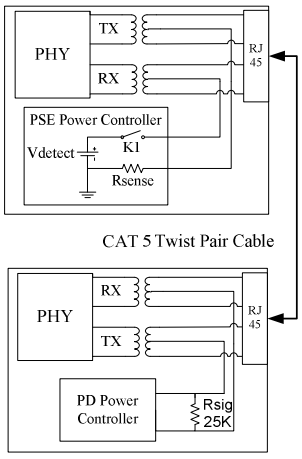

Fig. 2 A PD detection diagram

Fig. 1 shows a simple POE topology diagram. The upper half is PSE (Power Sourcing Equipment), and the lower half is PD (Powered Device). Ethernet data is transmitted differentially and coupled at both ends by high-frequency network adapters. Therefore, adding a 48v common mode voltage difference between transmit pair and receive pair does not affect the data transmission. The

reliability and effectiveness are guaranteed, and the multiplexing of data transmission and power transmission is realized.

PD detection of POE

When no PD is connected to PSE, PSE should not output the 48v power. This allows reducing unnecessary waste of power and prevents the 48v power supply of PSE from being damaged by accidental short circuit. When PD is connected to PSE via twisted pair, PSE should detect automatically that there is PD connected, and then it can output the power supply. In 820.3af, this process is achieved by detecting the signature resistance.

As Fig. 2 shows, PD has a signature resistance R_{sig}[2] of 25KΩ. PSE generates a 2.7v~10.1v voltage V_{detect}, then closes K1 to output the voltage to the twisted pair. It gets the current value by measuring the voltage drop across R_{sense}. When PD is not connected, PSE outputs V_{detect} and then detects that there is no voltage drop across R_{sense}. When PD is connected, as a result of the signature resistance, PSE detects that there is voltage drop across R_{sense}. As V_{detect} and the current value are given, if PSE calculates using volt ampere-characteristic that the signature resistance of the connected PD equals 25KΩ. PSE believes what is connected is a PD, which needs to be powered. Then it enters the next step and outputs 48v power supply. If PD is disconnected afterwards, PSE will detect that output current equals zero, then it will output V_{detect} again and detect continuously until PD is connected.

To detect R_{sig} by outputting V_{detect} of 2.7v～10.1v is safer and more easily controlled than detect R_{sig} by outputting 48v. Because 48v module is a power module, it may be easily burned by accidental short circuit. However, it's easier to limit the output power of V_{detect} when using only V_{detect} for detecting, so even short circuit won't damage the devices.

For R_{sense}, we generally select a resistance of a few tens of milliohms. In this way, when the module outputs 48v, it can monitor the current and at the same time consume less power. Because R_{sense} is several orders of magnitude smaller than R_{sig}, we don't take its impact into consideration when calculating the current.

Analysis under symmetric architecture using signature resistance method

We can notice that in standard POE, the architecture of PSE and PD connected through the network cable is asymmetrical. The power supply terminal PSE has no request of receiving power while PD has no request of supplying power. The two devices under POE topology in the project should be symmetrical architecture, which means that either device can be used as a power supply side or a power receiving side. The function of the two devices can change according to the actual situation. Under this architecture, if we use signature resistance detection method, the topology is shown in Fig. 3.

Two identical device structures both have V_{detect} output module and current detection module. The output has parallel signature resistance R_{sig}. Due to the presence of the signature resistance on both devices, V_{detect} output can be detected by current through local R_{sense} whether or not it is connected to a power receiving equipment. The difference is that twisted pair connects through a parallel signature resistor when there is no device connected. So the current is V_{detect} / R_{sig}. When there is a device connected, twisted pair connects through two parallel signature resistors. So the current is $2 \times V_{detect} / R_{sig}$. As a result, we cannot determine the connection by traditional method of detecting whether the current is zero or not. The final decision should be based on the magnitude of the current.

When the power supply outputs 48v, 48v power is applied to two R_{sig}. So it is inevitable that these two resistors have power consumption when applying signature resistance method. If R_{sig} is small, the current detection is simple because of large current flowing through R_{sense} at the expense of greater power consumption. We can reduce the power consumption by increasing the R_{sig}, which reduces the current, but makes it more difficult for detection.

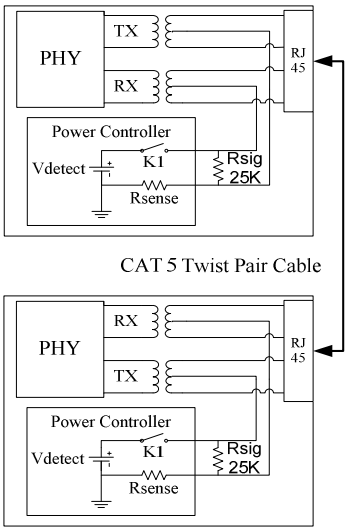

Fig.3 Using signature resistance method under symmetric architecture

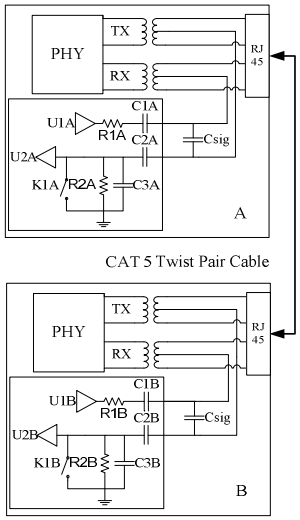

Fig. 4 Another method to detect PD under symmetric architecture

Analysis under symmetric architecture using step response method

We have designed another method to detect PD, which is used for symmetric architecture, as shown in Fig .4. The structures of the two devices are exactly the same. In Fig. 4, R1 is a series current-limiting resistor of 1KΩ, the value of R2 is 20KΩ, C1 and C2 are capacitors of 0.33uF, the value of C3 is 0.47uF, and the signature capacitance C_{sig} is 0.1uF. We assume that device A powers on first and then acts as PSE, device B acts as PD. When PD connects to PSE, PSE does not output 48v to external device, so the influence by PD on the system is only adding a C_{sig} between twisted pairs.

Principles calculation

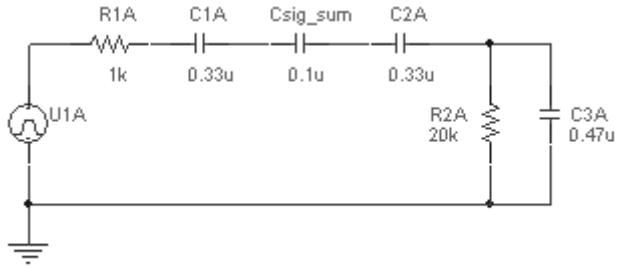

Fig. 5 Equivalent circuit

PSE A first switches on K1A until C3A completely discharges, then it switches off K1A. After K1A is switched off, U1A outputs a step signal. The voltage across C3A can be read via U2A. The equivalent circuit at the moment is shown as Fig. 5.

Whether B is connected with A will influence the value of C_{sig_sum} in Fig. 5. As can be seen in Fig. 4, we can easily find that C_{sig_sum} is 0.1uF when B is disconnected with A. When B is connected with A, C_{sig_sum} is 0.2uF (Because two C_{sig}s parallel connected).

At initial moment, the quantity of charge on C3A is 0 and U1A outputs a step signal. We need to know how the voltage across C3A changes when C3A in nought state is under the influence of step signal. At the beginning time, the voltage output by U1A leaps from 0v to 3.3v, so the influence caused by C1A, C2A, C3A, C_{sig_sum} on the circuit is almost like short circuit. The value of the current at this time is 3.3v/R1A, and this current charges the four capacitors. After a long enough time, the output of U1A is 3.3v, charging and discharging the four capacitors are completed, so the influence caused by C1A, C2A, C3A, C_{sig_sum} on the circuit equals the influence of open circuit, and the voltage across C3A is 0. Under the stimulus of step signal, C3A is first charged by U1A and then discharged through R2A, so the voltage across C3A performs as a waveform which first rises then falls. We analyze the time when the peak appears and the value of the peak in the following paragraphs.

Based on Fig. 5, we list the second order differential equations and substitute the initial conditions of nought state, and then we can get the voltage across C3A U(t) as:

$$U(t) = K_1 e^{-\frac{t}{\tau_1}} + K_2 e^{-\frac{t}{\tau_2}}$$

In this equation, τ_1 is electrical charge time constant. When the step signal appears, current charges the four capacitors through R1A, so we can get:

$$\tau_1 \approx R1A * (C1A // C2A // C3A // C_{sig_sum})$$

τ_2 is electrical discharge time constant. After the four capacitors are completely charged, C3A discharges mainly through R2A, so we can get:

$$\tau_2 \approx R2A * C3A$$

It can be easily seen that whether or not the powered device is connected, that is whether C_{sig_sum} is 0.1uF or 0.2uF, $\tau_1 << \tau_2$ because of $R2A >> R1A$. The electrical charge time constant is much smaller than the electrical discharge time constant, so the voltage across C3A increases first and then decreases. If the powered device is connected, C_{sig_sum} changes from 0.1uF to 0.2uF, but the change of τ_1 is not so large compared with τ_2, so the time when the voltage across C3A rises to peak has almost no change.

Whether or not the powered device is connected will influence the value of C_{sig_sum} (0.1uF or 0.2uF). During the process of charging, C1A, C2A, C3A, C_{sig_sum} are series connected, so it is easy to see that when C_{sig_sum} gets larger, the peak voltage across C3A rises.

Simulation result

A PSPICE simulation is done, and we get the waveforms as shown in Fig. 6 and Fig. 7.

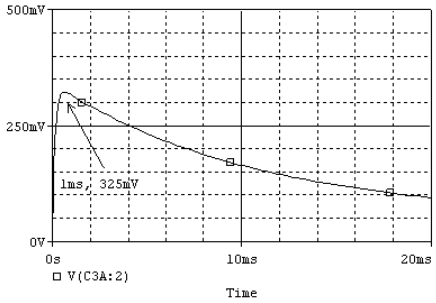

Fig. 6 Simulation waveform when powered device is disconnected

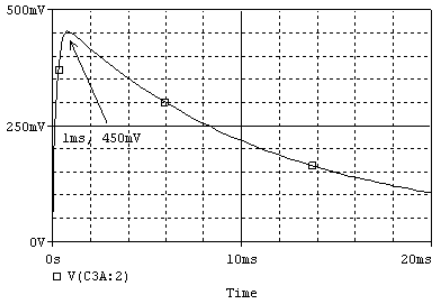

Fig. 7 Simulation waveform when powered device is connected

From Fig. 6 and Fig. 7, we can find the waveforms are consistent with our expectation. For the two cases, the time durations from the beginning to the time when peak appears are almost the same and they are all about 1ms, so we use 1ms as sampling time. However, for the two cases, the wave amplitude difference in the sampling time is obvious. So we can sample the voltage across C3 in 1ms after step signal effecting. By comparing this voltage with threshold voltage, we can know whether the powered device is connected or not.

Experimental results

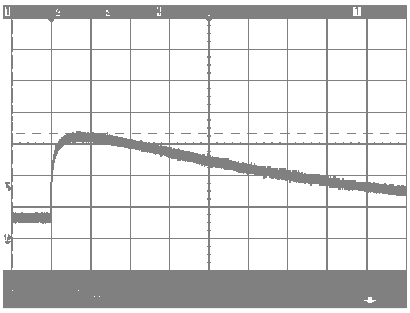

Fig. 8 Measured waveform when powered device is disconnected

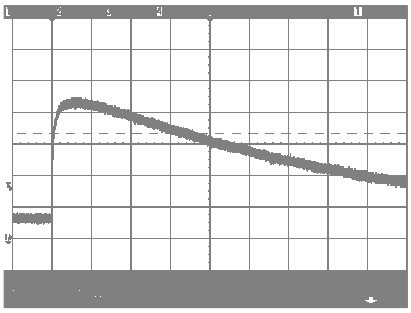

Fig. 9 Measured waveform when powered device is connected

Fig. 8 shows the measured waveform when powered device is disconnected and Fig. 9 shows the measured waveform when powered device is connected. The measured results match well with the simulation results. According to the experimental results, we can sample the voltage across C3 in 1ms after the step signal effecting, and we take the threshold for 400mv. When the voltage across C3 is larger than threshold, we believe that the powered device is connected.

When power sourcing equipment and powered device are connected using long twisted pair, we need to consider the influence of cable capacitance. Cable capacitor parallel connected with C_{sig} makes C_{sig_sum} larger, and then makes the peak voltage of C3 larger as well. So when we use this method in practical applications, revisions are needed for the detection threshold voltage according to the cable length.

Conclusions

When we use Power Over Ethernet technology, in order to ensure security, PSE will definitely detect the connection of powered devices during the working process.

When the device outputs 48v power supply, if using signature resistance method, R_{sig} will certainly consume energy. Static power consumption is about 180mW when 48v power is applied to two parallel 25KΩ resistors. If you select larger R_{sig} to reduce power consumption, it will increase the difficulty of the current detection. However if we use step response method which uses C_{sig} instead of R_{sig}, the static power consumption is zero. It is ideal for the use in low-power design.

Comparing the signature resistance method (Fig. 3) and the step response method(Fig. 4), the former requires a switch to control the excitation signal output, while the latter uses direct capacitive coupling, in which the implementation is relatively simple.

Our project has stringent power requirements, so step response method has been used to detect the connection of the powered devices and the system works well in the project.

Keywords: photovoltaic array; fault diagnosis; BP neural network; network training; Matlab simulation.

Abstract: In consideration of the photovoltaic arrays fault characteristics and the limitations of traditional fault diagnosis methods, a intelligent fault diagnosis system for photovoltaic arrays based on BP neural network is proposed.; The faults' consequences of battery cracking, short circuit and the shadow is analyzed. The neural network is trained by appropriate fault samples. The simulation and experimental research on online fault diagnosis of photovoltaic modules in the Matlab environment are performed，and results proved the accuracy,effectiveness and environmental adaptability of the proposed system.

Introduction

Photovoltaic (PV) power is probably the strongest-growing electricity generating technology because of its advantages of clean ,cheap and reproducible [1-2], photovoltaic power generation's application fields and expanding scale is constantly developing.But Photovoltaic array has some faults inevitably due to the natural environment and the influence of its aging problem in the process.If the fault is not found and eliminated in time, it will directly affect the normal operation of the photovoltaic power generation systems, even burn out the battery components when seriously [3].Therefore the fault diagnosis for photovoltaic system has very important significance to the power system's normal operation.At present the photovoltaic diagnostic methods are mainly:Infrared test [4],Earth capacitance measurement（ECM）[5-6],Time domain reflectometry（TDR）[7]. ECM and TCR need to stop the system when the system is testing;Infrared detection needs a lot of infrared cameras and sensors, increasing the operation cost of the system. This paper proposes a intelligent fault diagnosis system of photovoltaic array based on BP(back propagation) neural network, which can display the corresponding relationship between the photovoltaic array's fault and cause of the fault in the neural network structure,connection weights and threshold. The experiment's data will input into the trained neural network fault diagnosis, so as to realize the online fault diagnosis of PV arrays.

Analysis of PV common faults

Photovoltaic power generation system is hard to avoid some faults for long-term working in the outdoor environment[8-10]. Photovoltaic array's common faults are are shown in table 1.

Table 1. Analysis of PV faults

Fault type	Description	Consequences
Panels aging damage	The fault happens after long time running , Such as short circuit 、 open circuit fault, etc	Produce arc and have fault due to overheat and damage
Panels cracking	When Panels have cracks on the surface, Water and air will corrosion film	Battery life greatly reduced
Shading	Building 、 cloud or objects such as the tree shading	Battery local temperature will be too high

According to current situation,The third type fault is probability maximum damage.Therefore we will discuss the causes and consequences of photovoltaic array's hot spot phenomenon following.

The experiment select a matrix module in a three lines four columns from the photovoltaic array. As shown in figure 1，each row is a set，the voltage is U_1-U_3 and current is I. Assumes that the dotted line in the figure is the shade module，while the second group's output current is still I. The shade part become load，and the current direction is contrary to other modules. At this point the second set's current will be more than I/4.If it continues for a long time the solar panels' temperature will be too high, so that the whole system will not work normally.

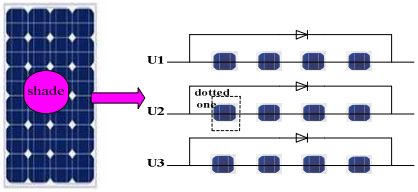

Fig.1 The principle diagram of the PV array hot spot phenomenon

At present,solutions of the phenomenon of hot spots are the bypass diode in parallel and infrared image analysis method basically，but these two methods have their limitations.The parallel diode itself will consume power then cause power loss,and its offset voltage will affect the photovoltaic array's normal work voltage;The infrared image analysis can't realize real-time control and can't estimate when temperature difference is not obvious. The BP neural network intelligent fault system in this paper will make up for the deficiencies of the above methods. The system with strong self-learning, adaptive, contact and nonlinear pattern recognition memory functions and especially suitable for very complex faults.

The application of BP neural network in PV fault diagnosis

The establishment of the BP neural network

Due to the highly nonlinear and strong coupling relationship between the photovoltaic modules'output characteristics and environmental factors,the fault diagnosis of photovoltaic arrays is essentially the input data samples connect with one or more fault state processes.In order to realize the online fault diagnosis of PV array, we introduces the BP neural network as the tool of fault diagnosis which can solve the nonlinear problem effectively [11].

In this paper,the BP neural network composed of input layer,hidden layer and output layer.Each input node corresponding to a fault input,and adjacent layer interconnect with each other.The sam layer neuron without any connection with each other,and input layer and output layer have no direct link .

Now we set up the network's fault input mode as $X=(T_c,I_m,U_m)^T$， the hidden layer's output as $y=(y_1,y_2.y_3)^T$,Build up the mapping relationship between the fault parameters and fault causes. The neural network basic structure is shown in figure 2.While T_c,I_m,U_m as the input signal stand for panel temperature,peak current and peak voltage respectively, y_1,y_2,y_3 corresponding to the various faults in table 1.

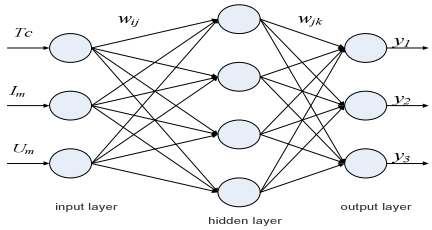

Fig.2 Basic structure of BP neural network

The transfer function of hidden layer adopts hyperbolic tangent tansig function，Now we set the input layer nodes as i（1-3），hidden layer nodes as j（1-4），output layer nodes as k（1-3），.For input layer nodes i，the output of the hidden layer and output layer $y_i(k)$ can be represented as [8-10]：

$$y_i(k) = \frac{e^{I_i(k)} - e^{-I_i(k)}}{e^{I_i(k)} + e^{-I_i(k)}} \tag{1}$$

$I_i(k)$ in the formula (1) is the input signal of node i in the k layer，it usually expressed as output's weighted sum of all node which can be shown as following formula:

$$I_i(k) = \sum_j w_{ij}(k) y_j(k) - \theta_j(k) \tag{2}$$

w_{ij} is node connection weights of the I node in k layer,$y_j(k)$ is output of the j node in the k layer, $\theta_j(k)$ is threshold of the neuron.

Therefore we can realize online fault diagnosis from the output data from the above formula, through extracting the connection weights and thresholds in the trained neural network.

The strategy of BP neural network fault diagnosis

Now establish a system that can fully display monitoring dynamic according to the characteristics of the PV array fault diagnosis, schematic diagram is shown in figure 3.The system is mainly composed of knowledge base, data base,neural network module,panels,interpretation mechanism,translation mechanism,monitoring center. When the fault occurs,it can be quickly located through the knowledge stored in base of diagnosis knowledge，which can help people in monitoring center diagnose and maintain the fault [11-12].

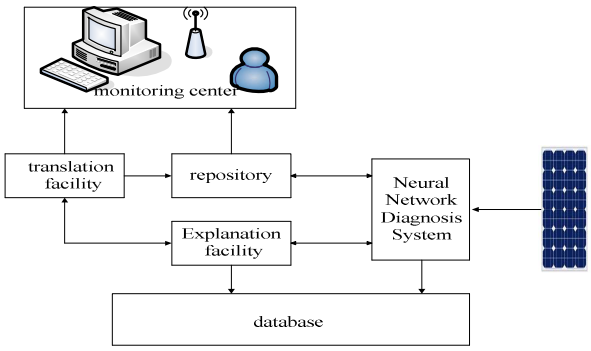

Fig.3 The principle diagram of the BP neural network fault diagnosis

The photovoltaic modules adopted in the experiment is Jiang Su Hosun solar power company's monocrystalline silicon series of JHX100M72.Under the condition of STC(1000W/m2,25℃) the output data is shown in table 2，the panel is made up of 72 series panels.

The experiments adopted increasing the external series resistance value method to simulate the cracking phenomenon,short circuit panels to simulate the phenomenon of short circuit,cardboard block was used to simulate shadow phenomenon.Through the simulation and experiment validation to prove the feasibility of the diagnosis system.

Assuming that solar panels' expected outputs of fault types are:normal（0,0,0）,Panels cracking（1,0,0）,Panels aging and short circuit（0,1,0）,Partial shadow（0,0,1）.

Table 2. PV module parameter

Parameters of the category	Data
maximum power Pm	55W
open-circuit voltage Uoc	21.7V
short-circuit current Isc	3.45A
The voltage of maximum power point Um	17.4V
The current of maximum power point Im	3.15A

The flow chart of neural network fault diagnosis when photovoltaic power generation system is running is shown in Figure 4.To judge whether a fault happens by detecting if the data exceed the normal parameters deviation of solar panels or not,then assess the type of failure,and finally inform people of monitoring center to maintain timely.

BP neural network model training and experimental

In order to verify the validity and the accuracy of the fault diagnosis system，This experiment collect 200 groups sample data of these faults under condition of different temperature, peak voltage, peak current for training network. Neural network training sample run in Matlab environment, training for 1000 times, the training error is 0.001, the training step length is 0.05, using tansig training function.

As shown here, neural network can meet the error requirements after 414 times training. The system has a good learning performance with control precision reaching 0.0009.The results are very accurate.

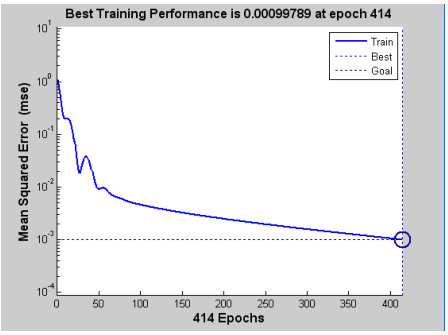

Fig.5 The curve of BP neural network training

After the network training is finished，four group actual measured data will be inputed into diagnosis system to observe its output whether in line with the expected results. The

input data and output results is shown in table 3. As shown in the table，faulty node value is close to 1，non-faulty node value is close to 0，the accuracy reach 90%. The network output and target output has reached preliminary requirements which can prove the feasibility and accuracy of the system.

Table 3. The predictions of the model

T_c/℃	I_m/A	U_m/V	y_1	y_2	y_3
43.21	4.05	24.2	0.000	0.001	0.002
42.95	3.59	18.5	0.968	0.001	0.000
43.15	3.85	22.6	0.001	0.994	0.001
50.12	4.01	23.5	0.001	0.002	0.987

Conclusion

Since the highly nonlinear of the photovoltaic cells , diversity of environmental conditions and various influencing factors making photovoltaic array fault diagnosis become a complex problem。This paper presents a kind of on-line fault diagnosis system based on BP neural network, input factors are battery temperature, maximum power voltage and maximum power current. The system can test four state as normal, cracking, short circuit and shadows. The simulation and experimental results prove the feasibility, accuracy and environmental adaptability of the proposed fault diagnosis system, it has good application prospect.

Keywords: AM-OLED; Stereo Display; Dual Video; Interface Circuit

Abstract. OLED micro-display is applied widely in the HMD stereo display field. Based on dual 0.5 inch 800×600 high resolution AM-OLED displays, we proposed a 3D circuit design scheme which used PC's VGA interface as video input, PIC18LF2550 as the MCU. According to the principle of the human eye binocular disparity, PC stereo video sources achieved odd frames and even frames displaying simultaneous in two AM-OLED panels, which implemented the 3D function. Display system has been tested by playing the stereoscopic video source of the left and right sides format form the PC and the effect presented a good performance which verified the effectiveness of the proposed scheme.

Introduction

With the development of the dimensional technology, the core components of stereoscopic display developed from small CRT to LCD, and then to the current micro AM-OLED. Cause of low power consumption, high refresh rate, wide viewing angle, high contrast, high brightness and other characteristics, OLED is increasingly being applied to the near-eye stereoscopic display system [1]. Foreign stereoscopic display technology is relatively mature, the corresponding products are greater. eMagin developed the world's first 3D capabilities HMD "eMagin Z800 3D Visor" in 2006, this helmet is equipped with dual 0.5 inches 800×600 high resolution OLED micro-display chip [2] ; Sony launched HMZ-T1 head-mounted 3D display with a newly developed 0.7 inches 1280×720 resolution OLED panels in December 2011, which can achieve 20 meters watch 750 inches giant screen of 3D effects ; SMD company released a resolution of 1920×1080 Full HD 3D HMD ST1080 in January 2012, its headset weighs only 180 grams [3]. Some domestic universities are mainly on the helmet stereo display with more research. Southeast University designed and implemented a resolution of 1024×768, refresh rate of 180Hz sub-field of LCOS color helmet display, which is enable real-time color video image display; Beijing Institute of Technology Cheng Dewen, Wang Yongtian et al, whose used FFS prism new optical components, the new aberration theory and design optimization methods HMD visual optical system to optimize the design, the optical design can satisfy the system view and make its weight reduce greatly structure more compact at the same time [4]. This paper used dual VGA interface as the video input interface, AM-OLED as stereoscopic display panels, based on binocular parallax principle of the human eye and SVGA050 micro chip stereo display function, and definitively realize stereoscopic display through the computer graphics frame display technology. Our design is two-way video signals imaged in both eyes, which significantly reduces crosstalk between the eyes, provide the best stereo effect by adjusting the distance and the position between the dual AM-OLED and optical system.

Stereoscopic Display System Interface Circuit Design

Based on the structure and characteristics of the AM-OLED, the design of hardware interface circuit is shown in Fig.1. VGA Decoder module decodes external input for VGA video signal by using the AD's chip AD9883; MCU used the production of Microchip's high-performance, low-power control chip PIC18LF2550, mainly used for A/D and display module configuration register; power modules provided an external 5V power conversion by USB, respectively produce

3.3V, 5V, 1.8V power supply provides power for the various modules[5]; OLED used OLEiD Company's new high-resolution ,active 0.5 inches AM-OLED display module SVGA050. For a good solution to the product weight and wearing comfort, our system is divided into two parts: master-board and OLED panels. Each OLED panel retains only the display chip and A/D decoder; all other devices are designed on the master-board. Whole system consists of a master (80×80mm) and two OLED panels (40×40mm). Two OLED panels via a connector join to the master-board, which transmitting the video source, power supply and IIC (Inter IC Bus) control signals to the A/D and OLED chips. The following introduced the master-board and the OLED panel functions.

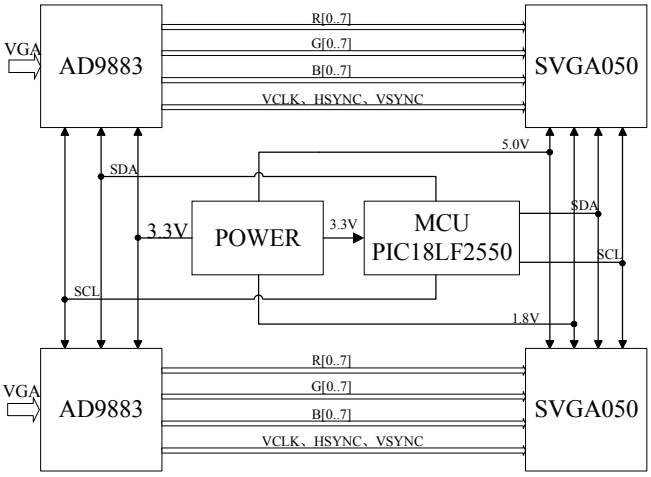

Fig.1 AM-OLED stereo video display system

Master-board Design

The master-board consists of MCU controller and power module. MCU used Microchip's low-power mainstream production control chip PIC18LF2550, the MCU is only 5.8μA in idle state consumes, even its power consumption is as low as 1.8μA in a low- power sleep state[6], Master Synchronous Serial Port module supports 3-wire SPI and IIC master-slave mode, this eliminates the use of general analog IO IIC bus inconvenience for programming provides a convenient. Its main role is set the AM-OLED display and AD9883 registers parameters through the IIC bus[7]. Through the control buttons on the system panel, you can adjust the display mode of the system, including switching OLED internal test pattern and selecting a different video sources as well as brightness, contrast adjustment. The system includes MODE, UP, DOWN three function keys, which MODE is the mode selection keys to cycle four kinds, such as functions brightness, contrast, display pattern, the input source; UP and DOWN for the upper and lower adjustment key, you can adjust specific parameters in different modes.

OLED Panel Design

OLED panels consists high-resolution, active 0.5 inches AM-OLED and AD9883. This system used SVGA050 is produced by OLEiD's latest development of active, high-resolution digital OLED micro-display chip. Fig. 2 shows the block diagram of the OLED panel, gives a signal interface micro-display chip, R, G, B video signals for the three input terminals, HS, VS, respectively horizontal sync and vertical sync signals, P_SDA, P_SCL were IIC serial bus data input and clock input. As can be seen from the figure, the user just need to give the micro-display chip to provide power, and through the IIC bus on the rational allocation of internal registers can be externally input analog video signal on the OLED panel display correctly.

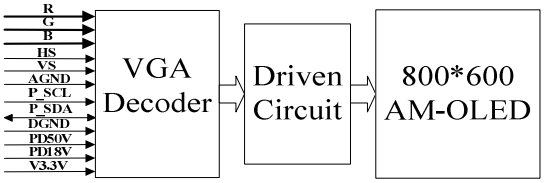

Fig.2 OLED panel structure diagram

Since VGA interface output is an analog signal, you need an analog to digital converter chip to decode the signal. The system chosen the AD decoder chip produced by a A/D conversion chip AD9883, capable graphics card on the PC analog RGB signal output speed 8-bit A/D conversion [8].

Power Modules Design

In this system, it is required to provide power modules are mainly Decoder AD9883 (3.3V) in VGA Decoder Module, PIC18LF2550 (3.3V) in MCU control module, SVGA050 micro-display chip (1.8V and 5.0V Dual) in the display module, and the USB input power is supplied 500mA 5V power, so the design chosen two DC-DC module voltage of 5V and 3.3V respectively convert 1.8V, respectively, as the AD9883, MCU, SVGA050 power. Meanwhile, in order to reduce power consumption and extend the service life, SVGA050 did not require work when the power is disconnected, so the design selected specially enable control terminal with DC-DC module, when it does not operate in a long time, the MCU can be cut off SVGA050 power supply.

IIC Module Registers Configuration

In this system, each module MCU register configuration is achieved through the IIC bus. For the IIC, only two bus lines: a serial data line (SDA) and a serial clock line (SCL). Obviously, OLED is a receiver. Display Address (Slave Addr) can be selected via SelAdr0 pin. Default SelAdr0 through an internal 10K resistor is pulled high (1.8V). Binocular application, which will be a display SelAdr0, grounded. Corresponding to the display read / writes address shown in Table 1. In this system, using the resolution is SVGA 800×600, field frequency is 60Hz, the line frequency is 37.9KHz, point frequency is 40MHz. AD9883 sampling clock by configuring the phase-locked loop (PLL) to generate, using the horizontal sync signal (HSYNC) as the reference clock, then frequency obtained by A / D converter sampling clock required. By decoding chip AD9883 internal 25 register settings, you can achieve the corresponding functions.

TABLE 1 SLAVE ADDRESS AND SELADR0 CONFIGURATION LIST

A7 (MSB)	A6	A5	A4	A3	A2	A1 (SelAdr0)	A0 (R/W)	Slave Addr (R/W)
0	0	0	1	1	1	0	1/0	1DH/1CH
0	0	0	1	1	1	1(default)	1/0	1FH/1EH

Dimensional Display Function Is Implemented

The three-dimensional display scheme based on the human visual design principles of binocular parallax. Binocular disparity is due to two positions in space and different perspectives of the same scene is formed on the retina of both eyes are very similar but slightly different images, which inconsistencies binocular retinal image [9]. The main advantage of the existing three-dimensional display of all of the human eye binocular parallax .As is shown in Table1, SVGA050 with 3D video display capability. SVGA050 display in progressive scan mode, 3D video signals using the frame sequential patterns, such as updating the left eye shows odd frames, even frames update right eye display. In interlaced mode, 3D video signal using a field sequential mode, as left-eye display updates the odd field, even field update right-eye display. Frame sequential or field sequential 3D video display through the 3D signal pin and SVGA050 display 02H register with the realization, 02H register the main function is to set the 3D features. As shown in Table 2, when the 3D pin 02H register 3D set level and consistent, SVGA050 valid input video signal data, the display is updated to the current input frame field data, otherwise, the data is invalid, the display to maintain a frame field data .In this system, OLED in the progressive scan mode, 3D video signal using the frame sequential output mode as the odd frame update left-eye display, even right-eye display frame update.

TABLE 2 3D FUNCTION CONTROL

3D pin	3D refresh	02H	Pattern	Display
0	X	X	2D	refresh
1	0	0	3D	refresh
		1		Keep the last show
	1	0		Keep the last show
		1		refresh

In order to achieve three-dimensional display requirements, according to binocular parallax, the monitor needs to use a 3D display function SVGA050 achieve stereoscopic display video source. SVGA050 display in progressive scan mode, 3D video signals using the frame sequential mode; in interlaced mode, 3D video signals using field sequential mode. Frame sequential or field sequential 3D video display through the 3D signal pin and SVGA050 02H register with the realization of the display, as shown in Table 2,02H register is used to set the 3D video display format, including 3D and 3D enabled refresh. When the 3D pin level status and 02H register 3D settings consistent, SVGA050 valid video signal data input, the display is updated to the current input frame field data, if inconsistent, displayed on a display to maintain field data. 3D pin signals the presence of synchronous edge is locked. 3D shows the timing diagram shown in Fig.3.

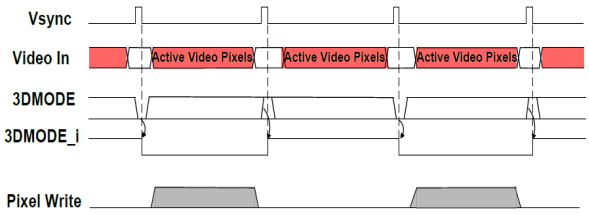

Fig.3 3D video display timing

Experimental Testing and Analysis

Fig.4 shows a stereoscopic video display system physical map. Binocular stereoscopic display system requires achieve a clear near-eye display when video via optical amplification system. In order to verify the feasibility of the program, we have designed an experimental platform. PC's VGA port via VGA converter convert dual VGA video signal to input master. PC's setup parameters are: screen resolution of 800×600, a refresh rate of 120Hz. Though the PC, so the format stereoscopic video source via the Stereoscopic Player playback software playback around two OLED panel displays the video source, respectively, odd and even-numbered frame image frame, and ultimately to achieve a 3D display.

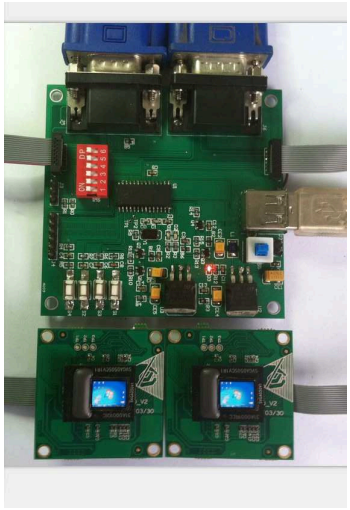

Fig.4 AM-OLED stereo video display system

Conclusions

Based on the 0.5-inch SVGA050 AM-OLED micro-display, we have designed and developed a set of stereoscopic display interface circuitry in this work. USB port provides 5V DC as the only input power, PC's VGA as the input video source, the parameters of each module registers are under control of the MCU (PIC18LF2550) through the IIC serial bus. According to the principle of the human eye binocular disparity, PC stereo video sources achieved odd frames and even frames

displaying simultaneous in two AM-OLED panels, which implemented the 3D function. This hardware design operated simply and low power consumption, which has a high practical value in the civilian HMD system and provide an experimental platform for the 3D visual characteristics of human eyes subsequent research.

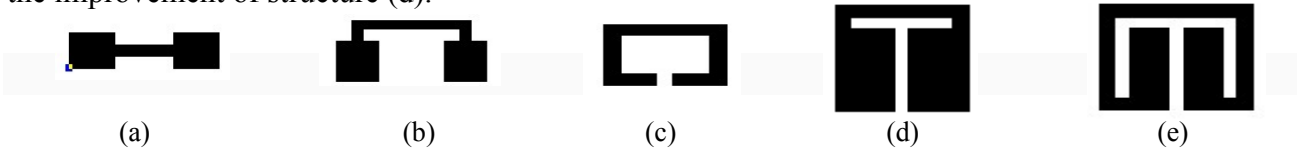
Keywords: Wide-stopband; HTS; bandpass filter; Stepped impedance comb line; insertion loss



Abstract: This paper presents the design of a wide-stopband HTS bandpass filter(BPF). The 9-pole wide-stopband BPF has a center frequency 2.21GHz and bandwidth 100 MHz. Based on the step impedance resonator，this filter increase the harmonic frequency to more than 3 times of fundamental frequency. Optimization simulation results shows that insertion loss is less than 0.3 dB in the passband，and stopband suppression is greater than 80 dB within 0~f0-BW and greater than 60 db within the f0 + BW ~ 3 f0. Within the passband, dB (S (2, 1)) < -20. This design not only achieved a good wide stopband and solved the interference problem but also had a simple structure which is easy to implement.

Introduction

With the development of communication technology and the improvement of spectrum utilization, solving the interference problem is a major problem in today's communication. In order to inhibit harmonics and unwanted signals the wide stopband filter is essential[1,2]. Because of high temperature superconducting material has a very low microwave surface resistance, high temperature superconducting filter made of high temperature superconducting thin film has higher Q value and lower insertion loss than filter using conventional materials. HTS filter can effectively reduce the noise coefficient of the receiver system, and improve the sensitivity, and enhance its inhibition of jamming signal, etc. [3]. In this paper, a wide stopband HTS band-pass filter using stepped impedance comb line resonator structures[4] was designed. This filter has small insertion loss and good frequency selection characteristic, and parasitic passband can be moved to 3 times above of the center frequency. In addition, this filter meet the requirement of wide stop-band with a compact structure.

The Design Principle

In a microwave integrated circuit, a variety of resonator can be used in filter, but commonly used is the half-wavelength SIR type [5]. Several typical half wavelength SIR resonators structure are shown in figure 1. Structure (a), (b), (c) respectively on the geometric shape are called linear, u-shaped (pin) and ring. Structure (d) and (b) have similar u-shaped structure, and (d) has the internal coupling. Structure (d) use their open terminal to achieve miniaturization. Structure (e) is the improvement of structure (d).

(a) (b) (c) (d) (e)

Fig.1 Several typical half wavelength SIR resonators

In combination with the actual requirement of high performance (wide stopband, strong outside-band restraint and low insertion loss, etc)receiver, a wide stopband HTS band-pass filter was designed. Structure of resonator was shown in figure 1 (e) (stepped impedance comb line). As shown in figure 2, the LC equivalent circuit model of (e) is composed of long transmission lines and symmetric coupled line [6]. Capacitance Cg can extend certain stopband bandwidth, so filter can achieve certain wide stopband based on this structure.

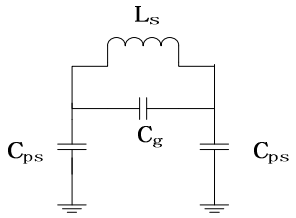


Fig. 2 The equivalent circuit of step impedance comb line resonator

There are many ways to design the filter but the commonly used are CAD method and synthetic method. Because of the CAD method is suitable for the simpler resonator structure or few grade filter, synthetic method is used to design the filter in this paper. Synthesis is use low-pass filter prototype (such as butterworth, chebyshev, or elliptic function) though frequency conversion to synthesize the coupling matrix and the external quality factor of filter based on the theory of coupling. Then through the deep optimization and simulation ,we can design the requirements filter.

Coupling theory of the resonator is very important in the filter design. The key of designing a filter using synthesis method is to derived coupling matrix of filter. After knowing the coupling matrix (internal coupling) and external quality factor (external coupling) of filter, initial value of the filter can be obtained.

The Design of fiLter

This wide stopband HTS filter use sided YBCO / MGO / YBCO high-temperature superconducting thin films. Designed structural parameters are shown as follows:

Permittivity:9.8 Substrate thickness:0.5mm

Conductor conductivity: 4.9e+12 Loss tangent: 1×10^{-5}

This BPF use nine-pole Chebyshev low-pass filter[7] prototype which has 0.01dB ripple. Through look-up the table, we can get the initial value of each element [8]:

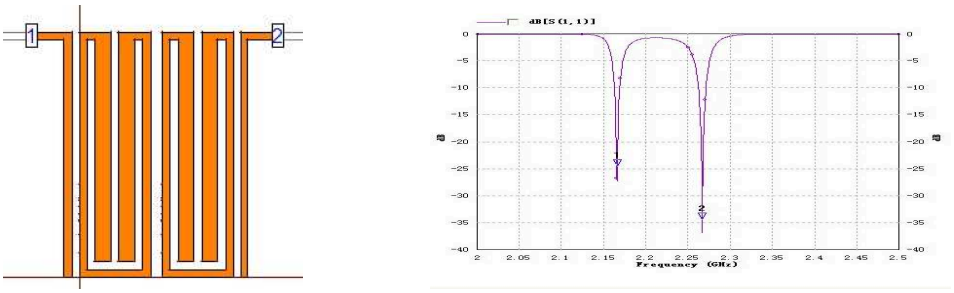
g_0=1.0000，g_1=0.8144，g_2=1.4270，g_3=1.8043，g_4=1.7125，g_5=1.9057，g_6=1.7125，g_7=1.8043，g_8=0.4270，g_9=0.8144，g_{10}=1.0000。

Get these values into the equation of the external quality factor Qe and normalized coupling coefficient $k_{i,\,i+1}$. [8-10]

$$Q_{ei} = \frac{g_0 g_1}{BW} \tag{1}$$

$$Q_{eo} = \frac{g_9 g_{10}}{BW} \tag{2}$$

$$k_{i,i+1} = \frac{BW}{\sqrt{g_i g_{i+1}}} \tag{3}$$



Here, BW = (w2-w1) / w0. By the equation (1) and (2) the external quality factor of the filter can be calculated , i.e. Qei = Qeo = 18.02. By the equation (3) the coupling coefficient between the

resonators at all levels can be calculated, the results are shown in Table 1. Get the external quality factor Qe and the filter center frequency f0 into the equation of the external quality factor $Q_e \approx f_0/\Delta f_{\pm 90^o}$, then obtain ±90º relative phase Bandwidth $\Delta f_{\pm 90^o}$=122.8MHz.

Table 1. Coupling coefficient of the nine grade filter

resonator	1,2	2,3	3,4	4,5	5,6	6,7	7,8	8,9
coupling coefficient	0.0419	0.0282	0.0257	0.025	0.025	0.0257	0.0282	0.0419
slit width [mm]	0.3394	0.5038	0.5382	0.5481	0.5481	0.5382	0.5038	0.3394

Using full-wave electromagnetic simulation software IE3D simulate two-pole resonator structure as shown in Fig 3 (a), then we can get two separated frequencies f_1, f_2 as shown in Fig 3 (b).

(a)The topological structure (b)The simulation results

Fig. 3 Coupling coefficient of the simulation

Corresponding coupling coefficient can be expressed as

$$k = \frac{f_1^2 - f_2^2}{f_1^2 + f_2^2} \quad (4)$$

Depending on the topology shown in Figure 3, we can change the slit width between two resonators as shown in Table 2 in turn, through a plurality of simulations, then can get the resonance frequency of different slit width s (unit: mm). As shown in Table 2, we can calculate the corresponding coupling coefficient k by formula (4).

Table 2. The simulation results of coupling coefficient

s [mm]	0.1	0.15	0.2	0.25	0.3	0.35	0.4	0.45	0.5
f_1 [GHz]	2.12848	2.14087	2.15093	2.15944	2.16641	2.17195	2.17647	2.18111	2.18421
f_2 [GHz]	2.30031	2.28947	2.28096	2.27322	2.26703	2.26169	2.25697	2.25232	2.24845
k	0.0775	0.0670	0.0586	0.0513	0.0454	0.0405	0.0363	0.0321	0.029

Curve between the slit width and the coupling coefficient was shown in Figure 4. The horizontal axis represents the coupling slit width, the vertical axis represents the coupling coefficient. Through the curve, the coupling slit width s of nine-pole filter corresponded by coupling coefficient k can be get. Then initial value of coupling slit width of HTS band-pass filter can be get, as shown in table 1.

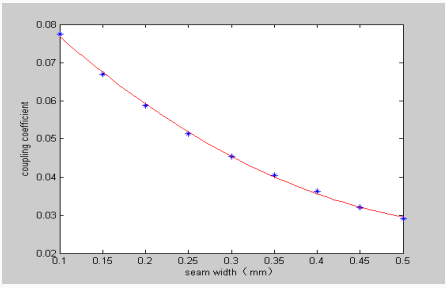


Fig.4 Fitting curve of the coupling coefficient and the seam width

The position relationship between the resonators determines the internal coupling of filter, but energy can not be delivered by the way which only has internal coupling. So appropriate external coupling is needed to get the best response of the filter. If Qe is known, according to the relationship between phase and frequency of S11, the tap position of the input and output of filter can be determined. It is important to note that in some cases the phase of S11 at the resonant frequency is not 0 but there are certain deviation. In this case, we should determine $\Delta f_{\pm 90}{}^{o}$[10] based on the offset point.Simulate the resonator, adjust the tap position,to make $\Delta f_{\pm 90}{}^{o}$ =122.8MHz. The tap distance from the bottom edge is 1.45 mm. As shown in Fig 5.

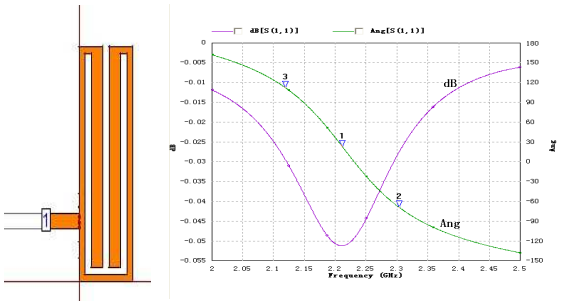

Fig. 5 Tap position simulation

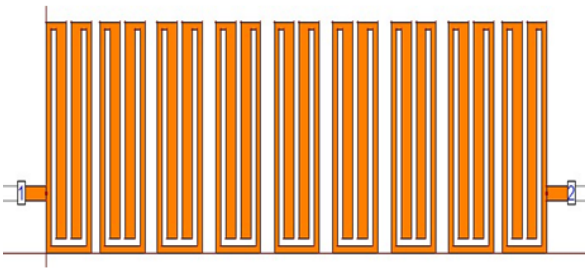

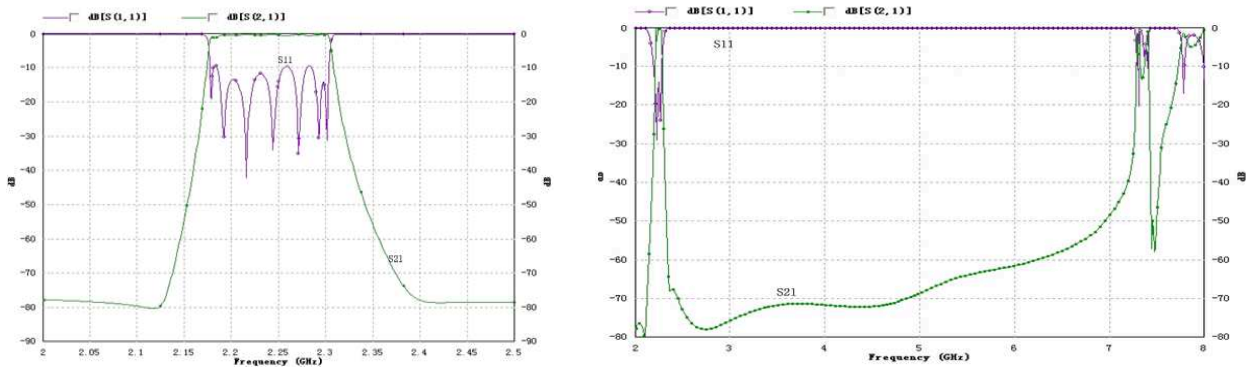

Fig.6 Topological structure

Simulation and Optimization of the Whole Filter Circuit

According to the tap position and Coupling slit width showing above, topology of nine-pole wide stopband HTS bandpass filter can be get. As shown in Figure 6. According to the topological structure of the figure 6, the passband and stopband simulation results are shown in figure 7.

(a)simulation results of passband (b)simulation results of stopband

Fig.7 The simulation results of filter

As shown in figure 7(b), the parasitic passband is moved to more than 3 times of the center frequency . Out-band rejection is greater than 70dB Within 0 ~ f0-BW and greater than 60dB within f0 + BW ~ 3 f0. As shown in figure 7(a), the frequency bandwidth of this broad stop-band filter is consistent with the design goals, but the inband reflection S11 is about -10dB having some gap with an ideal inband reflection (less than-20dB) , so further optimization of the filter is needed.

Because of taking approximate of the formulas and rounding in calculations caused inaccurate results further adjustments to the filter is needed. Adjusted by hand can be used, but debugging is difficult and should take a long time in the case of having too many grades. A feasible method is using the powerful computing ability of computer and the optimization function of IE3D software to optimize the filter.

Set the length of the resonator and the slit width between resonator and tap position as optimization variables, set up a appropriate scope of variables. Fine tune the topology of the filter

showing in figure 6 to reduce reflection coefficient S11. The results after optimization are shown in figure 8.

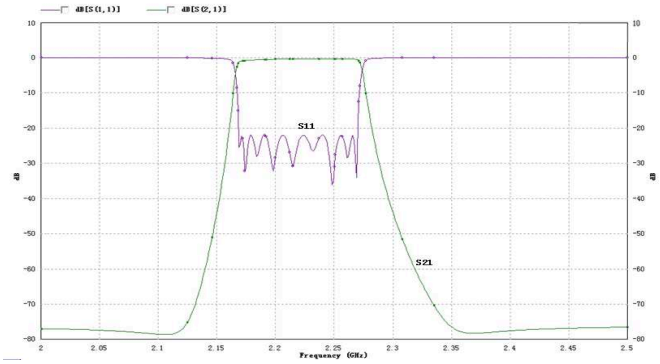

Fig. 8 Optimization results

As shown in optimization results, passband bandwidth of the filter is about 0.1GHz, the center frequency is 2.21GHz (s band), passband reflection S11 is less than-20dB, insertion loss is less than 0.3dB. Filter performance is ideal by achieving a low insertion loss and wide stopband result.

Conclusion

In this paper, wide stopband HTS bandpass filter is researched and designed. Choose stepped impedance comb line resonator and the synthetic method to design the filter. According to the low-pass filter prototype and coupling theory comprehense coupling coefficient and the external quality factor of filter. Then using optimization function of IE3D software to get good results. Using this method can reduce the design complexity and shorten the design cycle. In addition, this paper provided some reference for microwave workers in the actual work.

Key words:RFID; reader antenna; miniaturization;circularly polarization; ultra high frequency; slit in the path

Abstract: A compact and circular polarized antenna for UHF band RFID handset reader was designed, and realized by cutting slits in the antenna patch and etching slots on the ground. Numerical simulation was performed for the characteristics of the antenna with the software HFSS 13.0.The simulation results show that when the size of antenna patch is 68mm×68mm, -10dB return loss impedance bandwidth is 49MHz,VSWR is less than 2 and the largest gain is -0.61dB for antenna in 907～931MHz. Compared with the traditional reader antenna with the same material of the substrate，the improved antenna has a much higher gain．and the size was reduced by 20% and the max gain is raised -0.11dB.

Introduction

Radio Frequency Identification (RFID) technology is a kind of using Radio Frequency communication to realize the non-contact automatic identification technology. In recent years, RFID has entered the stage of commercial application, such as large scale integrated circuit, network communication and information security[1]. The RFID system is consisted by the reader, reader antenna and tag.The reader sends continuous wave (CW) signal to the tag to activate its microchip and then commands that are modulated to the signal.The tag responds its identification code using backscattering of modulated electromagnetic wave.Circularly polarized antennas are widely adopted in RFID communications to ensure the reliability of communications between readers and tags[2],and this makes it convenient to read the label information.

In China, RFID system assigned frequency band 840 ~ 845MHz and 920 ~ 925MHz for RFID band. With the rapid development of RFID,designed a reader antenna which is suitable for Chinese UHF RFID system having an important significance to promote RFID application.Traditional forms antennas for handheld RFID reader is too large,while On the premise of keep the antenna performance,reduction the reader antenna size is more difficulty than reduction reader circuit. Therefore,the size of the antenna miniaturization has become the current trend of the RFID reader antenna research[3]-[5]. In this paper , We designed a new type of small antennas in order to improve the size and performance of the domestic reader antenna.

Antenna design

In order to realize the miniaturization of reader, it is necessary to design special miniaturization of microstrip antenna[6].According to the theory of microstrip antenna, we can achieve the purpose by improved the dielectric substrate`s relative dielectric constant, loaded the short circuit probe and slotted or slit in the radiation patch or other methods to reduce the size of the patch antenna.Slots

and slits` essence is by extending the microstrip antenna radiation patch`s excitation current on the surface, it`s Equivalent to prolong the equivalent current path to achieve the goal of reducing the antenna size. Based on the concept,designed a circularly polarized reader antenna which is suitable for handheld RFID reader working in 920MHz.

By transmission line theory, according to the working frequency, we can calculate the radiation patch antenna size By (1) - (4) :

$$W = \frac{c}{2f}\left(\frac{\varepsilon_r + 1}{2}\right)^{-1/2} \quad (1)$$

$$L = \frac{c}{2f\sqrt{\varepsilon_e}} - 2\Delta l \quad (2)$$

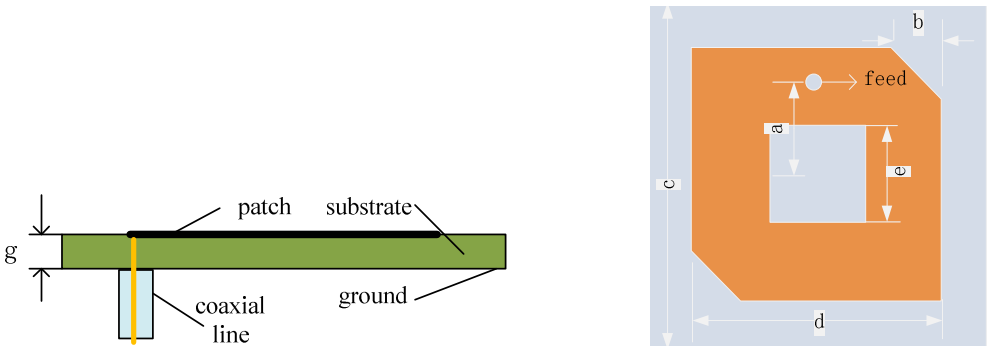
$$\varepsilon_e = \frac{\varepsilon_r + 1}{2} + \frac{\varepsilon_r - 1}{2}\left(1 + \frac{10h}{W}\right)^{-1/2} \quad (3)$$

$$\Delta l = 0.412h\frac{(\varepsilon_e + 0.3)(W/h + 0.264)}{(\varepsilon_e - 0.258)(W/h + 0.8)} \quad (4)$$

In formula : W and L are the the radiation patch`s width and length respectively; ε_e is the effective relative dielectric constant; Δl is equivalent radiation slits length; W have some effects on band width, input impedance and radiation efficiency, when elect a width greater than the above formula, the antenna's radiation efficiency become higher, so prone to distortion caused by the high-order mode field.

This article takes the form of a square patch antenna, so we choose W = L.Theoretically,the floor can be considered infinite, but in practical engineering design, taking into account many factors such as antenna installation size,quality and cost ,the floor size should be as small as possible. When the floor satisfied the formula $W_0 \geq W + 0.2\lambda_g$,the floor can be regarded as infinite[7].

In order to realize the miniaturization design of antenna,we Can change the microstrip patch antenna surface current path to achieve. In Literature[8], low cost FR-4 material is choose as the substrate,by cutting the triangle Angle on the patch to realize circular polarization and Opening square groove in the center of the patch to achieve miniaturization. Fig.1 shows the geometry of the proposed circularly polarized antenna.



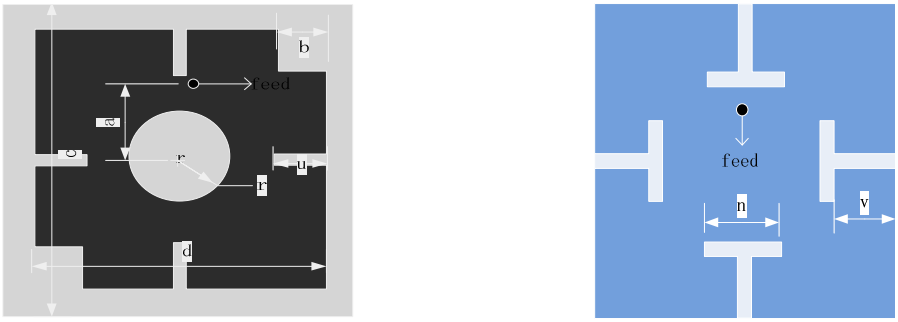


Fig.1 Side view and vertical view of the antenna

This antenna consists of three parts:the upper surface is d×d of square patch which is digging square holes and cutting triangle Angle on it,the middle is the substrate and the lower surface of the substrate is a c×c square floor. When the antenna size is 90mm × 90mm × 3mm, the antenna return loss and axial ratio bandwidth is covered China UHF RFID band 920 ~ 925MHz and the antenna gain is -1dB.

The author made some improvements based on consulting a large number of literature.A square side length b was chosen instead of cutting triangle which could help to increase bandwidth of the antenna;Open a circular hole in the middle,the length and the width of the slits were chosen as u and 1.5mm respectively. It will affect antenna`s size and resonant frequency.At the same time, open a "T" shape On the floor,the length is n and v, slits width is 1.5 mm .

The improved antenna is shown in fig.2:

(a) (b)

Fig.2 A side view (a)of the improved antenna and the front and back structure(b)

Simulation And Experimental Results

Ansoft High Frequency Structure Simulator (HFSS) was used to simulate and optimize the parameters of the proposed antenna.As can be seen from Fig.3, with the slits is deeper on the antenna patch ,the chip area become smaller ,the resonant frequency is decreases,The bandwidth of the antenna become narrow,Therefore increase the depth of slits blindly would cause sacrifice the bandwidth of the antenna.

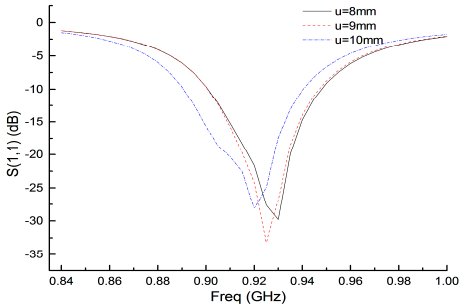

Fig.3 Effects of changing U on S11

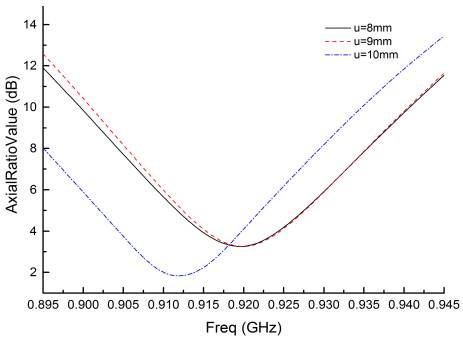

Fig.4 Change trends of antenna axial ratios with u

Fig.4 is the antenna axial ratio changed with u,from Fig.4 can see that axial ratio and the slits depth is irregular changing. When the slits length is increase the resonance frequency decreases .

The return loss and the axial ratio with the change of square cutting angle are shown in Fig.5 and Fig.6.As can be seen from Figure 5,when the length b increase,the S11 curve moves to the right. With the resonance frequency increases gradually , the bandwidth of the antenna becomes larger than before.But when the cutting angle size was chosen as 8mm,the return loss has a certain convex and it Shows that S11 index is deterioration.Thus curve analysis shows that within a certain

range,the patch`s cutting angle can not only produce circularly polarized but also be used to adjust the antenna bandwidth.

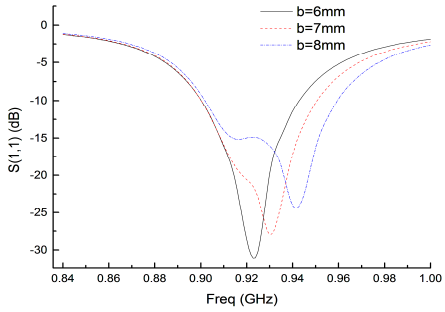

Fig.5 Effects of changing square cutaway b on

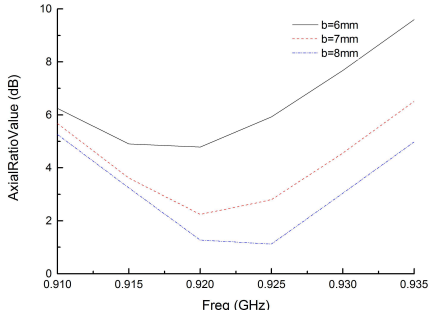

Fig.6 Changing trends of antenna axial ratios with b

simulate and optimize the parameters of the proposed antenna:when u=8.4mm,b=6.6mm,v=15.5mm,k=7.5mm,n=6.4mm,antenna performance is the best.Its return loss shown in Fig.7. Fig.7 shows the -10dB bandwidth is 45MHz (900~945MHz), and it covers the required bandwidth (920~925MHz).

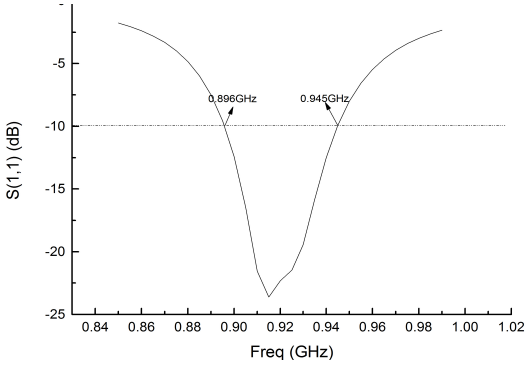

Fig.7 Graph of microstrip antenna return loss

Fig.8 and Fig.9 are the antenna radiation pattern.It can be seen that the antenna has good radiation performance.Compared with the traditional reader antenna ,the peak antenna gain is -0.61 dB at 920MHz and the size reduced by 20% accordingly.

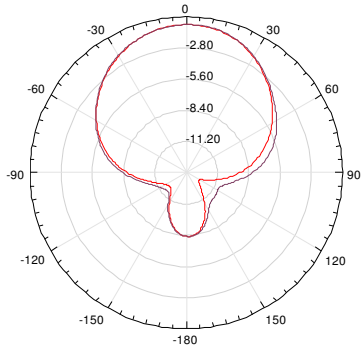

Fig.8 Planar antenna radiation pattern

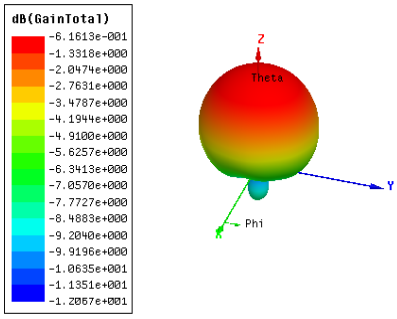

Fig.9 3D antenna radiation pattern

Fig.10 shows simulated axial ratio in the broadside of the antenna. The simulated 3 dB axial ratio bandwidth is about 12MHz from 914MHz to 926MHz around the center frequency 920MHz which reaches the requirement of the UHF RFID reader antenna.

The higher VSWR,the higher reflected power and the lower transmission efficiency. In the bandwidth of 907 ~ 931MHz simulated VSWR is less than 2 and in 920MHz VSWR = 1.3 indicates that the antenna has a good matching .

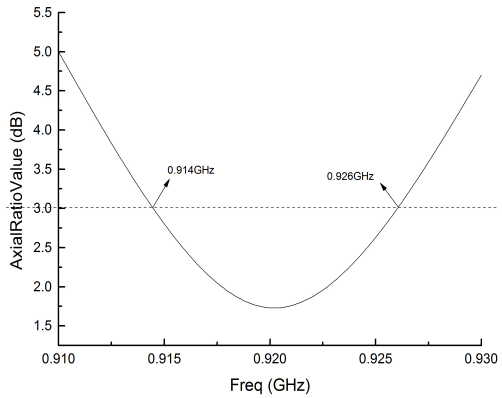

Fig.10 Antenna axial ratio changes graph

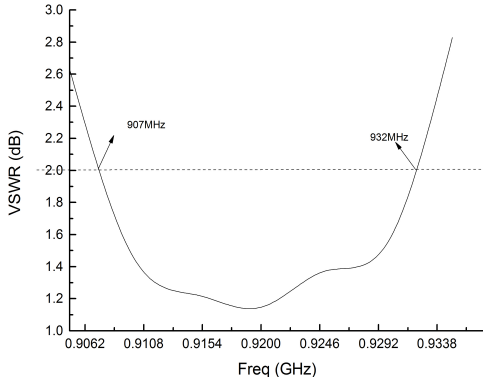

Fig.11 Antenna VSWR curve graph

Conclusion

This paper presents a read range performance study of compact reader antennas for a handheld UHF RFID reader.A novel design of circularly polarized RFID reader antenna with cutting slits in the antenna patch and opening round hole on the radiation patch to reduce the physical size;Through the square cutting angle to realize circular polarization;Through etching slots on the floor to improve antenna gain.Based on the above principles to design a handheld reader antenna which is suitable for china to use in UHF RFID band.The simulation optimization shows that antenna main performance index in volume, VSWR, bandwidth, gain and circularly polarized all satisfies the requirement of handheld RFID reader antenna.

An Effective Model for Wire Medium Based on the 4th Order Dispersion Equation

Zhun Yang, Wei Song [a] and Xin-Qing Sheng

School of Information and Electronics, Beijing Institute of Technology, 100081, China

[a]wsong@bit.edu.cn

Keywords: wire medium; 4th order dispersion equation; effective model.

Abstract: In this paper, the wire medium made of parallel thin wires is studied by using the FDTD method incorporating the sub-cell technique of thin wire. The conventional effective model for the wire medium is based on the 2th order dispersion equation; and it becomes inaccurate for EM behavior calculation of wire medium when the transversal spatial harmonics becomes high. A new effective model is proposed based on the 4th order dispersion equations and surface fitting, which guarantees the modeling accuracy for higher spatial harmonics.

Introduction

Wire medium (Fig. 1) is a type of periodic structure consisting of parallel metallic wire array with interesting EM properties and applications. It enables the realization of sub-wavelength imaging with literarily no limit of resolution [1,2]. This is verified both numerically [3,4] and experimentally [2,5]. In [6], the exact dispersion equation of the ideally conducting thin wire array is deduced under the only assumption that the radii of wires are much smaller than the lattice periods and the wavelength, and it can be written as follows:

$$\frac{1}{\pi}\ln\frac{b}{2\pi r}+\frac{1}{bp_y^{(0)}}\frac{\sin p_y^{(0)}a}{\cos p_y^{(0)}a-\cos q_y a}+\sum_{n\neq 0}\left(\frac{1}{bp_y^{(n)}}\frac{\sin p_y^{(n)}a}{\cos p_y^{(n)}a-\cos q_y a}-\frac{1}{2\pi|n|}\right)=0, \tag{1}$$

where $\mathbf{q}=(q_x,q_y,q_z)^T$ denotes the wave vector of an extraordinary mode. Parameters *a* and *b* denote the lattice periods in the y- and z-directions respectively, and *r* denotes the radius of the wire, as shown in Fig.1. $p_y^{(0)}$ is the y component of the n^{th} Floquet mode wave vector:

$$p_y^{(n)}=-j\sqrt{\left(q_z+\frac{2\pi n}{b}\right)^2+q_x^2-k^2},\quad \mathrm{Re}\left\{\sqrt{()}\right\}>0, \tag{2}$$

where $k=\omega\sqrt{\varepsilon_0\mu_0}$ denotes the wave number in the free space.

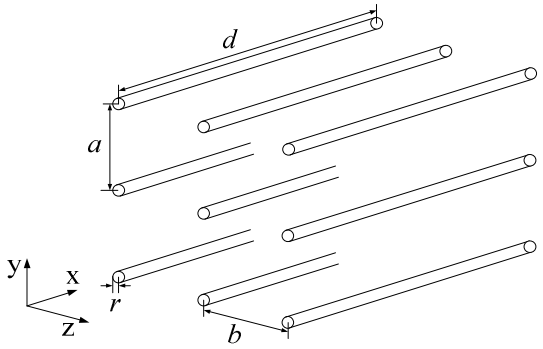

Fig. 1. The wire medium formed by an array of thin wires periodically arranged in rectangular lattice.

From Eq. 1 and Eq. 2, an approximated dispersion equation can be obtained by using the second-order Taylor expansion of sine and cosine functions of small arguments:

$$q_x^2 + q_y^2 + q_z^2 = k^2 - k_p^2 . \tag{3}$$

Based on Eq. 3, a uniaxial effective model was proposed to characterize the wire medium under a further assumption of $a, b << \lambda$ [7],

$$\overline{\overline{\varepsilon}} = \varepsilon\left(k, q_x\right)\mathbf{xx} + \mathbf{yy} + \mathbf{zz} \quad , \quad \varepsilon\left(k, q_x\right) = \varepsilon_0\left(1 - \frac{k_p^2}{k^2 - q_x^2}\right) , \tag{4}$$

where the notation k_p plays the role of an equivalent "plasma frequency" which depends on the geometrical parameters *a*, *b* and *r*

$$k_p^2 = \frac{2\pi/(ab)}{\log\frac{\sqrt{ab}}{2\pi r} + F(a/b)} \quad , F(\xi) = -\frac{1}{2}\log\xi + \sum_{n=1}^{+\infty}\left(\frac{\coth(\pi n\xi) - 1}{n}\right) + \frac{\pi}{6}\xi . \tag{5}$$

For the square grid ($a = b$), $F(1) = 0.5275$. Equation 4 indicates that this wire medium possesses not only plasma-like frequency dispersion, but also strong spatial dispersion.

By adopting an additional boundary condition [8], the transmission through an effective wire medium slab was theoretically studied [9]. The effective model of Eq. 4 is verified by the numerical results of the transmission- and reflection- coefficients [9].

The transmission coefficient *T* is an important parameter in studying the wire medium, especially for a sub-wavelength imaging device where *T* directly affects the quality of the image. However, it is noted that the above effective model becomes inaccurate as the transverse spatial harmonics increase. Therefore, discrepancy between the EM behaviors of the effective model and the physical structure occurs. In this study, we propose a new effective model to include higher order spatial dispersions by using higher (4^{th}) order expansion of the exact dispersion equation of the photonic states. Surface fitting is applied by using the data from a 3-D full wave simulation. Significant improvement in accuracy is demonstrated in numerical experiments.

The proposed 4 th order dispersion equation

In the following, we will first review the derivation of the transmission coefficient $T_{\text{effective}}$ in the conventional effective model [9]. Assume $q_z = k_z = 0$. Denoting $k_x = -j\gamma_x = -j\sqrt{k_y^2 - k^2}$, and the propagation constant of TM wave in the wire medium as γ_{TM}, we can obtain

$$\gamma_{TM} = \sqrt{k_p^2 + k_y^2 - k^2} \text{ , and } q_x = -j\gamma_{TM} . \tag{6}$$

By solving the system of equations for the total magnetic field, the expression of $T_{\text{effective}}$ can be obtained as follows:

$$T_{\text{effective}} = -\frac{1}{1 + \frac{\gamma_{TM} k_y^2}{\gamma_x\left(\gamma_{TM}^2 + k^2\right)}\operatorname{ctanh}\left(\gamma_{TM} d/2\right)} . \tag{7}$$

Next, we will evaluate the accuracy of the conventional effective model of Eq. 3 and Eq. 4 based on the full-wave simulation of the 3-dimensional PEC thin wire array. The FDTD method incorporating the sub-cell technique of thin wire [10] is adopted. The system is illuminated by a TM mode plane wave with an H_z excitation at operating frequency of $f_0 = 3GHz$. The corresponding wave number and wavelength in free space are denoted as k_0 and λ respectively. The length of the thin wires is $d = \lambda/2$. Wire medium with square lattice is considered in this paper. A fixed filling ratio $\pi r^2/a^2 = 0.001$ is adopted, indicating the physical thin wire array strictly meets the only assumption $r << a, b, \lambda$ in [7]. According to Eq. 5, with the increment of k_p, the lattice becomes denser roughly proportionally. For example, $a = b = \lambda/20$ corresponds to $k_p = 4.8415k_0$.

The transmission coefficient T_{FDTD} is obtained from the FDTD results with numerical error controlled under 0.05%. Based on T_{FDTD}, γ_{TM_FDTD} can be calculated accordingly. On the other hand, $T_{\text{effective}}$ and $\gamma_{TM_effective}$ are obtained analytically following Eq. 6 and Eq. 7. The comparison of γ and T for the case $k_p = 4.8415k_0$ are plotted in Fig. 2. It is obvious that with the increment of k_y, $\gamma_{TM_effective}$ and $T_{TM_effective}$ deviate from γ_{TM_FDTD} and T_{FDTD}.

In the conventional effective model, $\gamma_{TM_effective}$ corresponds to the second-order approximation of the dispersion equation Eq. 1. It increases monotonically with k_y, and the relation is linear for large k_y (ref Eq. 6). However, γ_{TM_FDTD} as a function of k_y is not a monotonic curve. That means a higher-order approximate dispersion equation is needed for describing this curve more accurately. In the following, a scheme to obtain a higher order dispersion equation corresponding to a more accurate effective model is proposed. Denote $\gamma'_{TM_effective}$ and $T'_{\text{effective}}$ as the propagation constant of TM wave and the transmission coefficient in the proposed effective model respectively. $\gamma'_{TM_effective}$ is expected to agree with γ_{TM_FDTD} better than the conventional one. Next the forth-order Taylor expansion of Eq. 1 is chosen. However, a complete solving of a fourth-order dispersion equation in obtaining $\gamma'_{TM_effective}$ is cumbersome, and the expression of $\gamma'_{TM_effective}$ is implicit. In order to express $\gamma'_{TM_effective}$ explicitly, we use the following approximations and proportional relationships

$$p_y^{(0)} = \sqrt{q_x^2 - k^2} \approx c_1 \cdot q_x + c_2 \cdot k + c_3, \quad a = c_4/k_p, \quad k_p = c_5 \cdot q_x, \quad k = c_6 \cdot q_x \tag{8}$$

where c1-c6 are the undetermined constants. Then an explicit expression of $\gamma'_{TM_effective}$ which consists of terms such as $k_y^4 k/k_p^3$, k_y^4/k_p^2, k_y^2, $k_y^2 k/k_p$ ..... k^4/k_p^2 ..... is obtained with the odd-order of k_y discarded due to the symmetry of q_x^2 on k_y. Through fitting the known surface of γ_{TM_FDTD} as a function of k_y and k_p, the dominant terms of $\gamma'_{TM_effective}$ are picked up and a neat expression of $\gamma'_{TM_effective}$ is obtained:

$$\gamma'_{TM_effective} = \sqrt{k_p^2 + k_y^2 - k^2 + \left(k_y^2 + k_p^2\right) \cdot \left(A\frac{k_y^2}{k_p^2} + B\frac{k_y^2}{k^2} \right)}, \tag{9}$$

where $A = -0.35112$ and $B = 5.22602e\text{-}4$ respectively. In the fitting process, the residual sum of squares is 4.75322 for 106 points and the Adjusted R-Square is 0.99893. The form of γ'_{TM} ensures that the TM and TEM (corresponding to $q_x = k$) modes exist in the wire medium (ref. [7] and [9]). Because of the symmetry of the structure in the y- and z- directions, a general form of the 4th order approximate dispersion equation can be written as:

$$q_x^2+\left(q_y^2+q_z^2+k_p^2\right)\left(A\frac{q_y^2+q_z^2}{k_p^2}+B\frac{q_y^2+q_z^2}{k^2}+1\right)=k^2\,. \tag{10}$$

The corresponding 4th order effective model is derived following the similar steps in [7]:

$$\varepsilon\left(k,q_x,q_y,q_z\right)=\varepsilon_0\left(\frac{1}{A\frac{q_y^2+q_z^2}{k_p^2}+B\frac{q_y^2+q_z^2}{k^2}+1}-\frac{k_p^2}{k^2-q_x^2}\right). \tag{11}$$

The fitting curve of $\gamma'_{TM_effective}$ with $k_p=4.8415k_0$ is shown in Fig.2. It can also be seen from Fig.2 that the calculated $T'_{effective}$ agrees with T_{FDTD} much better than $T_{effective}$. That shows the proposed 4th order effective model is more accurate than the conventional 2th order effective model.

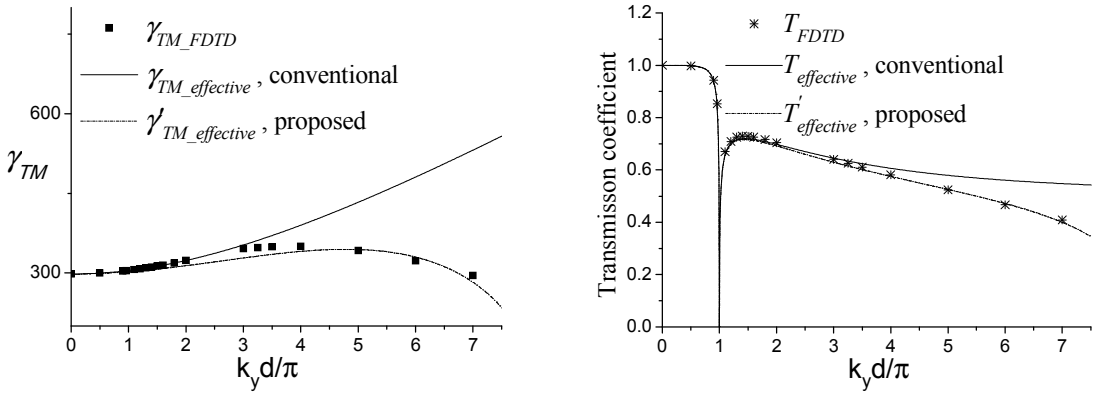

Fig. 2. Comparison of γ and T obtained by using different models as functions of the transverse wave component k_y.

Validation

The above numerical experiments are based on wire medium of square lattice. Next, the proposed 4th order effective model is applied to a different type of wire medium. This medium is based on a rectangular lattice (*b=1.5a*), and the rest parameters are the same with the above examples. The analytical results are compared with the FDTD results in Fig. 3. It is clearly shown that the proposed higher-order effective model can describe the characteristics of the wire medium with improved accuracy for different types of wire media compared with the conventional model.

Summary

In this paper, the wire medium which consists of parallel metallic thin wires is simulated by using the FDTD method incorporating the sub-cell technique of thin wire. The FDTD results show that the conventional effective model based on the 2nd order Taylor expansion of the exact dispersion equations fails to describe the EM behavior accurately for high spatial harmonics. Then a new effective model is proposed by using the surface fitting method based on the 4th order Taylor expansion of the exact dispersion equations. Compared with the conventional model, the proposed model improves the modeling accuracy for a higher spatial harmonics. Numerical experiments also shows that this model is general suited for various type of wire medium.

Keywords: FPGA; DDS; Howland current pump; sweeping constant current source

Abstract: This paper designed a range of 0.1 ~ 250 kHz sine wave sweeping constant current source, which sine wave generator based on FPGA chip and DDS technology, the desired sine wave frequency was obtained by controlling the frequency control words. Low-pass filter circuit was realized by using the LTC1560-1, conversion circuit from the voltage to the current was consisted of a Howland current pump. The constant current source shows a good spectral impedance purity and amplitude.

Introduction

The factors, such as fat, moisture, tenderness and freshness, are important performance indexes for evaluating meat quality. It is a new field of application of bio-impedance technology to analyze these quality factors by impedance spectroscopy in recent years. The experiment showed that: when the current frequency is less than 50 Hz, the current flows mainly through the extra cellular fluid, the extra cellular fluid resistance was measured; but at higher frequencies, such as 200 kHz or more, current can be through the cell membrane. Because of different tissues characteristics and composition of components, meat can show different impedance characteristics corresponding to different quality [1]. Meat impedance characteristics showed that poultry meat quality measurements can be achieved by bioelectrical impedance measurement and analysis.

There are many relevant reports for impedance spectroscopy analysis methods. Both the implementation of automatic sweep signal source and the separation of the real and imaginary parts of the impedance are key technology. Because of changes of the complex impedance of tissue from the body with time, activated signal (frequency range from low to high or from high to low in turn be loaded into the tested target) must be completed in short enough time, which required very short current source frequency switching time. Therefore, it is the first condition to provide a stable frequency drive current to ensure system accuracy and reliability [2].

Design of Sweep Constant Current Source

The Structure of Sweep Constant Current Source

The circuit structure of voltage-controlled current source is shown in Fig.1. signal generator generates a sinusoidal signal of different frequency and voltage amplitude; filter circuit can deal with the signal frequency beyond useful frequency range; the circuit of voltage followed is used to match impedance and enhance the driving capability of the voltage signal; the voltage-current conversion circuit can change the sinusoidal voltage signal into a current signal of the same frequency.

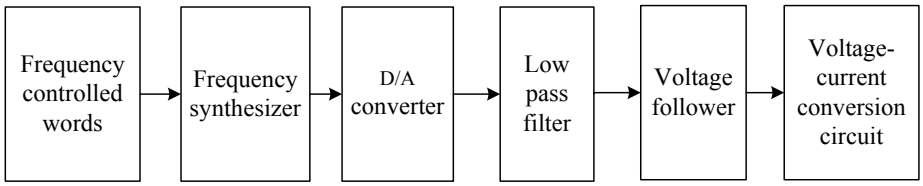

Fig.1 Sweep constant current source circuit block diagram

Voltage Source Signal Generated Circuit Based on DDS Technology

According to the measure system, sweep range is from 0.1 to 250 kHz, impedance values can show the different impedance characteristics of meat tissue from low frequency to high frequency and be able to more fully reflect the impedance characteristics, thereby these factors associated with meat quality. The frequency range of measurement system is 0.1Hz ~ 250 kHz, sweep step is variable, when the frequency is less than 1kHz sweep at the interval 100 Hz, at 1 ~ 10kHz, sweep interval is selected 1kHz, at more than 10 kHz sweep interval is selected 10 kHz. DDS technology is used to build a sine wave signal generator in this system [3], it is shown in Fig 2.

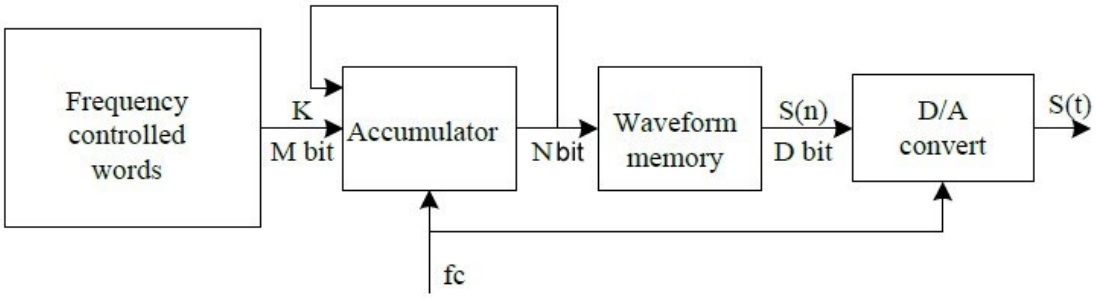

Fig.2 DDS sweep signal source block diagram

Where K is the frequency control word, M, 28 bit, is controlled word length to control the frequency, fC is the system clock frequency, N, 32 bit, is the word length of the phase accumulator, and ROM data bit has the same length with D / A converter word length, both are D. equation (1) is the output signal frequency fout.

$$f_{out} = \frac{K \times f_c}{2^N} \tag{1}$$

According to equation (1), when the reference clock is determined，according to the range of the output frequency, the frequency control word can be obtained:

$$K = \frac{f_{out} \times 2^N}{f_c} \tag{2}$$

Different frequency controlled word K is stored in the look-up table in sequence, the result needed in the look-up table can be obtained by the sweep controller to give the desired signal source frequency. System clock is 16MHz, frequency controlled word length is 28.

In this design, the length of D is 12 bit. the phase accumulator is incremented by step K , the accumulator outputs N-bit binary code in the system clock fC, the length of the data needed is intercepted to quantify ROM address bits as address of the waveform ROM, the output waveform amplitude of ROM code S (n) becomes ladder wave S (t) by the D / A converter, D/A converter adopts TI's high-speed digital to analog converter DAC2904, its switching frequency up to 125MHz, which can guarantee a constant current source for the design phase requirements [4], and then smoothed by the low-pass filter, a synthesis signal waveform can be obtained.

The Low Pass Filter

The design adopted LTC1560-1 of Linear Technology as the low pass filter which used 5th order, continuous-time, low-noise, low-pass elliptic filter. Without connecting external components it can constitute a high-performance LPF, which f_C, its cut-off frequency, is 500 kHz or 1MHz. When connected pin 5 to V+, f_C is 500 kHz. ± 5V power supply for LTC1560-1, and has a power-off mode (controlled by pin 7). The cut-off frequency 500kHz was designed by elliptical low-pass filter circuit in the system. Fig.3 VI is LTC1560-1 input signal that connected to the output of the signal generator, the filtered signal output from 8 feet to output buffer U3. In idle state, FPGA can control SHDN (Pin 7) to shut off power.

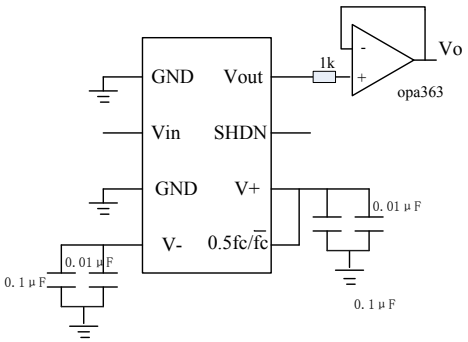

Fig.3 Low-pass filter circuit

The Voltage-Current Conversion Circuit Based on Howland Current Pump

Voltage current conversion circuit is shown in Fig.4.

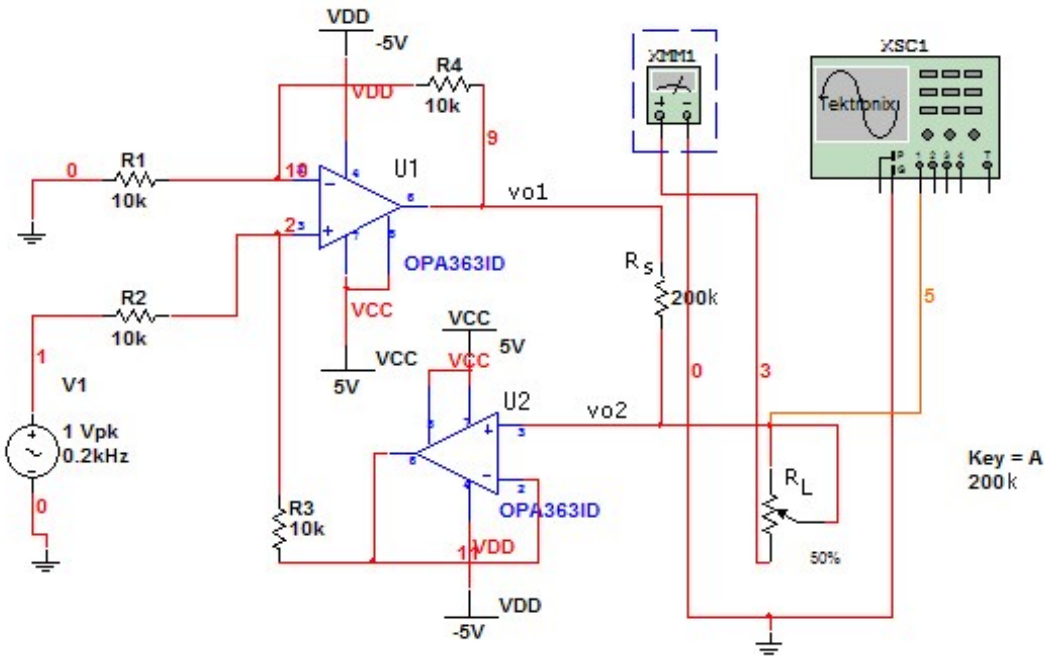

Fig.4 Voltage-current conversion circuit

When the operational amplifier operates in the linear region, the two input terminals of the amplifier is approximately short-circuited, the current through the conversion resistor R_S is equal to the current flowing through the load R_L, the potential of the inverting input terminal V- equals to that of the no-inverting input V+, so the following equations can be gotten[5]:

$$v_+ = \frac{R_4 v_i + R_3 v_{o2}}{R_3 + R_4} = \frac{R_1}{R_1 + R_2} v_{o1} = v_- \tag{3}$$

$$v_{o2} = i_s R_L \tag{4}$$

$$v_{o1} = i_s \left(R_s + R_L \right) \tag{5}$$

It can be obtained from the above equations:

$$i_s = \frac{R_1 R_4 + R_2 R_4}{(R_1 R_3 + R_1 R_4) R_s + \left(R_1 R_4 - R_2 R_3 \right) R_L} v_i \tag{6}$$

Assumed R1R4=R2R3, then equation (6) can be expressed:

$$i_s = \frac{R_1 R_4 + R_2 R_4}{R_1 R_3 + R_1 R_4} \frac{v_i}{R_s} \tag{7}$$

Equation (7) showed that the output current i_s is independent of the load resistance R_L in voltage-current conversion circuit, only which is proportional to the input signal voltage under ideal conditions, R_1~R_4 met the condition of $R_1R_4=R_2R_3$, so the suitable external resistors are the key of the stability and reliability of output current. In practice, Accuracy of resistor value chosen is 0.5% or even 0.1%, in this system, R_1~R_4 consisted of a fixed resistor and resistor trimming resistor in series, which adjusted the trim resistor to ensure resistor value matched. If further assume $R_1=R_2=R_3=R_4$, which the equation (7) can be simplified as:

$$i_s = \frac{v_i}{R_s} \tag{8}$$

As can be seen from the above equation, the output current i_s is completely determined by input voltage signal v_i and resistor Rs.

Simulation of Constant Current Circuit

With Multisim Software simulation, input sinusoidal voltage amplitude is 1 V, under changing the excitation signal (the range of 0.1-250kHz) and different load values, the simulation results are shown in table 1, current value measured is RMS value.

Table 1

I/mA f/kHz / R/Ω	0.1kHz	0.3kHz	0.5kHz	1kHz	10kHz	20kHz	50kHz	100kHz	200kHz	250kHz
R=10Ω	5.096	3.853	3.657	3.567	3.533	3.533	3.538	3.539	3.551	3.550
R=30Ω	4.899	3.825	3.647	3.564	3.532	3.533	3.537	3.543	3.546	3.544
R=50Ω	4.709	3.796	3.636	3.560	3.533	3.533	3.537	3.543	3.545	3.540
R=80Ω	4.436	3.749	3.619	3.555	3.532	3.534	3.537	3.542	3.537	3.531

R=100Ω	4.265	3.716	3.606	3.552	3.532	3.533	3.536	3.542	3.537	3.527
R=120Ω	4.108	3.682	3.593	3.549	3.532	3.534	3.537	3.541	3.532	3.519
R=150Ω	3.874	3.637	3.572	3.545	3.532	3.533	3.537	3.539	3.526	3.506
R=180Ω	3.664	3.572	3.550	3.537	3.533	3.533	3.536	3.538	3.516	3.496
R=200Ω	3.534	3.533	3.533	3.533	3.532	3.534	3.536	3.535	3.510	3.487

From the above table it can be obtained, when the frequency is from 0.3 kHz ~ 1kHz, the range of the impedance value from 100Ω~ 200Ω, the variation range of the output current varies with load is less than 0.11mA. When the frequency is greater than 1kHz, and the range of change of the current with the load change is smaller than 0.04mA, it achieved to the constant current standard.

Conclusions

This design of sine sweep constant current source adopted FPGA chip, it is easy to implement and to set fast frequency value; LTC15602-1 made the amplitude of the sinusoidal signal better stability and spectral purity; Howland current pump made the current source of stable output by voltage controlled; application of low-power chip and power-off mode deduced power consumption of the entire system.

Keywords: manual anthropometry; view angle deviation; height data; circumference data

Abstract. In the actual work of manual anthropometry, there is a distance between the height of measurers' horizontal sight and the height of the measured body parts, the distance can result in a non-horizontal observation view angle. To explore the phenomenon, this study obtained a lot of manual anthropometric measurement data, on the basis of these data, screened some data influenced by the view angle deviation. Furthermore, using mathematical analysis software, make the data do packet sampling and ANOVA test. After these data analysis, we got the result that the view angle deviation could make influences on those height data and circumference data, but the potential influence degree was different among these data.

Introduction

At present, the forefront of anthropometry has focused on 3D anthropometric technology [2]. This technology has entered the stage of applications, with the purpose to realize the clothing size standardization, but also to promote the development of digital garment customization system [1,3]. However, due to many factors, such as the clothing industry lacking of computer technology application talents, and capital investment, the industry is still widely using manual anthropometric methods [5]. Therefore the content discussed in this paper is still mainly in the service of manual anthropometric. In the actual manual measurement, the measurers touch the body parts directly. According to the manual anthropometric principles and methods, the measurers try their best to control the accuracy of the measurement data, but it still can't avoid data deviation. The factors come from various aspects, but this study mainly focus on the effect of measurers' view angle deviation on the measurement data.

Scientific research proved that if you observe cylinder in a non-horizontal view angle, the data you read will exist deviation [7]. Similarly, looking down or looking up in the measurement process can also appear the same deviation. Therefore, utilizing measurers in different height measuring the same subject to simulate the phenomenon, it converted the view angle deviation to the distance between the height of the measurers' horizontal sight and the height of the measured body parts, so as to facilitating the experiment. Firstly, gained a large number of manual measurement data. Secondly, analyzed experimental data for the reasons of view angle deviation. Thirdly, using mathematical analysis software, make the data obtained do packet sampling and ANOVA test. Finally, analyzed and evaluated the mathematical results. This study can enrich the manual anthropometric experience, enhance the measurement accuracy, and will play a supporting role in improving the three-dimensional anthropometric technology.

Methodology

Previous Work

Selected fifteen measurers with certain measurement level randomly, six men as subjects, aged from 20 to 25 years old, height from 165 cm to 185 cm. Besides, the experimental equipment included Martin-type Authropolometer, tape, triangle, sitting ruler, record boards, etc. During each

experimental process, decorated the same environment, the measurers used the same manual techniques. At the same time, ensured the consistency of the equipment specifications.

Experimental Process

It is necessary to have a correct and objective understanding to the human body. Generally, the measurement data includes two aspects: height data and circumference data. This study selected four kinds of height data and three kinds of circumference data. The measurement methods just as follow.

Height Measurement Methods

Neck base height(lateral) (I): use Martin-type Authropolometer measure the vertical distance between the standing surface and the trapezius landmark on the right side of the neck. Waist height (II): use Martin-type Authropolometer measure the vertical distance between the standing surface and the waist line. Out seam (III): use tape measure the surface distance from waist to ankle. Crotch height (IV): use Martin-type Authropolometer measure the vertical distance between the standing surface and the crotch.

Circumference Measurement Methods

Chest circumference (V): use tape measure the maximum horizontal circumference of chest at the fullest part. Waist circumference (VI) : use tape measure the horizontal circumference of waist at the level of its nature indentation, passing over right and left waist (nature indentation) landmarks. Hip circumference (VII): use tape measure the horizontal circumference of the truck at the level of the maximum protrusion of the right buttock.

Data Collection

Standard Data Collection

Three skilled measurers acquired measurement data from the six subjects. Then the data analysis showed that the data was available. Finally, got the average of the three groups of human body size data as the standard data.

Experimental Data Collection

The fifteen measurers were trained the basic manual measurement technique by the three skilled measurers. After they met the basic technique requirement, then did manual measurement. The measurers in different height were in the same pose when they measured the same body part, so the view height was different, and the view angle was different. Specific view angle deviation phenomenon of measurement as shown in figure 1.

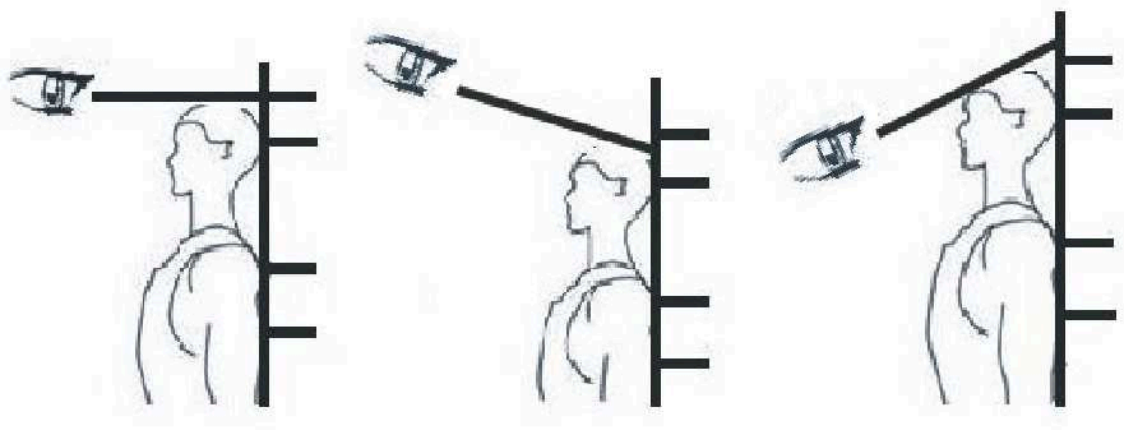

Figure 1 The View Angle Deviation Phenomenon

View Angle Deviation Degree Classification

The classification was based on the distance between the height of the measurers' horizontal sight and the height of the measured body parts. While measures stood vertically, the height of measured body parts was always lower than the height of the measurers' horizontal sight. So the measurers had to stoop or bend down. Therefore, the more higher was the measurer, the more lower would he bend down, then the view angle deviation degree would be greater. In order to make the influences more clearly, the data research chose the sample whose height is 181cm of a male body data, it made a significant height distance. As to the sample data, the view angle deviation degree classification as shown in table1. From the table1, we can see that the degree of the measurer' view angle deviation was in the tendency of uniform narrowed gradually, from A to B, to C, and to D.

TABLE1 THE VIEW ANGLE DEVIATION DEGREE CLASSIFICATION OF THE SAMPLE （WHOSE HEIGHT IS 181CM）

Measurers' height[cm]	View distance as to the sample[cm]	Number of view angle deviation degree classification
170	17	A
165	12	B
160	7	C
155	2	D

Data Analysis

Analysis Process Description

Firstly, compared the experimental data with the standard data, got the arithmetical average deviation, then preliminary analyze the numerical accuracy differences. Secondly, on the base of the preliminary analysis, used the method of mathematical statistics, made the data do packet sampling and ANOVA test. Then tested the numerical discrete significance and grouping with significant.(It indicated that the factor can make influences if any groups, otherwise no effect.) Finally, builded single-factor model to accurately explain the influences that the view angle deviation made on those measurement data. Furthermore, speculated the influences degree according to the numerical laws. The assumption for data samples with F is $H_o: \mu_1 = \mu_2 = \cdots \mu_K$, $H_A: u_i$ not all equal. If the calculated value is larger than $F_{\alpha(df1,df2)}$, then receive the hypothesis H_A, and it indicates that the factor can make significant effects. On the contrary, accept H_0, it illustrates the factor is not significant. At the same time, cooperated with Duncan statistics to compare the influence degree that different factors made on the data .

$$F = MS_t^2 / MS_e^2 \quad (1)$$

$$MS_t = SS_t / df_t \quad (2)$$

$$MS_e = SS_e / df_e \quad (3)$$

$$SS_t = \sum_{i=1}^{k} n_i \left(\overline{x_{i_n}} - \overline{x_{...}}\right)^2 \quad (4)$$

$$SS_e = \sum_{i=1}^{k} \sum_{j=1}^{n_i} \left(x_{ij} - \overline{x_{...}}\right)^2 \quad (5)$$

$$df_t = k - 1 \quad (6)$$

$$df_e = N - k \quad (7)$$

Preliminary Data Analysis

Compared the experimental data differences, preliminary analyzed whether the measurers' view angle deviation can make influences on those height data and circumference data. The changing tendency of the measurement data with different view angle deviation as shown in figure 2.

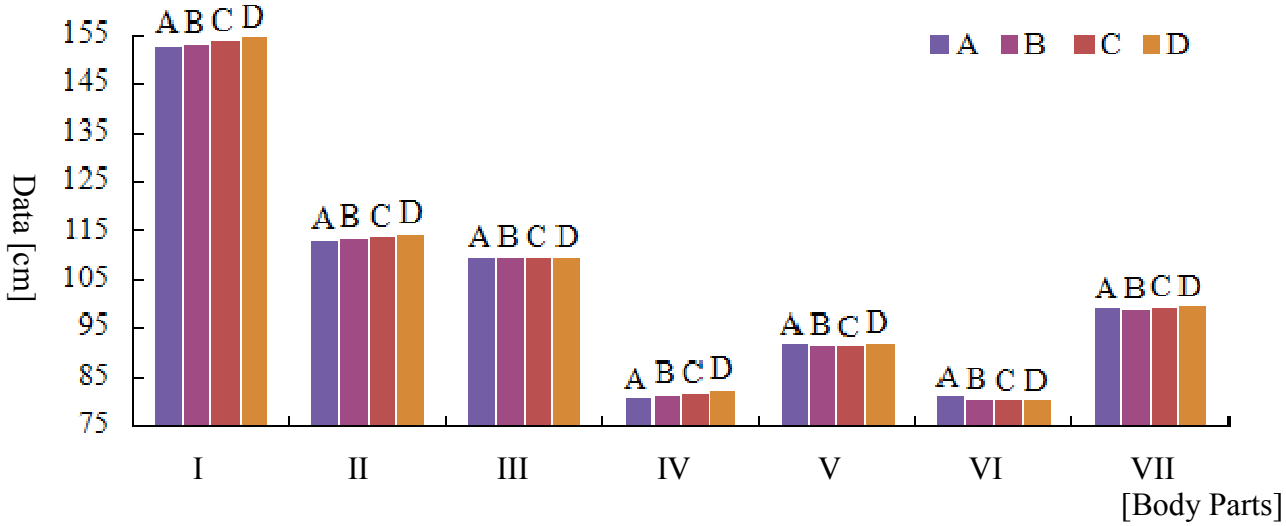

Figure 2 The measurement Data of Different View Angle Deviation

The figure 2 indicated: on the one hand, based on the standard height data, neck base height(lateral), waist height, and crotch height showed obvious changing trend, while out seam did not show any trend of change. The data phenomenon meaned the view angle deviation could make effects on the the three data accuracy, while the data of out seam did not show a significant change. On the other hand, chest circumference, waist circumference, and hip circumference were floating within the corresponding standard data scope, but did not present obviously changing tendency. This data phenomenon showed that the view angle deviation did not make a certain trend on the accuracy of the three circumference data.

Height Data Analysis

Using the mathematical analysis software, made the height data do packet sampling and ANOVA test. We got the result as shown in table2.

TABLE 2 DUNCAN ANALYSIS OF THE HEIGHT DATA(FOR THE SAMPLE 181CM)

The classification number/ Experimental times	The significance grouping of neck base height(lateral)		The significance grouping of waist height		The significance grouping of out seam	The significance grouping of crotch Height	
	1	2	1	2	1	1	2
A/6	148.83		110.67		106.33	78.15	
B/10	149.46		111.60	111.60	107.04	78.43	78.43
C/10	149.32		111.40	111.40	107.05	79.00	79.00
D/8		150.68		112.00	106.96		79.61
Significance	0.27	1.00	0.10	0.28	0.05	0.19	0.07

According to the table2, we found that, among the four height data involved in the analysis, in addition to out seam, all the other three data showed a significant phenomenon of grouping. Therefore, the view angle deviation did affect the accuracy of the three height data.

In addition, we also found the following data feature: First, the degree of the view angle deviation changed with the changing of the distance between the height of the measurers'

horizontal sight and the height of the measured body parts, then the data accuracy changed as well. Second, based on the comparison and analysis, the height data generated significant differences. The sight distance was bigger, the disparity between experimental data and standard data was bigger, the data accuracy was lower. For the out seam, whose data showed no significant differences, its measurement method was using tape measure the surface distance from waist to ankle. The method was different compared with the other three height data, and the view angle was different, as a result, it showed no same data appearance .

Circumference Data Analysis

Using the mathematical analysis software, made the circumference data do packet sampling and ANOVA test. We got the result as shown in table 3.

TABLE 3 DUNCAN ANALYSIS OF THE CIRCUMFERENCE DATA(FOR THE SAMPLE 181CM)

The classification number/ Experimental times	The significance grouping of chest circumference	The significance grouping of waist circumference	The significance grouping of hip circumference
	1	1	1
A/6	91.58	81.02	99.12
B/10	91.30	80.50	98.67
C/10	91.36	80.24	99.36
D/8	91.83	80.45	99.38
Significance	0.07	0.09	0.04

According to the table3, we found that, all the three circumference data showed no significant grouping. Therefore, the view angle deviation of measurers did not affect the accuracy of the three circumference data. The three circumference measurement method was using the tape measure the circle distance, this progress did not make large view angle deviation. Therefore, the related circumference data did not show obvious changing trend and significant grouping phenomenon.

Conclusions and Further Work

Through data collection and analysis got the following conclusions:

On the one hand, while did manual measuring, the view angle deviation of measurers made some influences on the three height data, whose measuring tool was Martin-type Authropolometer. The reason was that, the three height data appeared significant grouping. During the progress of using Martin-type Authropolometer, the height of measurers' horizontal sight and the measured body parts was different, this distance resulted in a non-horizontal observation view angle. Finally, the view angle deviation affected the three height data accuracy.

On the other hand, while did manual anthropometry, the view angle deviation of measurers made no obvious influences on the three circumference data, whose measuring tool was tape. The reason was that, the three circumference data did not appear significant grouping. During the progress of using tape, the height of measurers' horizontal sight and the measured body parts was different, the distance did not result in a significant non-horizontal observation view angle. Finally, the accuracy of the three circumference data appeared higher and more stable.

Due to the limited experimental content and data analysis, it is unable to show that, during the measurement progress of using Martin-type Authropolometer, the view angle deviation will make differences on all actual measurement data. So it is necessary to go deep into measurement study.

Keywords: engine, fault diagnosis, time domain, frequency domain.

Abstract. Engine is as a power machine, the operating status is good or bad, directly affects the working status of equipment. The status monitoring and fault diagnosis is very necessary to ensure that the equipment runs in its best, and improves equipment maintenance quality and efficiency. The engine failure shows the complexity and diversity of the interaction and complex relationship between the various subsystems of the engine, that is the fault of complexity, ambiguity, correlation, relativity and multiple faults coexistence. The available information are much in the engine diagnosis, for example, the vibration signal from bearings, cylinder head or cylinder block surface; oil, cooling water, pressure of intake, exhaust and fuel; temperature signal; noise, speed or oil-sample signals. In this paper, an engine as an example, engine fault diagnosis experimental system is built, the normal state, left one and right six cylinders off the oil, air filter blockage (inlet wood blockage is 30%, the inlet has screen cloth.) in the load of 2565Nm, and the speeds of 1500r/min, 1800r/min, 2200r/min are studied. The experimental results analysis, feature extraction and fault diagnosis are finished based on the time domain and frequency domain.

Introduction

As a typically reciprocating engine power machine, complex structures of the engine determine its failures show the characteristics of complexity and diversity. The impacts of uncertainties, induced by such as operating environment, system noise and sensor accuracy, result in reducing the accuracy of engine fault diagnostic. There are many available diagnostic information in the engine, such as the vibration signal from the bearings, cylinder head or cylinder block surface; oil, cooling water; pressure of intake, exhaust and fuel, temperature signal; noise, speed or oil-sample signals, etc.. Each type signal contains a large amount of information, taking into account the complexity, nonlinearity and uncertainty of engine dynamic behavior, the function and structure, and rely only on a small amount of information or a single information diagnosis is obviously not comprehensive, it is difficult to make an accurate evaluation on the whole engine conditions. In this paper, an engine as an example, engine fault diagnosis experimental system, experimental results analysis, feature extraction and fault diagnosis are finished based on the time domain and frequency domain [1].

Engine Fault Diagnosis Experimental System

The acquisition and analysis of the experimental system based on the vibration signal and TDC signal are shown in Fig.1. Piezoelectric sensors collected vibration signal, TDC sensor samples TDC signal, amplification processing by the multi-charge amplifier, enters the DASP data acquisition system, and achieve the fault diagnosis of the engine by the computer signal analysis system and data analysis processing.

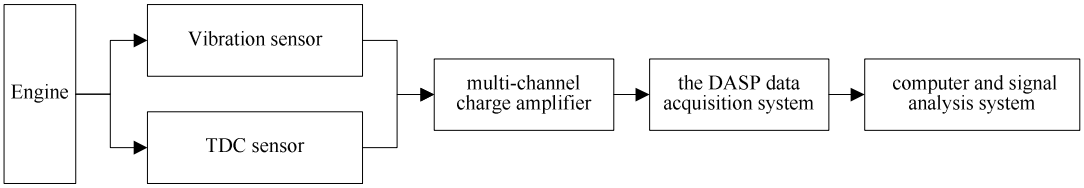

Fig.1 Signal acquisition and analysis works principles of engine system

Sample Types and Experimental Procedures

The vibration signal of the cylinder head, the cylinder block and a TDC signal of V12 cylinder diesel engine in different revolving speeds are collected when the throttle opening is controlled in 100% working conditions. Based on the possibility of failure in the diesel engine actually running process, the vibration signal of the cylinder head and cylinder body of the engine are measured by the signal acquisition system in the normal state, left one and right six cylinders off the oil, air filter blockage (inlet wood blockage is 30%, the inlet has screen cloth.) in the load of 2565Nm, and the speeds of 1500r/min, 1800r/min, 2200r/min.

Experimental Results Analysis and Feature Extraction

When the experimental requirements conditions are met, in order to improve the signal to noise ratio, the measured vibration signals are carried out pre-processing, they include filtering, mean, eliminating the trend, and then the required characteristic parameters of time domain and frequency domain are extracted. The fault-sensitive feature vectors are selected to be able to accurately identify the fault status of engine [2].

Time Domain Feature Extraction of Vibration Signals

Time domain analysis is the process to record the amplitude of measured signal and the law of energy distribution with changing over time, and analyzes the composition and characteristics of signal, and it includes time-domain waveform analysis and the amplitude domain parameter analysis.

The characteristic parameters of amplitude domain include the dimension characteristic parameters and the dimensionless characteristic parameters. Many sensitive failure characteristic parameters of engine are selected, the dimension parameters include RMS, skewness, kurtosis, variance; the dimensionless parameter include margin index, skewness index, kurtosis index, waveform indicators, peak indicators and pulse indicators.

Experiments analysis select three states of engine, they are the normal state F1, left one and right six cylinders off the oil F2, clogged air filter F3 in speed of 1500r/min, the sampling frequency is 40kHz, the vibration signals of three measurement points are dealt with in the different conditions, the original time-domain curves are shown from Fig.2 to Fig.3, the domain characteristic parameters of measuring point 2 in the F1 is shown in Table 1.

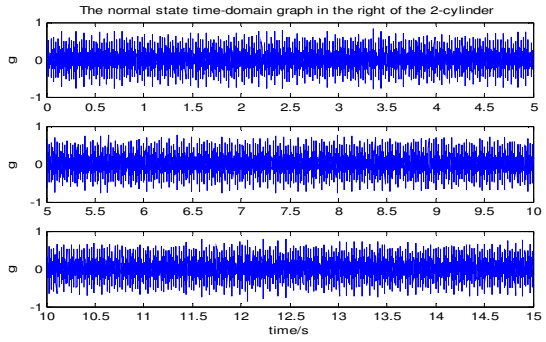

Fig.2 The Normal State

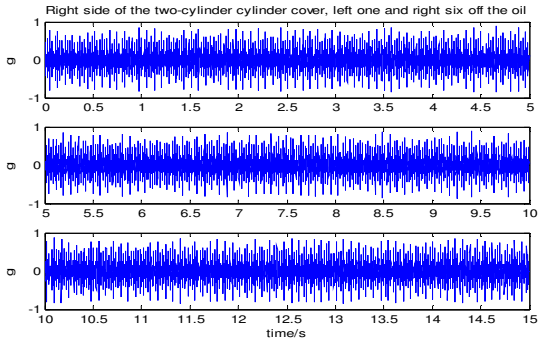

Fig.3 Left One And Right Six Off The Oil

Table 1 Time Domain Indexes In Test 2

Measured	RMS	Skewness	kurtosis	variance	margin index	skewness indicator	kurtosis indicators	waveform indicators	peak indicators	pulse indicators
Normal state	5.1647	2.1973	2143.2	26.686	5.4238	0.4225	3.0073	1.2582	3.6259	4.5744
Left 1, right 6 cylinder off oil	6.6330	-15.531	5386.9	44.046	5.2738	-2.3708	2.7834	1.2263	3.6977	4.5357
Filter clogging	4.9528	-0.2445	1886.8	24.551	5.4001	-0.0262	3.1245	1.2640	3.6031	4.5538

The contrast from Fig.2 and Fig.3 can be seen that peak and RMS of the normal state and fault condition are not same.

By contrasting the characteristic parameters of Table 1 in the normal state and fault conditions can be seen that RMS changes in the event of failure are not large; Skewness and skewness index decrease significantly, they indicate that the probability density curve gravity center of failure signal is very asymmetry; Kurtosis changes evidence, kurtosis indicators correspondingly increase or decrease, it indicates that the convex of the probability density curve peak has changed, and the occurrence of local or overall defects; variance significantly increase or decrease descript the fluctuation is relatively large of the signal vibration amplitude; margin index decreases when the left 1 and right 6 cylinders off the oil, it indicates the signal impacts weakened; waveform index changes a little, it indicates its stability is good[3].

The Characteristic Parameter Extraction of the Vibration Signal in the Frequency Domain

Time-domain analysis is generally used only for simple diagnosis, and frequency domain analysis can determine the failure position. It can reflect the change in signal frequency-domain characteristics by changing gravity center location and the dispersion degree of spectral energy distribution in the power spectral. The following frequency domain characteristic parameters reflect the power spectrum changes are selected, and they are power spectral gravity center indicator, mean square spectral variance, related factor, harmonic factor and spectral origin moment [4].

The spectrum of each measuring point in three states are shown from Fig.4 to Fig.7, the frequency-domain characteristic parameters are shown in Table 2.

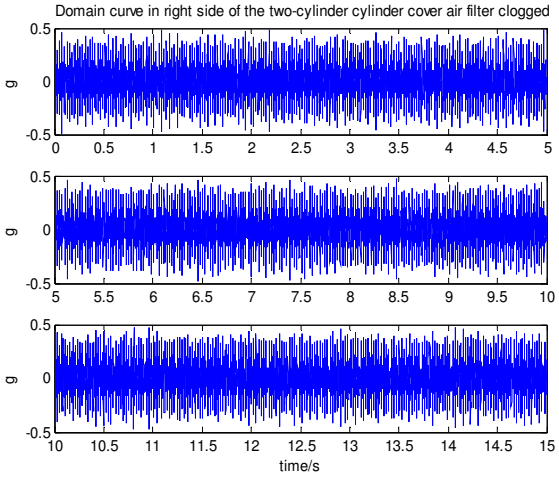

Fig.4 Cylinder Cover Air Filter Clogged

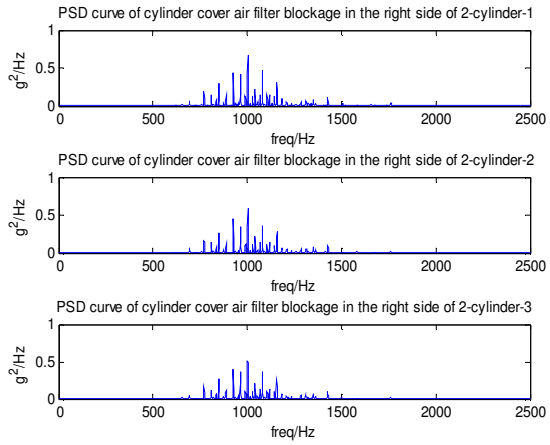

Fig.5 Psd Curve Of Cylinder Cover Air Filter Blockage

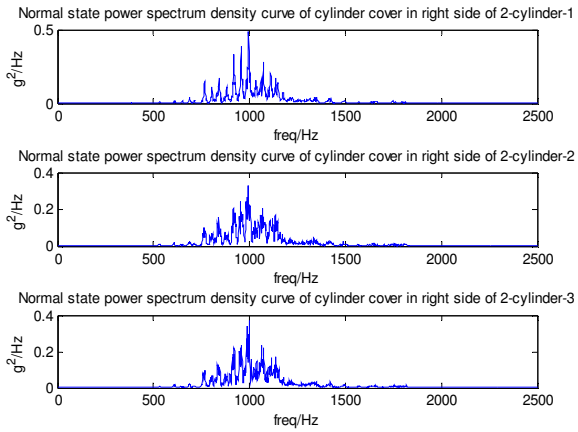

Fig.6 Psd Curve Of Normal State

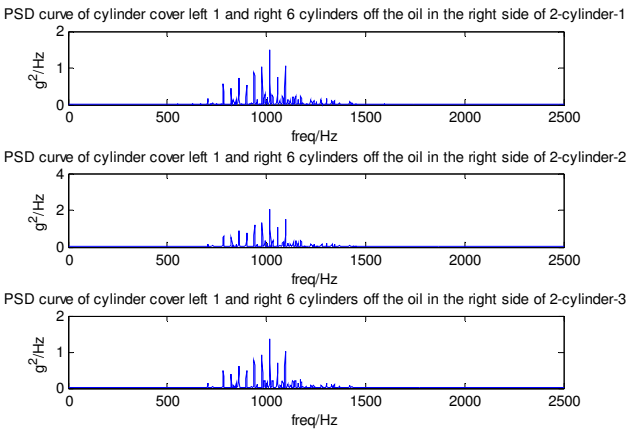

Fig.7 Psd Curve Of Left 1 And Right 6 Cylinders Off The Oil

TABLE 2 THE FREQUENCY DOMAIN CHARACTERISTIC PARAMETERS IN RIGHT SIDE OF 2-CYLINDER

Measuring point 2	power spectral center of gravity indicator	mean square spectral variance	related factor	harmonic factor	spectrum origin moment
Normal state	961.2321	739905	-0.0930	3.2701	9246098
Left 1 and right 6 cylinders off oil	1017.1340	314480	0.1420	2.0271	7858194
Air filter clogging	994.1660	665406	-0.0360	3.0281	8048218

Frequency domain characteristic parameters can be seen by contrasting the normal state and fault state in Table 2, the power spectral gravity center indicator increases in the left 1 and right 6 cylinders off the oil, the mean square spectral variance and spectral origin moment are significantly reduced. Because of reducing the amplitude of the vibration signal at this time, the position of power spectrum gravity center shifted to the right, while the related factor increases, it shows its energy is more dispersed, the harmonic factor decreased shows that the spectral width decreases [5].

Comparison Fig.5 and Fig.7 can be seen, the measured cylinder cover power spectrum gravity center of index increases in the right side two-cylinder when air filter is clogged, the rest of characteristic parameters change just opposite with the left 1 and right 6 cylinders off oil. By contrasting Fig.5 and Fig.7 can be seen, the frequency spectrum in different conditions and different measurement points are not the same, frequency-domain characteristic parameters will change.

Conclusions

It can be seen by analyzing the vibration signal of engine status and fault status, the extracted characteristic parameters of time domain and frequency domain can reflect the changes of the engine status. The vibration signal of the four points are collected in three conditions, and characteristic parameters of time domain and frequency domain are extracted, and the signs of engine failure are acquired, and fault diagnosis of diesel engines are finished.

Keywords: Data mining , Particle Swarm Optimization Algorithm , Decision tree, Transportation，ID3

Abstract： For the relationship of environmental parameters and variables in the each transport process, by using data mining, the system gets the corresponding decision tree. In a certain environment parameters conditions, the occurrence of the event is determined by the decision tree. Through the No Free Lunch Theorem (NFL) revelation, the original PSO algorithm is improved to enhance the validity of the original decision tree. To the final experiments results, once again demonstrate the improved algorithm is efficient.

Introduction

As we all know, incidents such as collision, falling during transportation will cause huge economic losses, therefore how to effectively control the occurrence of the incident has become a pressing issue. We found that the emergency is to some extent associated with the environmental parameters, through the measurement of the related hardware. If we can seize the potential relationship between the two, we will be able to effectively control the occurrence of unexpected events. We separate part of the data derived from the measured data to data mining .Successively, data cleaning, data integration, data loading change, data mining, pattern evaluation, knowledge representation, We can get the knowledge ,that transportation process parameter changing cause events. Analyse the present conditions through the knowledge, to make effective prevention and timely treatment to reduce the financial losses, which can be called as the Miracle Fighters of the new era.

ID3 Algorithm

Let S is a set containing s data samples, the set category attribute takes m different values, corresponding to m different categories C_i, $i \in \{1,2,3,\ldots,m\}$. S_i is assumed to be the number of the samples in the class C_i, then the amount of information needed to classify the given data set can be computed as Eq. 1,P_i is the probability that any data object belongs to the category C_i. Use S_i/S to calculate.Set an attribute A take v different values $\{a_1, a_2,\ldots,a_v\}$, the collection S is divided as attribute A

$$I(s_1, s_2, \ldots, s_m) = -\sum_{i=1}^{m} p_i \log(p_i) \tag{1}$$

The subsets $\{S_1, S_2, \ldots, S_v\}$, in which S_j contains the data samples with the attribute A getting the value of a_j, adenoted s_{ij} for the number of samples which the subset S_j belong to attribute C_i, then the information entropy required to classify the collection T in accordance with attribute A: Eq. 2

$$E(A) = \sum_{j=1}^{v} \frac{s_{1j} + s_{2j} + \ldots + s_{mj}}{s} I(s_{1j}, s_{2j}, \ldots, s_{mj}) \tag{2}$$

the smaller E (A) is, the more successful the set is divided, in which $I(s_{1j}, s_{2j}, \ldots s_{mj})$ represent the information entropy to divide the subset S_j,: Eq. 3

$$I(s_{1j}, s_{2j}, \ldots, s_{mj}) = -\sum_{i=1}^{m} p_{ij} \log(p_{ij}) \tag{3}$$

Wherein $P_{ij} = s_{ij}/S_j$,is the probability that any data sample of subset S_j, belongs to the class C_i, then the information gain dividing the current node as attribute A can be calculate as follows: Eq. 4

$$Gain(A) = I(s_1, s_2, \ldots, s_m) - E(A) \tag{4}$$

According to the ID3, we can easily achieve the corresponding decision tree based on the data of the transport process , code the VC++ program. The validity of the resulting decision tree is 0.682243. Classify and organize the same branch of the decision tree in Fig. 1, the original decision tree.

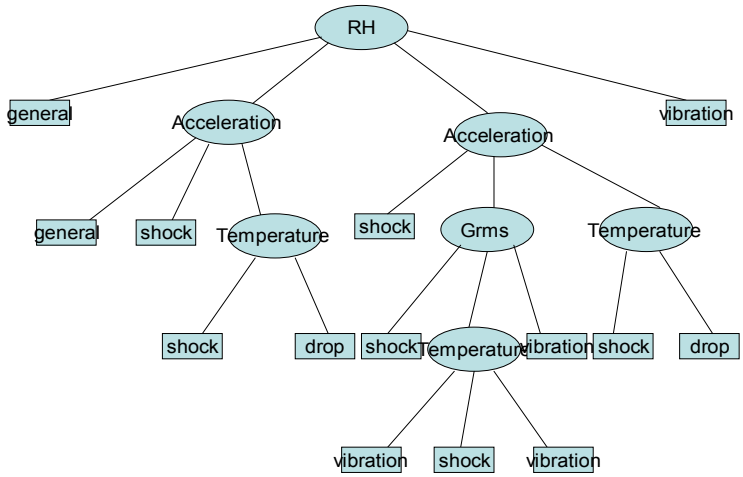

Fig. 1: The original decision tree

Lack of ID3 Algorithm

ID3 algorithm uses non-backtracking top-down strategy to search all of the attribute space. The algorithm establishing the decision tree with a fast classifying speed and a small depth, is simple to achieve. Traditional 1D3 algorithm select an attribute A as the classifying attribute, for it makes information gain Gain (A) maximum. Studies have shown that this approach has disadvantages: the algorithm often are in favor of the attributes with more values, because the weighted sum method makes the classification of instances tend to abandon data tuple with a small amount of data, however the attribute with more values may not be the optimal one, that means firstly selected attribute with the largest information gain according to ID3 algorithm is not so important in reality.

Dynamic Decision Tree

In view of the inadequacies of ID3 algorithm (the method introducing information gain tend to choose the attribute with more values), we adopt “actual information gain” , instead of the information gain. "Actual information gain" methods is to compute a intrinsic information value (Sinfo) to split the original set, considering the scale and quantity of the subset. we can get the "Actual information gain" through Eq. 5:

$$actualGain(A) = [I(s_1, s_2, ..., s_m) - E(A)] / S\inf o \tag{5}$$

Usual Sinfo is just the the number of the subsets, after dividing the original set. Although ,this kind of decision tree will to some extent reduce those situations where we choose the attribute as the splitting attribute just because it will produce more subsets , but this kind of solving methods will inevitably lower the information gain of this attribute. So a technique to balance this dilemma is to introduce a “related Factor” to multiple the number of the subsets ,as Eq.6 and we need Particle Swarm Optimization to get the “related Factor”.

$$S\inf o = v * r\text{elatedF}actor \tag{6}$$

A paper, “No free lunch therems for optimization” , makes a rigorous demonstration of the NFL theory. The theorem points out that, for any questions, any two given algorithms A, B, A, B share the same performance on the average of all problems. However, the main value of NFL theorems lies in its inspiration of research and application the optimization algorithms, it largely reflects the nature of the optimization algorithm. There is no universal algorithm that all the problems can be solved with the best efficiency. The NFL theorem argues that there is a good algorithm in this collection. So,we are able to find a better algorithm in a special field such as the data mining of unknown events during transportation process . Through Particle Swarm Optimization , get a set of related factor optimizing the decision tree at utmost ,and form a most suitable decision tree for this field.

Particle Swarm Optimization

Particle swarm optimization(PSO),a typical swarm intelligence algorithm, was proposed by James Kennedy and Russell Eberhart in 1995. PSO ,similar with genetic algorithm ,is a kind of optimization based on iteration. What is different from GA is PSO does not have crossover and mutation, it achieves one-way flow of information , by following its optimal particle ,thus having a faster convergence rate .

At first generate the initial population, that is produce a set of particle in the feasible solution space, and each particle represents a feasible solution of optimization problem, get a fitness value for each particle according to the corresponding objective function. Each particle motions in the solution space by a speed determining its direction and distance. Typically the particles will follow the current best one, and get the final optimal solution by the iterative search. In each generation, the particle will change following the two extremum, one is the optimal solution of the particle itself so far(pBest), the other the entire population(gBest). Suppose a n-dimensional space is made up of m particles. $X=\{x_1,\ldots,x_i,\ldots,x_m\}^T$, the i-th particle position $x_i=\{x_{i1},x_{i2},\ldots,x_{in}\}^T$, its speed $v_i=\{v_{i1},v_{i2},\ldots,v_{in}\}^T$, the individual extremum $p_{id}=\{p_{i1},p_{i2},\ldots,p_{in}\}^T$ the population extremum $p_{gd}=\{p_{g1},p_{g2},\ldots,p_{gn}\}^T$, in accordance with the principle of following the current optimum particles, the particle x_i will change its speed and position as the following Eq. 7 and Eq. 8.

$$v_{id}^{(t+1)} = v_{id}^{(t)} + c_1 r_1 (p_{id}^{(t)} - x_{id}^{(t)}) + c_2 r_2 (p_{gd}^{(t)} - x_{id}^{(t)}) \tag{7}$$

$$x_{id}^{(t+1)} = x_{id}^{(t)} + v_{id}^{(t+1)} \tag{8}$$

Where d=1，2,…,n，i=1,2,…,m，m is the population size, t is the current evolutionary generation, r1 and r2 are random numbers between 0 and 1, c1 and c2 are Learning Factor or Acceleration Constant. In addition, set V_{max} as speed upper limit to avoid the speed is too big, that is when $V_{id} > V_{max}$,set $V_{id} = V_{max}$, when $V_{id} < -V_{max}$, set $V_{id} = -V_{max}$,. In formula (7) , $v_{id}^{(t)}$is particle velocity previously, $c_1r_1(p_{id}^{(t)} - x_{id}^{(t)})$ is the cognitive section , $c_2r_2(p_{gd}^{(t)} - x_{id}^{(t)})$ is the social section ,representing information sharing and mutual cooperation between the particles.

Algorithm is mainly calculated as follows:

A. initialization , set the learning factor c_1,c_2, the maximum evolution generation T_{max}, the current evolution algebra t = l; generate m particle $x_1,x_2,\ldots,x_m$ randomly in definition space to get population matrix X(t), generate the displacement of each particle randomly $v_1,v_2,\ldots,v_m$ and get the displacement changing matrix V(t).

B. Evaluate the population and calculate the Fitness Value $F(x_i)$ of each particle.

C. Compare the current fitness value $F(x_i)$ of the particle and its history optimal value (pBest) , if $F(x_i)$ is better than pBest, set $F(x_i)$ as pBest , and the current position of the particle as the position pbestX in the space.

D. Compare the current fitness value $F(x_i)$ of the particle and the population optimal value (gBest) , if $F(x_i)$ is better than gBest, set $F(x_i)$ as gBest , and the current position of the particle as the position gbestX .

E. Update the velocity of the particle according to Eq. 8and Eq. 9 ,and generate a new population X(t+1).

F. Check up whether the fitness value has reached a given accuracy or not, If achieved or the number of evolution has reached T_{max} , then end the loop, otherwise t = t +1 , turn B.

What should be mentioned is that it can be classified as local model and global model according to search range of the population . global model means it need to traverse the entire population to get the gBest , otherwise, the local model search the surrounding particle . obviously the global model provide a faster rate of convergence as a sacrifice of robustness. As the local model,the formula changed as Eq. 9:

$$v_{id}^{(t+1)} = v_{id}^{(t)} + c_1r_1(p_{id}^{(t)} - x_{id}^{(t)}) + c_2r_2(p_{id}^{(t)} - x_{id}^{(t)}) \tag{9}$$

Shi et al introduced the inertia weight w into formula(7), then the formula becomes: Eq. 10

$$v_{id}^{(t+1)} = w^t v_{id}^{(t)} + c_1r_1(p_{id}^{(t)} - x_{id}^{(t)}) + c_2r_2(p_{gd}^{(t)} - x_{id}^{(t)}) \tag{10}$$

Obviously, inertia weight w describes the influence of last generation particle on the current. The bigger w is , the stronger the global optimization capability is ,the feebler the local optimization capability is . At the beginning , Shi et al set inertia weight as constant , but through later experiments , they found the dynamic inertia weight leads to better optimization results. At present , a widely used method is 1inearly decreasing weight(LDW) proposed by Shiet al. Eq. 11

$$w^{(t)} = (w_{ini} - w_{fin})(T_{max} - t) / T_{max} + w_{fin} \tag{11}$$

T_{max} represents the maximum number of evolution generation , w_{ini} is the initial inertia weight , w_{fin} inertia weight of maximum evolution generation.

Improved ID3 algorithm based on Particle Swarm Optimization

Get a set of random number within a certain range as the "related factor" ,calculate the "Actual information gain" of each attribute when creating a decision tree with the "related factor" , in the same way ,get n bunches of "related factor", and get n trees , which is used as n particles and the initial population , compute the validity of each decision tree ,which is used as the fitness value of the particle . Reproduce the population according to the fitness value and the Particle Swarm Optimization until the fitness value has reached a given accuracy, or the number of evolution has reached T_{max}.

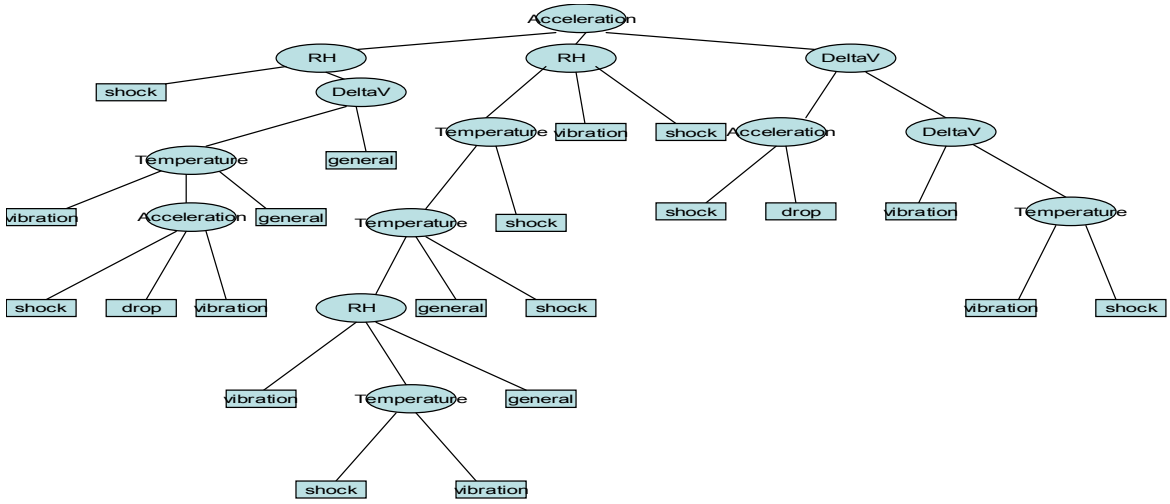

Fig. 3:Improved decision tree

Corresponding algorithm is described as follows:

Improved ID3 algorithm based on the Particle Swarm Optimization:

A . pretreat the original data set S as the root node S.

B. get a set of related factor relatedFactor[n][m] randomly as the n particles, $x_1,x_2,\ldots,x_n$ to generate the population matrix X(t), get a set of displacement randomly $v_1,v_2,\ldots,v_n$ to generate the displacement matrix V(t), set $c_1 = c_2 = 2$ and the current generation t=1 .

C. Calculate the information gain of the attribute C_i, i ∈ {1,2,3,…,m}Eq. 12

$$Gain(C_i) = [I(s_1, s_2, ..., s_m) - E(C_i)] / v * r\text{elatedF}actor \tag{12}$$

D. Repeat C operation, calculate the information gain of the m attributes Gain(C_1), Gain(C_2),…, Gain(C_m), divide the father node into several child nodes according to the attribute with the largest information.

E. duplicate B, C, D operation until all the nodes can not be subdivided so far to get the decision tree T.

F. duplicate, B, C, D, E operation to form N decision trees T_j, (j = 1,2, ..., N) , corresponding to n bunches of related factor relatedFactor[n][m].

G. test the validity (test data set is the same) of T_j decision trees with specified test data and get its validity V_j.

H. repeat B, C, D, F, G operation to obtain the validity of N decision trees, V_1 ,V_2 ,…,V_N,and set pBest[i]= V_i.

I. compare the value V_1 ,V_2 ,…,V_N, and select the maximum value V_m as the gBest.

J. Update the related factor according to equation (10) equation (8) ,and generate the second bunch of decision tree with it . For each tree (i) ,if V_i >pBest[i] , pBest[i]= V_i; select the maximum of the bunch (V_m), if V_m >gBest, gBest= V_m. Set w_{ini}=0.9, w_{fin}=0.4.
K. Repeat J operation until it is reached T_{max},and get the decision tree with gBest as final result.

The improved sample

Mend the formula in the above sample , revise the source code ,and get the following running result. Suppose the number of the particle is 20, that is there are 20 decision trees, and the size of loop is 20 ,so the validity of each decision tree in 20 loops are showed in the Table 1,and the related factor of the last loop are listed in the Fig. 2. Classify and organize the same branch of the decision tree in Fig. 3: improved decision tree

TABLE 1: THE VALIDITY OF EACH DECISION TREE IN 20 LOOPS

generation	pBest	gBest	20 fitness value(validity of the 20 decision tree)										20 fitness value(validity of the 20 decision tree)

Summary

Through the experimental data, it is verified that the introduction of the dynamic decision tree based on Particle Swarm Optimization for the improvement of the validity of traditional ID3 decision tree algorithm is achieved .The validity of the new decision tree is 0.831776 ,which is improved by 21.918% than the old one created by the traditional ID3 algorithm , and we can get a better tree than before .We are able to control the environmental parameters during transportation using of the improved decision tree, in order to achieve the effect of controlling emergencies, prevention, and pretreatment. The only pity is that the robustness need to be enhanced, especially when some parameters was not that suitable, the validity of the decision tree would be badly influenced , and we expect it to be mended as soon as possible .

Keywords: modeling; simulation; component; Petri net.

Abstract: The structure of Petri net model is relative fixed after it is built, so it can't describe dynamic change behavior of real system structure easily. Description formalness, coupling mechanism and simulation method were presented, the dynamic change of Petri net structure in simulation run was realized based on the idea of software component design. The reuse capability of Petri net model is enhanced, integration with other models is convenience and hierarchical modeling mode is realized, and the capability of modeling and simulation of Petri net is improved.

Introduction

Petri net is a description and analysis tool for discrete event systems modeling and simulation, it can describe concurrency, synchronization, resource distribution and other issue easily, has been used in the modeling and simulation of complex systems widely. But Petri net has some shortcomings, for example, its structure is relatively fixed, makes it difficult to describe the dynamic structure changes of actual systems. The variable structure Petri net is introduced to solve this problem by adding dynamic change element such as place, transition and so on. [1, 2, 3]

Component based design method is a software develop method which uses reusable function modules and combines these modules to construct complex software systems. It has used in the field of modeling and simulation domain on account of its good scalability and flexibility. [4,5]We introduced the idea of component based design in Petri net modeling, and researched description formalness, coupling mechanism and simulation method, to realize changeable structure Petri net modeling and simulation.

Component Based Petri Net Model Description

Component based Petri net model is an extension of the basic Petri net model, its model is divided into atomic component Petri net model and composite component Petri net model, atomic component Petri net model is the basis of building simulation model, and it is a encapsulated Petri net, its internal structure shields the outside world, exchanging information through input and output ports with external environment, the composite component Petri net model is combination of atomic component Petri net model by port coupling way. Atomic component Petri net model is described as:

$$PNM=(P,T,I,M_0,Inports,Outports,Atts,Funcs)$$

P is a set of non-empty finite place, T is a set of non-empty finite transition, I is a limited non-empty input arc set which satisfies $I \subseteq P \times T$, O is a limited non-empty output arc set which satisfies $O \subseteq T \times P$, $M_0 : P \to Z^0$ is the initial marking, *Inports* is a input port set, *Outports* is a output port set, *Atts* is a set of attributes which are used to monitor states of model, *Funcs* is a set of interface functions which are used to control the states transition of model. For all $p \in P$, define ${}^*p = \{t \in T | (t,p) \in O\}$, and $p^* = \{t \in T | (p,t) \in I\}$.

Input ports and output ports are special kinds of place to provide information exchange interface, namely:

$$Inports \subseteq P, Outports \subseteq P$$

For the input ports, satisfies：

$\forall p \in Inports, {}^{*}p = \Phi, \quad and \quad p^{*} \neq \Phi$

For the output ports, satisfies：

$\forall p \in Outports, p^{*} = \Phi, \quad and \quad {}^{*}p \neq \Phi$

Two special types of graphics element are extended on the basis of basic Petri nets with graph format “◎", "○,△" , which represent input port and output port respectively, as shown in Figure 1.

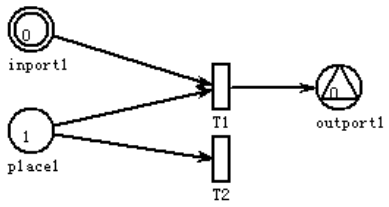

Figure 1 Component Petri net modeling elements

The composite component Petri net model is described as:

CPNM=(PNMS,Inports,Outports,Attr,Func,CR)

PNMS is a set of sub-models , *Inports,Outports,Attr,Func* is defined as the atomic component Petri net model. *CR* is defined the port coupling relationship between models, and satisfies:

$$CR : (M_1, I) \rightarrow (M_2, O) \text{ and}$$

$$I \in Inports(M_1), O \in Outports(M_2), M_1 \neq M_2$$

Port coupling relationship of the model can be divided into three types:

External input coupling: composite model input port is connected to the input port of one or more sub-model.

External output coupling: the sub-model output port connected to the composite model output ports.

The Internal Coupling: the sub-model output port is connected to the input port of the other sub-models.

Port coupling relationship describes token flow path between models, and simulation environment controls message dispatch by port coupling relationship table.

Simulation Method of the Model

Component Petri net model has a hierarchical tree structure and supports hierarchical modeling, as shown in Figure 2.

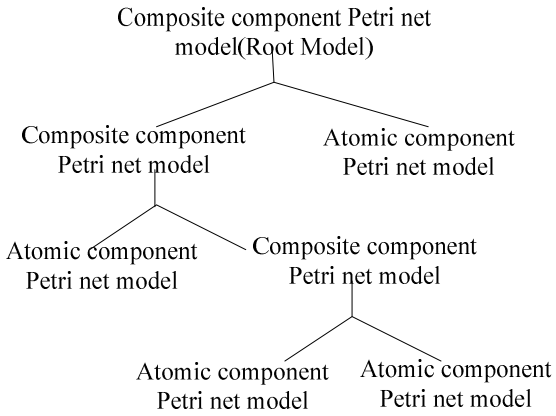

Figure 2 Component Petri net model structure

The operational mechanism of atomic component Petri net is similar to basic Petri net, which is realized by firing of transition, at first we must judge which transition is enabled. for $t \in T$, define ${}^{*}t = \{p \in P | (p,t) \in I\}$, and $t^{*} = \{p \in P | (t,p) \in O\}$. When rule (1) is satisfied, t is enabled.

$$\text{For all } p \in {}^{*}t, M(p) > 0. \qquad (1)$$

After transition is fired, the marking of Petri net will change as rule (2).

$$M'(p)=\begin{cases} M(p)-1, & p\in {}^{*}t \\ M(p)+1, & p\in t^{*} \\ M(p), & p\notin {}^{*}t\cup t^{*} \end{cases} \quad (2)$$

The entire component Petri net model simulation run starts from the top-level model:

Step 1: Scan the sub-model collection $PNMS$ of Root, for M$\in PNMS$, if it is atomic component model, go to step 2, otherwise go to step 3.

Step 2: According to rules (1) and (2), modifies the state of the model, scans its output ports set, removing token from output ports, insert corresponding token to input port of other models according to port coupling relationship table, return to step 1.

Step 3: Replace model Root by M, go to step 1.

Changeable Model Structure Control Mechanism

The design standards of the component Petri net model can be used Active X, CORBA or JavaBeans. We used Microsoft Active X component design specifications, the properties of the model correspond to the attributes of Active X components, the model interface functions correspond to Active X component interfaces.

Simulation environment uses model's interface function to control the dynamic changes of the model structure and model states. The generic interface functions are designed to realize these functions, for example:

- AddObject

Add a Petri net model in the current simulation environment.

- RemoveObject

Remove a Petri net model from the current simulation environment.

- AddPlace

Add a place in the current model.

- RemovePlace

Remove a place from current model.

- AddTransition

Add a transition in the current model.

- RemoveTransition

Remove a transition from the current model.

- AddArc

Add an arc in the current model.

- RemoveArc

Remove an arc from the current model.

The dynamic changes of the structure of Petri nets involves Petri net model dynamic join / leave, Petri network element changes, Petri net model coupling relationship changes. Meanwhile, in order to achieve the reuse of Petri net models, models library is established to provide effective management for model information, port information and attribute information and so on. User can modify the existing models in the model library, and combine them to create a new model, without having to be developed from scratch.

Example Description

Component based Petri net modeling Combines characteristics of basic Petri net modeling with object oriented modeling, and supports top-down or bottom-up analysis, so the establishment of a complex system modeling is rapid. Figure 3 give a sample of an air defense command information system's model architecture.

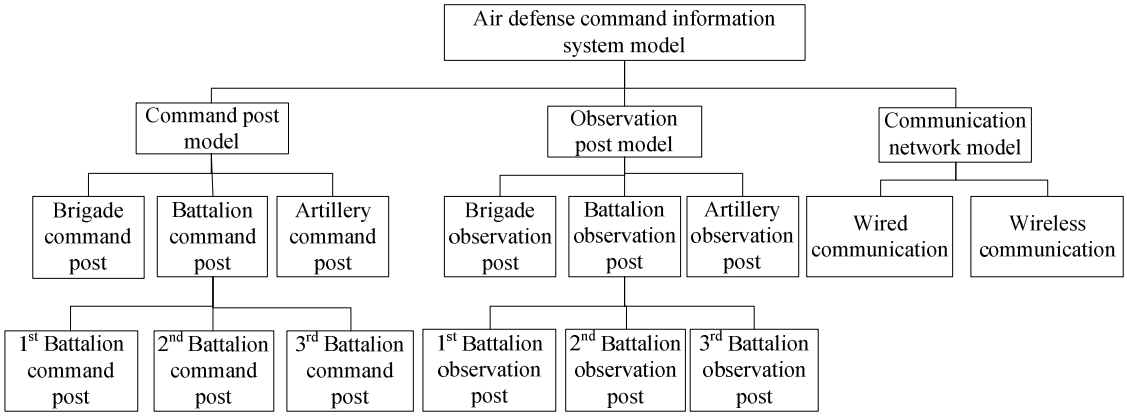

Figure 3 Air defense command information system model architecture

The bottom is atomic components Petri net model, can be constructed by basic Petri net modeling method. For example, atomic components Petri net model of 1st battalion command post is shown in Figure 4 below.

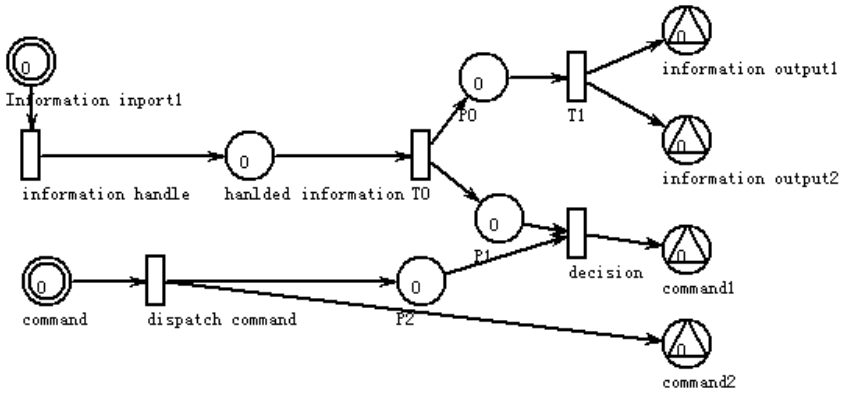

Figure 4 1st battalion command post Petri net model

The Battalion command post model consists of three subordinate battalion command post Petri net model combination(1st,2nd,3rd), port coupled relational table is shown in Table 1.

TABLE 1 BATTALION COMMAND POST MODEL PORT COUPLING RELATIONAL TABLE

Source model	port	Destination model	port	Couple style
1st battalion command post	Information Output 1	battalion command post	Information Output 2	external output coupling
2nd battalion command post	Information Output 1	battalion command post	Information Output 3	external output coupling
1st battalion command post	Information Input 1	battalion command post	Information Input 1	external input coupling
1st battalion command post	Information output 2	3rd battalion command post	Information Input 2	Internal Coupling
…	…	…	…	…

While simulation running, the simulation environment will dynamically create the model, and add it to simulation environment and interact with other models, it also can be removed from simulation environment to realize dynamic changes of model structure.

Summary

The combination of components based software design method with Petri net supports the hierarchical modeling of Petri net, facilitates reuse of Petri net. Component interface control mechanisms realizes dynamic changes of the structure of Petri net during simulation, Meanwhile, models can be embedded into other simulation environment by regulating the port coupling relationship table and interface functions to achieve interoperability with other kinds models.

qilanmail@163.com

Keywords: square residue, the Mangoldt function,asymptotic formula.

Abstract: Let n be a positive integer, S(n) denote the square residue. This paper is mainly to study the hybrid mean value properties of the square residue S(n) and the Mangoldt function, and give an interesting asymptotic formula.

Introduction and result

For any positive integer n, let $n = p_1^{\alpha_1} p_2^{\alpha_2} \cdots p_r^{\alpha_r}$ is the factorization of n into prime powers, where $p_1, p_2, \cdots, p_r$ are distinct prime numbers and $\alpha_i \geq 1$. The square residue $S(n)$ is denoted as $S(n) = p_1 p_2 \cdots p_r$ .For example, $S(2) = 2, S(3) = 3, S(4) = 2, S(5) = 5, S(6) = 6, S(7) = 7, S(8) = 2, \cdots$.

In problem 63 of reference [1], Professor F.Smarandache suggested that we study the properties of the square residue $S(n)$, many scholars had studied before, and obtain some interesting results[2-6].For example, Gou Su[2] presented the asymptotic formula

$$\sum_{n \leq x} d(S(n)) = \frac{6}{\pi^2}[x \ln x + (2\gamma - 1)x] + O(x^{\frac{1}{2}} \ln^2 x),$$

where $d(n)$ is Dirichlet divisor function, γ is Euler constant.

Wang Ming-jun[3] proved the the asymptotic formula

$$\sum_{n \leq x} \sigma(S(n)) = \frac{3x^2}{\pi^2} \prod_p (1 + \frac{1}{p^2 - 1}) + O(x^{\frac{3}{2}+\varepsilon}).$$

Ge Dan and He Yan-feng[4] gived some mean value formulas by analytic method, the one of them is

$$\sum_{n\le x} d(k,S(n)) = x\prod_{p|k}(1+\frac{1}{p}) + O(x^{\frac{1}{2}+\varepsilon}),$$

where $k,n \in N$, $(k,S(n))$ denotes the common divisor of k and $S(n)$.

The Mangoldt function is the famous number theory function, it seems no one know the relation between the square residue and Mangold function before.

In the paper, we shall use the elementary method to study the hybrid mean value of the square residue $S(n)$ and the Mangoldt function , and give an interesting asymptotic formula. That is the following:

Theorem 1 Let $x \ge 2$, we have the asymptotic formula

$$\sum_{n\le x} \Lambda_1(n)S(n) = \frac{1}{2}x^2 + O(\frac{x^2}{\log x}),$$

where

$$\Lambda_1(\mathrm{n}) = \begin{cases} \log \mathrm{p}, & \text{if n is a prime p;} \\ 0, & \text{otherwise.} \end{cases}$$

Theorem 2 Let $x \ge 2$, we have the asymptotic formula

$$\sum_{n\le x} \Lambda(n)S(n) = \frac{1}{2}x^2 + O(\frac{x^2}{\log x}),$$

where $\Lambda(n)$ is the Mangoldt function.

The Proof of theorem

In this section, we will complete the proofs of the theorems. According the definition of the square residue $S(n)$, the function $S(n)$ is a multiplicative function, obviously we have $S(p^k) = p$.

Let

$$\mathrm{a(n)} = \begin{cases} 1, & \text{if n is a prime ;} \\ 0, & \text{otherwise,} \end{cases}$$

We have

$$a(n) = \pi(x) = \frac{x}{\log x} + O(\frac{x^2}{\log x}).$$

By Abel's identity[5], we have

$$\sum_{n\le x} \Lambda_1(n)S(n) = \sum_{p\le x} p\log p = \sum_{n\le x} a(n)n\log n$$

$$= \pi(x) \cdot x \log x - \int_2^x \pi(t)(\log t + 1)\,\mathrm{d}\,t$$

$$= x^2 + O(\frac{x^2}{\log x}) - \int_2^x (t + \frac{t}{\log t} + O(\frac{t \log t + t}{\log^2 t}))\,\mathrm{d}\,t$$

$$= \frac{1}{2}x^2 + O(\frac{x^2}{\log x}).$$

This proves Theorem 1.
Using the same method,we may immediately get:

$$\sum_{n \le x} \Lambda(n) S(n) = \sum_{p^k \le x} p \log p$$

$$= \sum_{p \le x} p \log p + \sum_{\substack{p^k \le x \\ k \ge 2}} p \log p,$$

noting that $p^k \le x$ and $k \ge 2$,we get $p \le \sqrt{x}$,

then

$$\sum_{\substack{p^k \le x \\ k \ge 2}} p \log p = \sum_{p \le \sqrt{x}} p \log p \sum_{k=2}^{[\frac{\log x}{\log p}]} 1 \le \sum_{p \le \sqrt{x}} p \log p \frac{\log x}{\log p} \le x^{\frac{3}{2}} \log x,$$

so we have

$$\sum_{n \le x} \Lambda(n) S(n) = \frac{1}{2}x^2 + O(\frac{x^2}{\log x}).$$

Thus we have complete the proof of theorem 2.

Keywords: feature extraction, moment invariant, Harris corner, image registration

Abstract. To match two or more images originated from the same scenario, a new fast automatic registration algorithm based on sparse feature point extraction is proposed. At the first step, the improved Harris corner detection algorithm is used to get two sets of feature points from the reference image and registration image. Second, a group of sparse feature points are selected from the reference image set as initial control points. Then, the corresponding matching points in the registration image set are searched based on local moment invariant similarity detection. Experimental results demonstrate that this method is fast and efficient.

Introduction

For different sensors the physical characteristics or imaging mechanism widely varied. There may be a rotation, translation and scaling existed in two or more images originated from same scenario. So it is necessary for image registration before the pixel-level image fusion. Image registration is the process in which two or more images originated from same scenario collected by different sensors or in different times are matched or combined. During the last decades, image registration has undergone rapid development and growing amount and diversity of methods and techniques [1-6]. In 1992 Brown published his comprehensive survey of image registration methods in his work. In order to solve the problems discussed above, in this paper a new fast automatic registration algorithm based on sparse feature points is proposed.

Sparse Feature Point Extraction

How to accurately extract the feature points is a key issue to image fusion algorithms. In [7] Schmid et al. take repeatability rate and information degree as performance index to evaluate the point detection algorithm, where the results from evaluation showed that Harris corner extraction algorithm can achieve the optimal effects. Based on the analysis to traditional feature point extraction algorithms, Schmid proposed an improved Harris corner extraction algorithm in his paper. In our work this algorithm is used for extracting the Harris corner of the reference image and registration image as the initial matching set.

The traditional Harris corner extraction algorithms use the autocorrelation function to judge the signal changes in horizontal and vertical direction in image. If the obvious changes take place in two directions, this point will be considered as a feature corner. The autocorrelation function can be represented by following matrix:

$$A = e^{-\frac{x^2+y^2}{2\sigma^2}} \otimes \begin{bmatrix} J_x^2 & J_x J_y \\ J_x J_y & J_y^2 \end{bmatrix} \tag{1}$$

where J define a grey image; J_x and J_y designate differential capacity in two directions respectively. Differential matrix is weighted with standard Gaussian parameter $\sigma = 2$.

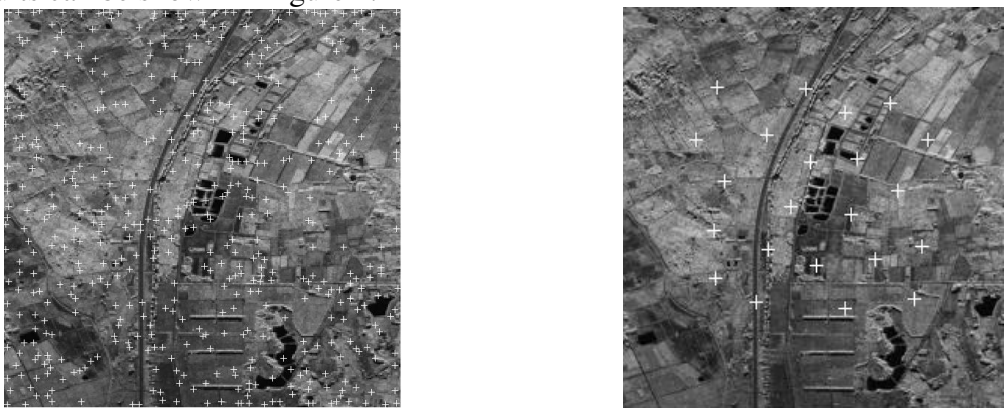
In typical methods the differential matrix in Eq.1 can be obtained by calculating the convolution of J and template $[-2,-1,0,1,2]$. According to autocorrelation function, if the eigenvalue of the matrix corresponding to current point is very large, we consider this point as a corner. In order to avoid extracting eigenvalue of each point from matrix A, the growth of information G is used to judge whether the change of current point signal in two directions is obvious or not. The variable G is defined by following equation:

$$G = \det(A) - \alpha[\text{trace}(A)]^2 \tag{2}$$

where det(·) denotes the determinant operation of a matrix and trace(·) denotes the trace of a matrix. In virtue of analysis to Harris corner in [7], for the images in same scenario, no matter how large the rotation angle is, the repeating extraction rate of corners can reach up to 90%. For a rich textured SAR image, the extracted feature corners with Harris algorithm can reach a large number, which make the computational cost is very large. In order to decrease the computational cost, we usually choose a group of separated points with a certain distance (i.e. $d = 30$ pixels) as initial points of interest in feature point set of reference image. By this way the Harris corner with the largest value in growth rate in image can be determined first; then the sparse feature point set is selected as initial control points by comparing distance d. The detailed selection process of sparse feature points is as follows:

Step 1: Filtering the reference image and registration image using GF (Gaussian filter) with parameter $\sigma = 0.85$;

Step 2: Calculating the growth of information with Eq.2;



Step 3: Using template of 3×3 to suppress non-maximum points;

Step 4: Determining the feature corners using experimental threshold;

Step 5: Choosing the information growth maximum points in feature corner set;

Step 6: Selecting n initial feature points according to sparse distance d.

The results can be shown in Figure 1.

Fig. 1 (a) Image with Harris corner extraction and (b) Image with sparse feature points selection

Bidirectional Moment Invariant Registration Algorithm (BMIRA)

After obtaining the sparse feature points, we use a similarity decision mechanism for searching the homonymous control points in registration image. Because there are a large amount problems existed in traditional template matching methods such as slow matching speed, noise sensitive, in our algorithm we choose the moment invariants for searching the homonymous control points, which can not be affected by rotation, translation, scaling.

Define the $p+q$ order moment of the image $f(x,y)$:

$$m_{pq} = \sum_{(x,y)} x^p y^q f(x,y) \tag{3}$$

and the $p+q$ order central moment of $f(x,y)$:

$$\mu_{pq}=\sum_{(x,y)}(x-x_t)^p(y-y_t)^q f(x,y) \tag{4}$$

where $x_t=\frac{m_{10}}{m_{00}}$ and $y_t=\frac{m_{01}}{m_{00}}$ is barycentric coordinate of $f(x,y)$. The normalized central moment of $f(x,y)$ can be represented by

$$v_{pq}=\frac{\mu_{pq}}{\mu_{00}^{\gamma}},\gamma=\frac{p+q}{2}+1,\ p+q=2,3,\cdots \tag{5}$$

Multiple moment invariants can be obtained by using normalized central moments. Through the experiment, the following group of moment invariants is selected with better effects as well as certain robustness in application of image recognition and registration:

$$\kappa_1=(v_{30}-3v_{12})^2+(3v_{21}-v_{03})^2 \tag{6}$$

$$\kappa_2=(v_{30}+v_{12})^2+(v_{21}+v_{03})^2 \tag{7}$$

$$\begin{aligned}\kappa_3=&(v_{30}-3v_{12})(v_{30}+v_{12})\left[(v_{30}+v_{12})^2-3(v_{21}+v_{03})^2\right]\\&+(3v_{21}-v_{03})(v_{21}+v_{03})\left[3(v_{30}+v_{12})^2-(v_{21}+v_{03})^2\right]\end{aligned} \tag{8}$$

$$\begin{aligned}\kappa_4=&(3v_{21}-v_{03})(v_{30}+v_{12})\left[(v_{30}+v_{12})^2-3(v_{21}+v_{03})^2\right]\\&-(v_{30}-3v_{12})(v_{21}+v_{03})\left[3(v_{30}+v_{12})^2-(v_{21}+v_{03})^2\right]\end{aligned} \tag{9}$$

$$\begin{aligned}\kappa_5=&\left[v_{50}-10v_{32}+5v_{14}-10(v_{20}v_{30}-v_{30}v_{02}-3v_{12}v_{20}+3v_{12}v_{02}-6v_{11}v_{21}+2v_{11}v_{03})\right]^2\\&+\left[v_{05}-10v_{23}+5v_{41}-10(v_{02}v_{03}-v_{03}v_{20}-3v_{21}v_{02}+3v_{21}v_{20}-6v_{11}v_{12}+2v_{11}v_{30})\right]^2\end{aligned} \tag{10}$$

For using Euclidean criterion to measure the similarity between points easily, we take the absolute value of the moment invariants $\kappa=(\kappa_1,\kappa_2,\cdots,\kappa_5)$ after logarithmic transformation, from which the local characteristic matrix $A(r)$ for current point is derived:

$$A(r)=\left(\mathrm{abs}\left(\log(\kappa_1)\right),...,\mathrm{abs}\left(\log(\kappa_5)\right)\right) \tag{11}$$

According to the description above, the time consumption mainly causes by comparing the similarity of feature points in reference image and registration image. The flow chart of the algorithm based on Bidirectional moment invariant of sparse feature points is demonstrated as Figure 2.

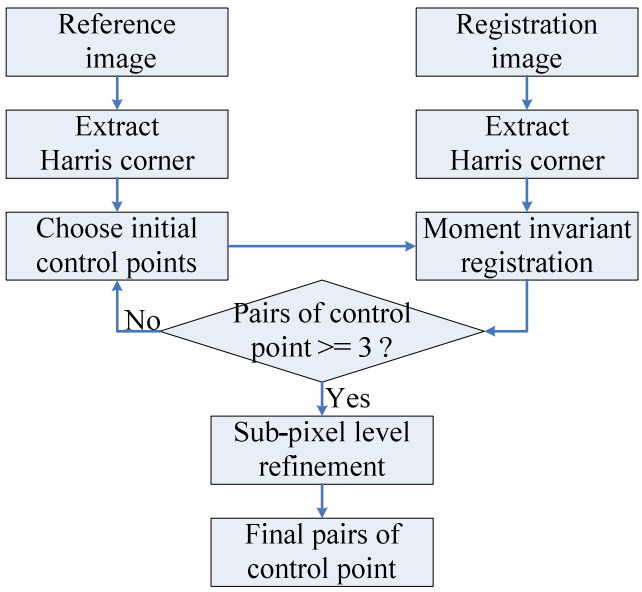

Fig. 2 Flow chart of the bidirectional moment invariant algorithm

Finally, we use the method in [63] to determine the position coordinates of the pair of control point in registration image. Given the matching template plane function $M(x, y)$, the registration image is located in (x_s, y_s), the coordinates of the peak can be calculated using following formula:

$$x = x_s - \frac{1}{2} + \frac{M(x_s, y_s) - M(x_s - 1, y_s)}{2M(x_s, y_s) - M(x_s - 1, y_s) - M(x_s + 1, y_s)} \tag{12}$$

$$y = y_s - \frac{1}{2} + \frac{M(x_s, y_s) - M(x_s, y_s - 1)}{2M(x_s, y_s) - M(x_s, y_s - 1) - M(x_s, y_s + 1)} \tag{13}$$

Experiment and Results Analysis

To demonstrate the operation of the feature extraction algorithm proposed here, and compare its performance with other classic algorithms, in this section we provide a simple registration example for SAR image in Fig.1. The computer configuration is as follows. Processor is Pentium IV 2GHz, Memory 512Mbit, and the operation system is Windows XP. The value of α is 0.06. Table 1 shows the performance evaluation for three algorithms.

Table 1 Performance evaluation for three algorithms

Registration Algorithm	Transform Parameters $(\Delta\theta, \Delta x, \Delta y)$	Time Consumption(s)
SIFT	(162.0124, 0.4516, -0.5731)	35
Manual	(172.1065, 1.2307, 1.2612)	16
BMIRA	(161.5479, -0.0342, 0.4098)	7

Summary

To match the similar band SAR images, a new fast automatic registration algorithm based on sparse feature points is proposed. At the first step, the improved Harris corner detector algorithm is used to get two sets of feature points from the reference and sensed images. At the second step, a group of sparse feature points are selected from the reference image set as initial control points. Then, the corresponding match points in the sensed image set are found based on local moment invariant similarity detection. Experimental results demonstrate that this method is fast and efficient.

Keywords: movement tracking, mitral valve, annulus

Abstract. Clinical diagnosis and therapy planning are increasingly often supported by 3D imaging modalities. Visual and quantitative evaluation of the valve is an important step in the clinical workflow according to experts as knowledge about mitral morphology and dynamics is crucial for interventional planning. We consider optimal matching of the annulus curves as sub-manifolds by a variational approach based on diffeomorphic transformations.The performance of the algorithm is illustrated by numerical results for examples from medical image analysis.

Introduction

The mitral valve is a dual-flap valve in the heart that lies between the left atrium (LA) and the left ventricle (LV)[1]. Disorders of the mitral valve are the second most frequent heart problems, cumulating 14 percent of total number of deaths caused by valvular heart disease each year in the United States and require elaborate clinical management. Visual and quantitative evaluation of the valve is an important step in the clinical workflow according to experts as knowledge about mitral morphology and dynamics is crucial for interventional planning .

We consider optimal matching of sub-manifolds (annulus curves in this paper) by a variational approach based on diffeomorphic transformations[2-6]. In an abstract setting, the optimal matching is formulated as a minimization problem involving actions of diffeomorphisms. The objective functional consists of two parts measuring the elastic energy of the dynamically deformed sub-manifolds and the quality of the matching.

Method

Cubic B-spline Function

As an important mathematical tool to be used in this paper, cubic B-spline function was introduced here firstly. For a spline of degree n, each one of these basic polynomials has degree n, which would suggest that we need n+1coefficients to describe each piece. However, there is an additional smoothness constraint that imposes the continuity of the spline and its derivatives up to order n-1 at the knots, so that, effectively, there is only one degree of freedom per basic polynomial. Here, we will only consider splines with uniform knots and unit spacing, which can be uniquely characterized in terms of a B-spline expansion

$$s(x) = \sum_{k \in Z} c(k) \beta^n (x - k) \tag{1}$$

which involves the integer shifts of the central B-plines of degree n denoted by $\beta^n(x)$; the parameters of the model are the B-spline coefficients c(k). B-splines, defined below, are symmetric, bell-shaped functions constructed from the (n+1)fold convolution of a rectangular pulse $\beta^0(x)$

$$\beta^0(x)=\begin{cases}1, & -1/2<x<1/2\\ 1/2, & |x|=1/2\\ 0, & otherwise\end{cases} \tag{2}$$

$$\beta^n(x)=\underbrace{\beta^0(x)*\beta^0(x)*\cdots\beta^0(x)}_{(n+1)times} \tag{3}$$

The family of B-splines of degree 3 (cubic B-splines) is shown in figure 1. Since the B-spline model is linear, studying the properties of the basic atoms can tell us a lot about splines in general. Thanks to this representation, each spline is unambiguously characterized by its sequence of B-spline coefficients c(k), which has the convenient structure of a discrete signal, even though the underlying model is continuous.

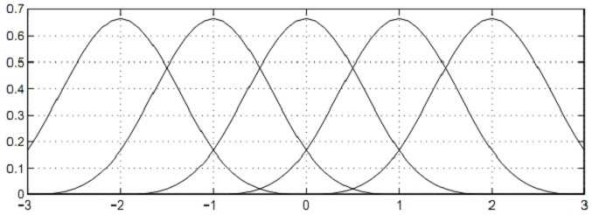

Fig. 1 Cubic B-splines

Shape Matching

The notion of matching requires definition of a good distance among 3D sub-manifolds in R^3. We also consider deformations of R^3, such deformations will form a group G of diffeomorphisms $F:R^3\to R^3$.

Let us consider a diffeomorphism $F:R^3\to R^3$, i.e. $x\in R^3$, $F(x)\in R^3$, reference and target curves are denoted by γ and φ respectively. The reference curve γ is deformed by F to F(γ). The goal is to find F such that φ and F(γ) be close, i.e. the distance between two curves, dist(φ, F ◦ γ), to be small. We also want the deformation to be small. The magnitude of a deformation is determined by the energy of corresponded diffeomorphism. The problem is to find a diffeomorphism F which minimizes the following objective functional

$$J=\lambda\cdot Energy(F)+dist^2(\phi,F\circ\gamma) \tag{4}$$

The first is the regularization term. The positive parameter λ is a measure of regularity of a minimizer. When $\lambda=0$ there a lot of solutions are expected. As λ is positive and approaches zero, the solution F becomes less smooth, but the distance decreases and the curves are better matching.

At point x_t an infinitesimal deformation $V_t(x_t)\in R^3$ is a rate of change of x_t with respect to t. Then the relation between the velocity V_t and the diffeomorphism F_t can be described by the following ODE equation system

$$\begin{cases}dF_t/dt=V_t(F_t(x))\\ F_0(x)=x, \quad \forall x\end{cases} \tag{5}$$

Initialization

Between consecutive instances, the computation was initialized by affine transform. Given B(i) as the set of selected key points at time t_i, where $t_1=0,\cdots,t_p=1$. We solve:

$$B(i+1)=T_i[B(i)], \quad i=1,\cdots,p-1 \tag{6}$$

Where T_i is affine transform, then the initial trajectory was generated by:

$$\begin{aligned} &S(1) = S_0 \\ &S(2) = T_1[S(1)] \\ &\cdots \\ &S(p) = T_{p-1}[S(p-1)] \end{aligned} \tag{7}$$

To solve (6), define

$$B(i) = [X_1 \cdots X_N], \quad X_i = [x_1^i x_2^i x_3^i]^T \tag{8}$$

$$B(i+1) = [Y_1 \cdots Y_N], \quad Y_i = [y_1^i y_2^i y_3^i]^T \tag{9}$$

Suppose

$$T_i(X) = AX + b = \begin{pmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{pmatrix} X + b \tag{10}$$

We solve it by minimization of least square error, in which the error is

$$E(A,b) = \sum_{i=1}^{N} \| Y_i - AX_i - b \|^2 = \sum_{i=1}^{N} \sum_{i=1}^{3} (y_j^i - a_{j1}x_1^i - a_{j2}x_2^i - a_{j3}x_3^i - b_j)^2 \tag{11}$$

Take derivative of it, we have

$$\begin{aligned} 0 = \frac{dE(A,b)}{da_{jk}} &= \sum_{i=1}^{N} x_k^i (y_j^i - a_{j1}x_1^i - a_{j2}x_2^i - a_{j3}x_3^i - b_j) \\ &= \alpha_k a_{j1} + \beta_k a_{j2} + \gamma_k a_{j3} + \varepsilon_k b_j + \delta_{jk} \\ 0 = \frac{dE(A,b)}{db_j} &= \sum_{i=1}^{N} (y_j^i - a_{j1}x_1^i - a_{j2}x_2^i - a_{j3}x_3^i - b_j) \\ &= \varepsilon_1 a_{j1} + \varepsilon_2 a_{j2} + \varepsilon_3 a_{j3} + \sum_{i=1}^{N} y_j^i - N b_j \end{aligned} \tag{12}$$

Where

$$\alpha_k = -\sum_{i=1}^{N} x_k^i x_1^i, \beta_k = -\sum_{i=1}^{N} x_k^i x_2^i, \gamma_k = -\sum_{i=1}^{N} x_k^i x_3^i, \varepsilon_k = -\sum_{i=1}^{N} x_k^i, \delta_{jk} = -\sum_{i=1}^{N} x_k^i y_j^i \tag{13}$$

After further derivation we can get

$$\begin{aligned} &A = \Delta * (M^{-1})^T \\ &b = \frac{1}{N} A\varepsilon - \frac{1}{N} \eta \end{aligned} \tag{14}$$

Where

$$\Delta = YX' + \frac{1}{N} \eta \varepsilon^T, \quad \eta = -\sum_{i=1}^{N} Y_i, \quad \varepsilon = -\sum_{i=1}^{N} X_i \tag{15}$$

Numerical Tracking

In the computation below, we use the previous techniques to numerically construct the diffeomorphic flows roughly approximating the dynamic deformations between multiple 3D-snapshots of the human mitral valve annulus. The given snapshots are modeled by parametrized closed curves in R^3 for the mitral annulus: firstly a few points on the mitral valve annulus were tagged by experienced physicians at different time instances, then the cubic B-spline functions were applied to perform the interpolation on these tagging points to generate continuous annulus curves. For the annulus, we have a series of given snapshots, and we focus on two annulus snapshots, we define the first annulus as the reference annulus (or the beginning moment, identified as red in figure 2), and the other as the target annulus (or the end moment, identified as blue in figure 2), the computed movement of the annulus at the three intermediate moments are plotted in figure 2 as yellow curves.

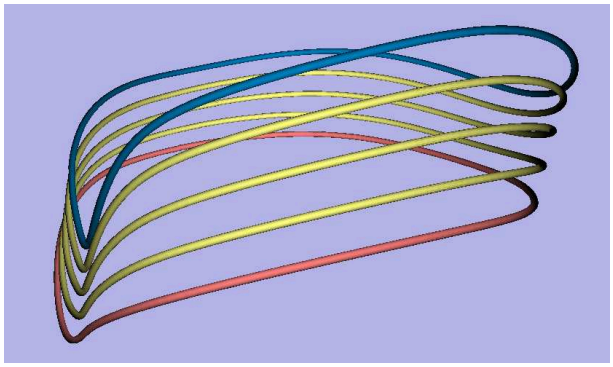

Fig. 2 Computed Mitral Valve Annulus Movement

Summary

Clinical diagnosis and therapy planning are increasingly often supported by 3D imaging modalities. Visual and quantitative evaluation of the mitral valve annulus is an important step in the clinical work. In this paper, we consider optimal matching of the annulus curves as sub-manifolds by a variational approach based on diffeomorphic transformations.The performance of the algorithm is illustrated by numerical results for examples from medical image analysis.

Keywords: Monte Carlo, Ising Model, magnetization intensity

Abstract: Simulating Ising model to calculate magnetization intensity by Monte Carlo method. The Ising model was introduced simply, sampled importantly, and calculated with programming. It shows the dependency relationship between the magnetization intensity and the size of dot-square line in different temperatures for Ising model. It cans edulcorate the approximation of analytic method by computer simulating. It obtains a method to appraise a model right or wrong by comparing the model and the experimental data.

Foreword

It is a usual tool to much science to computer simulation. It is for many reasons to simulate by computer to physical system. Computer simulation can edulcorate the approximation of analytic model[1]. A kind of simulation must be shown to resolve a problem by analytic method usually, such as approximation of mean field. It can study problems analytic method can not resolve by computer simulation.

It obtains the standard to compare all kinds of approximate theories for the complex system can be studied by computer simulation method. At the same time, it allows to compare the model and experimental data for computer simulation method, and it find a way to evaluate the model right or wrong[2,3]. The starting point to a computer simulation is a determinate model of a physical system, and calculate the properties of the physical system, those properties or observable values can get by averaging from someone sample space. It is calculated by Mote Carlo method to the magnetization intensity of Ising Model in this article.

Brief of Model

The system that shows order to disorder phase transition can be studied by equilibrium statistical mechanics. It is the simplest example that dot matrix constituted by two different matters, A and B (Fig.1) . It suppose that there is only interaction nearest, and uses V_{AB} to figure the interaction energy between A and B, V_{AA} and V_{BB} figure the interaction energy between A and A, B and B. First, it think the condition that the system is at T=0K.

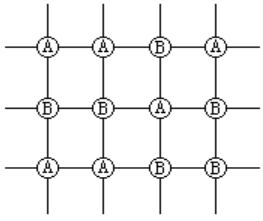

Fig.1 Every Square-dot Should be A or B in two Dimensions Matrix

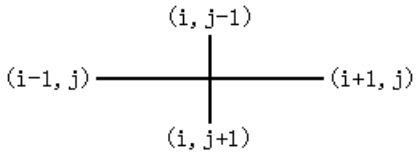
①If $V_{AB} > 1/2 (V_{AA} + V_{BB})$, then all of A are adjacent to each other, and all of B are neighbor. It is beneficial to this combination form to energy. The whole dot matrix was separated into areas under this condition, some include A only, and the others include B only.

②If $V_{AB} > 1/2 (V_{AA} + V_{BB})$, then it is beneficial that A and B is nearest each other to energy. So A and B will be Alternating arrangement in dot matrix.

Both of above two conditions are ordered state. If temperature is raised, heat energy K_B will impel randomization of position of A and B. The system will *melt* at a special degree. The whole system will be out-of-order completely when temperature rising. The form of partition function to this kind of system should be as follows.



$$Z_N(T) = \sum \exp(-\beta \sum V_{ij})$$

It is called Ising model to the mathematical model of this kind of system. It defines as below. $G=L^d$ is a dot-square of d-dimension. There is a spinning S_i in every mount point i, it can be +1 or -1. Every spinning can interact by the exchange coupling energy J. And an external magnetic field H can be exist, Hamiltonian for the system be as follows.

$$\Re = -J \sum_{i,j} S_i S_j + \mu H \sum_i S_i$$

The Sample of Two Dimensions Ising Model

To study this problem in two dimensions, it should think about Hamiltonian of Ising Model $\Re = -J \sum_{(i,j)} S_i S_j$, J means exchange interaction for nearest neighbor mount point. It can be positive, ferromagnetism, and negative, antiferromagnetism. The variable S means a spinning, can be +1 or -1. The symbol <i,j> represent the four nearest neighbor mount point (i,j) for limitation of simple square.

The x represents a spinning. It produces a Markov chain $x_0, x_1, \ldots\ldots, x_n$ to make configuration $x_{(+)}$ only depend on its configuration $x_{(i)}$ ago. The probability from x_i to x_{i+1} can get by a transition probability $W(x_{i+1}|x_i)$.

The transition means that all state $x_0, x_1, \ldots\ldots, x_n$ should be Boltzmann distribution.

$$P(x) \propto \exp\left(-\frac{\Re(x)}{K_B T}\right)$$

How does it choose transition probability to ensure the state distribution following the Boltzmann law? If limitation to conduct the reverse single spinning S_i, it suppose that energy will lose when a spinning S_i reverse to $-S_i$. Because it always is ground state of model, or close to, so it should is accepted as probability is 1. In condition of energy exchange $\Delta\Re = \Re(X^{new}) - \Re(X^{old})$ is negative, $W(x_{new}|x_{old})=1$. But it must fall into a minimum energy in some areas. The change of

energy increasing can be accepted to avoid this thing. However the change of increasing much energy does not happen so much, so the probability is very low. On the contrary, the energy change is little, means the energy of new configuration is similar with the old configuration, then it is high probability to allow the change. The minimum energy in some areas can be broken away from to reach further.

How does it choose the transition in the condition of the energy change $\Delta\Re$ is positive? A choice looks reasonable and provable accurately is as follows.

$$W(X_{i+1}|X_i) = \min[1, \exp(-\frac{\Delta\Re}{K_B T})]$$

That is called Metropolis function. But it is not the only choice to transition probability. There are other choices, such as Glauber function$\{\frac{1}{2}[1-\tanh(\Delta \hat{A}/2K_B T)]\}$。

It built transition probability to single reverse spinning. All spin has only a chance of reversing direction at once, then a scanning is completed. A scanning is called spinning-Monte Carlo step. short for MCS.

There are several probable method to scan whole dot-square once. The scanning means that scan from the beginning to the end regularly. An other probable method is that the accessing mount points are sampled randomly. If the attempt times are equal to the count of mount point, it means a Monte Carlo step is complete. Some mount point maybe think about some times in a Mento Carlo step, and some others are not including. If the random numbers themselves have no problem in average, every mount point gets a reverse chance.

Someone initial configuration S_0 must be used in order to start important sample, and then new states are generated continuously. Which should initial spinning configuration be chosen? It supposes that the average properties of Ising model are studied in some temperature, such as magnetization and magnetic susceptibility. And it suppose that the spinning configuration start randomly, and not a complete order. Now the system is made evolutions in time by function, such as Metropolis function. The hardening is carried on indeed, it get into order area from out-of-order in phase diagram. It will take very long time to build up a balance state. The excess energy must be removed before the balance state established.

Now it is back to talk about transition probability. The configuration x_{i+1} is not different with x_i obviously. It allows single particle spinning but not many particles, because the last will cause two configurations further in phase space. The state order can be looked as the track in the phase space. It must be relative between the neighbor configurations from this point. The n_d states must be abandoned in two sample point in order to get a unbiased statistical sampling for state. It based on the temperature that how many stats must be abandon, and based on conservation law. See it in algorithm1.

Algorithm 1 Ising moel

```
                ( * dot-square initial*)
          DO    10    I=1，L
          DO     10    J=1，L
          LATTICE（I, J）=-1
10        CONTINUE
           COUNT=0
```

```
DO    20    MCS=1，MCSMAX
        GENERATE-ONE-STEP;          （Make a scanning）
        IF（MCS.GE.Nδ）THEN
        COUNT=COUNT+1
        END IF
        IF（COUNT=Nδ）THEN
       COUNT=0
        DO-ANALYSIS;                （Analyze）
        END IF
20      CONTINUE
        END
```

After preparation of the acknowledge, it need to talk about the core part of important sample algorithm of Ising model, GENERATE-ONE-STEP in algorithm 1 (make a scanning). Designing transition probability make attempt to reverse all spins always. It is a Monte Carlo step. A new configuration can be gotten from last configuration after a Monte Carlo step. So first step is algorithm 2, L is size of dot-square in it.

```
Algorithm 2     GENERATE-ONE-STEP
DO     10     I=1，L
    DO    10     J=1，L
      COMPUTE-THE-ENERGY-DIFFERENCE; (calculate energy difference)
          DECIDE-TO-FLIP-OR-NOT;          （decide reverse or not）
10  CONTINUE
```

It is nor necessary to calculate linear function with every reversing spin. There are five probable values for energy difference. The function can calculate in advance and deposit in a array to seek quickly. The energy difference is follows.

$$\Delta\Re = 2S_i \frac{J}{K_B T} \sum_{nn(j)} S_i$$

The symbol nn(j) means four nearest neighbors of central spin in function.

There is a problem only. The last title calculation of energy difference must be solved. It is a choice as same as decision of percolation, and must choose one from different border conditions. The key of every spin can not hang alone at the edge of square. The spins must interact with the nearest neighbor. The periodic edge condition is chosen here.

Using remainder function is a method to realize periodic edge condition. At the edge of square, i is 1 or L or j is 1 or L in central spin (I,j), the nearest neighbor can be calculated as follows.

```
ip1=i＋1   （mod L）          im1=i－1   （mod L）
jp1=j＋1     （mod L）          jm1=j－1   （mod L）
```

This algorithm spends very long time. Every calculation of remainder function has several math calculations, time is the key. The innermost layer of the circle must be made up of the less times of math calculation. A table is used to solve that. It need two tables in fact, one for “add” calculation, one for “subtract” calculation (algorithm 3).

Algorithm 3 The table instead of remainder function

```
REAL  IP（L），IM（L）
      DO    10    I=1，L
      IP（I）=I+1
      IM（I）=I+1
      IP（L）=1
      IM（1）=L
10    CONTINUE
```

The algorithm of important sample for two dimensions has finished. All most parts have designed. It should affirm the phase transition point in simple dot-square for two dimensions, J/K_BT_C. Of course, it has known accurately to the analytical result for the two dimensions Ising model. It is a chance to judge the job good or not to data analysis. The phase transition point for limited system will be dim. The effect of limited size is relative with the edge condition. It is different result between the order parameter and the magnetization to the simple sample for the percolation. Same to the phase transition causing by heating.

Conclusions

It shows the relationship between the magnetization and the size of dot-square line for two dimensions Ising model in fig.2. It obviously seen that the magnetization depends on the size of dot-square. The effect is most remarkable near the critical temperature. At the low temperature, T is more lower than T_c, the effect of the size of dot-square is not sensitive to the result. The magnetization there converge quickly to the true limitation of thermodynamics. Although it does not exist self magnetic in limitation of thermodynamics, the magnetization is not zero at high temperature.

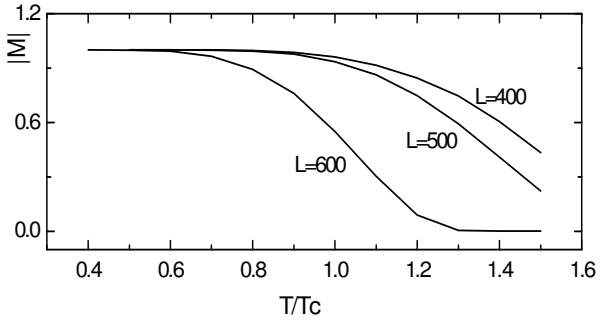


Fig.2 The Dependence Relationship between the Magnetization and the Size of Dot-square line. Data is about two Dimentions Ising Model.

On Infinite Lower Order of Vector Valued Dirichlet Series

Wanchun Lu

Department of Mathematics, Pingxiang University, Pingxiang ,337055, China

luwanchun540@163.com

Keywords: vector valued Dirichlet series, analysis functions, infinite order, growth.

Abstract: In this paper, the infinite lower order of vector valued Dirichlet series is investigated. By using a kind of new growth parameters of infinite lower order of analysis functions is introduced, the characterizations of coefficients of series are obtained.

Introduction

Let

$$f(s)=\sum_{n=0}^{+\infty}a_n e^{-\lambda_n s}\ , s=\sigma+it\ , (\sigma,t\ \text{ are real variables}), \tag{1}$$

where $a_n's$ belong to a complex commutative Banach algebra B with identity element ω with $\|\omega\|=1$ and $\lambda_n's\in\mathbb{R}$ satisfy the conditions $0=\lambda_0<\lambda_1<\lambda_2<\cdots<\lambda_n\uparrow+\infty$

$$\overline{\lim_{n\to+\infty}}\frac{\log\|a_n\|}{\lambda_n}=0\ ,\ \overline{\lim_{n\to+\infty}}\frac{n}{\lambda_n}=D<+\infty\ , \tag{2}$$

Then, the vector valued Dirichlet series in (1) represents an analytic function $f(s)$ in right plane(see [1]). In [1], B. L. Srivastava defined the growth parameters such as order, type, lower order, lower type of the vector valued analytic Dirichlet series. He also obtained the result for coefficient characterization of order and type. G.S. Srivastava [2] studied generalized order and generalized type of slow vector valued Dirichlet series. And he [3] studied relative type of this series also. In this paper we obtain infinite lower order of vector valued Dirichlet series.

For the vector valued analytic function $f(s)$ defined as above by (1) the maximum modulus, the maximum term and the index of maximum term are defined as

$$M(\sigma,f)=\sup_{-\infty<t<+\infty}\{\|f(\sigma+it)\|\}\ (\sigma>0)\ ,$$

$$m(\sigma,f)=\max_{n\in N}\{\|a_n\|e^{-\lambda_n\sigma}\}\ (\sigma>0)\ ;$$

$$N(\sigma)=\max_{n\in\mathbb{N}}\{n:m(\sigma,f)=\|a_n\|e^{-\lambda_n\sigma}\}\quad(\sigma>0)\ .$$

The order ρ and the lower order λ of $f(s)$ are defined as

$$\rho=\overline{\lim_{\sigma\to0}}\frac{\log^+\log^+M(\sigma,f)}{-\log\sigma}\ ,\quad\lambda=\underline{\lim_{\sigma\to0}}\frac{\log^+\log^+M(\sigma,f)}{-\log\sigma}\ .$$

We shall call the vector valued analytic function $f(s)$ to be of infinite order growth if $\rho=\infty$.

Let Δ_0 be the class of all functions β satisfying the following two conditions:

(i) $\beta(x)$ is defined on $[a,\infty)$, $a>0$, and is positive, strictly increasing, differentiable and tends to ∞ as $x\to\infty$;

(ii) $\dfrac{\mathrm{d}\beta(x)}{\mathrm{d}\log x}=o(1)$ as $x\to\infty$.

For a vector valued analytic function $f(s)$ given by (1) and $\beta(x)\in\Delta_0$, set

$$\lambda(\beta, f) = \varliminf_{\sigma \to 0} \frac{\beta(\log^+ M(\sigma, f))}{-\log \sigma}.$$

Then $\lambda(\beta, f)$ will be called, respectively, lower β-order of $f(s)$. To avoid some trivial cases we shall assume throughout that $M(\sigma, f) \to \infty$ as $\sigma \to 0$.

Main Results

Lemma 1

If the vector valued Dirichlet series given by (1) satisfies (2), then

$$m(\sigma, f) \le M(\sigma, f) \le K(\varepsilon) m(\sigma(1-\varepsilon), f) \frac{1}{\sigma},$$

where $K(\varepsilon)$ is a positive number of ε and $f(s)$.

Proof: From the second equation of (2), for given $\varepsilon > 0$, there exists an $n_0 = n_0(\varepsilon)$, such that for $n > n_0$, $n < (D+\varepsilon)\lambda_n$. Taken $\sigma > 0$, $\varepsilon \in (0, \sigma)$, we have

$$\begin{aligned} M(\sigma, f) &\le \sum_{n=1}^{n_0} \|a_n\| e^{-\lambda_n \sigma} + \sum_{n=n_0}^{\infty} \|a_n\| e^{-\lambda_n (1-\varepsilon)\sigma} e^{-\lambda_n \varepsilon \sigma} \\ &\le n_0 m(\sigma, f) + m((1-\varepsilon)\sigma, f) \sum_{n=n_0+1}^{\infty} e^{-n\varepsilon\sigma/(D+\varepsilon)} \\ &< n_0 m(\sigma, f) + \frac{m((1-\varepsilon)\sigma, f)}{1 - e^{-\varepsilon\sigma/(D+\varepsilon)}} \end{aligned} \tag{3}$$

The lemma now follows from (3) and the well known relation $m(\sigma, f) \le M(\sigma, f)$.

Lemma 2

If the vector valued Dirichlet series given by (1) satisfies (2), then

$$\lambda = \varliminf_{\sigma \to 0} \frac{\beta(\log^+ m(\sigma, f))}{-\log \sigma}.$$

Proof: By the first inequality of Lemma 2.1, this gives, since $\beta \in \Delta_0$, that

$$\varliminf_{\sigma \to 0+} \frac{\beta(\log^+ m(\sigma, f))}{-\log \sigma} \le \varliminf_{\sigma \to 0+} \frac{\beta(\log^+ M(\sigma, f))}{-\log \sigma}. \tag{4}$$

By the second inequality of Lemma 2.1, we have

$$\begin{aligned} \log^+ M(\sigma, f) &\le \log^+ m(\sigma(1-\varepsilon), f) - \log \sigma + O(1) \\ &\le C \log^+ m(\sigma(1-\varepsilon), f) \cdot (-\log \sigma) \end{aligned} \tag{5}$$

for all $\sigma (\sigma > 0)$ sufficiently close to 0. Here C is a constant. Now, (5) gives

$$\beta(\log^+ M(\sigma, f)) \le \beta(\log^+ m(\sigma(1-\varepsilon), f)) + \log((-\log \sigma)^C) \cdot \left. \frac{\mathrm{d}\beta(x)}{\mathrm{d} \log x} \right|_{x = x^*(\sigma)},$$

where $\log^+ m(\sigma(1-\varepsilon), f) < x^*(\sigma) < C \log^+ m(\sigma(1-\varepsilon), f)(-\log \sigma)$. This easily gives

$$\varliminf_{\sigma \to 0+} \frac{\beta(\log^+ M(\sigma, f))}{-\log \sigma} \le \varliminf_{\sigma \to 0+} \frac{\beta(\log^+ m(\sigma, f))}{-\log \sigma} \tag{6}$$

Theorem 1

If the vector valued Dirichlet series given by (1) satisfies (2) and is lower order $\lambda(\beta, F)$, then

$$\lambda(\beta,f)\geq\varliminf_{k\to\infty}\frac{\beta(\lambda_{n_{k-1}})}{\log\lambda_{n_k}-\log^+\log\|a_{n_k}\|}$$

for any increasing sequence $\{n_k\}$ of natural numbers.

Proof: Let $\theta=\varliminf_{k\to\infty}\frac{\beta(\lambda_{n_{k-1}})}{\log\lambda_{n_k}-\log^+\log\|a_{n_k}\|}$. First, let $0<\theta<\infty$. Then given $\varepsilon>0(\varepsilon<\theta)$, there exist $k_0=k_0(\varepsilon)$ such that for all $k>k_0$, we have

$$\log\|a_{n_k}\|>\lambda_{n_k}\exp\{-\frac{\beta(\lambda_{n_{k-1}})}{\theta-\varepsilon}\}.$$

Choose $\sigma_k=\frac{1}{2}\exp\{-\frac{\beta(\lambda_{n_{k-1}})}{\theta-\varepsilon}\}$, $k=k_0+1,k_0+2,\cdots$. Let $\sigma_{k+1}\leq\sigma\leq\sigma_k$, then, by Lemma 2.1, the above inequality gives

$$\begin{aligned}\log^+M(\sigma,f)&\geq\log\|a_{n_k}\|-\sigma\lambda_{n_k}\geq\log\|a_{n_k}\|-\sigma_k\lambda_{n_k}\\&\geq\lambda_{n_k}\exp\{-\frac{\beta(\lambda_{n_{k-1}})}{\theta-\varepsilon}\}-\sigma_k\lambda_{n_k}\geq\sigma\beta^{-1}(-(\theta-\varepsilon)\log(2\sigma)).\end{aligned}$$

So

$$\beta(\frac{1}{\sigma}\log^+M(\sigma,f))\geq(\theta-\varepsilon)\log(\frac{1}{2\sigma}),$$

or

$$\beta(\log^+M(\sigma,f))+\log(\frac{1}{\sigma})\cdot\frac{\mathrm{d}\beta(x)}{\mathrm{d}\log x}\bigg|x=x^*(\sigma)>(\theta-\varepsilon)\log(\frac{1}{2\sigma}),$$

where $\log M(\sigma,f)<x^*(\sigma)<\frac{1}{\sigma}\log M(\sigma,f)$. This easily gives, since $\beta\in\Delta_0$, that

$$\lambda(\beta,f)\geq\theta. \tag{7}$$

(7) is obvious for $\theta=0$. For $\theta=\infty$, the above arguments with an arbitrarily large number in place of $\theta-\varepsilon$ give $\lambda(\beta,f)=\infty$. This proved the lemma.

Theorem 2

If the vector valued Dirichlet series given by (1) satisfies (2) and β-order $\rho(\beta,F)$ of $f(s)$ is non-zero. Further, let $\varphi(n)=\frac{\log\|a_n\|-\log\|a_{n+1}\|}{\lambda_{n+1}-\lambda_n}$ be a non-decreasing function of n for $n>n_0$. Then

$$\lambda(\beta,f)=\varliminf_{n\to\infty}\frac{\beta(\lambda_{n-1})}{\log\lambda_n-\log^+\log\|a_n\|}.$$

Proof: As $\varphi(n)$ forms a non-decreasing function for $n>n_0$, it follows that $\varphi(n)>\varphi(n-1)$ for infinitely many values of n, since otherwise $\rho(\beta,f)=0$. Clearly $\varphi(n)\uparrow 0$ as $n\to\infty$. When $\varphi(n)>\varphi(n-1)$, the term $\|a_n\|\mathrm{e}^{-\lambda_n\sigma}$ becomes the maximum term and we have

$$m(\sigma,f)=\|a_n\|\mathrm{e}^{-\lambda_n\sigma}\quad\text{for}\quad\varphi(n)>-\sigma\geq\varphi(n-1).$$

By Lemma 2.2, we have

$$\lambda(\beta,f)=\varliminf_{\sigma\to0}\frac{\beta(\log^+m(\sigma,f))}{-\log\sigma}.$$

First, suppose that $0<\lambda(\beta,f)<\infty$, then given $\varepsilon>0$, there exists $\sigma_1=\sigma_1(\varepsilon)>0$ such that for $0<\sigma<\sigma_1$, we have

$$\beta(\log^+ m(\sigma,f))\geq\overline{\lambda}\log\frac{1}{\sigma},$$

where $\overline{\lambda}=\lambda(\beta,f)-\varepsilon$. Let $\|a_{n_1}\|e^{-\lambda_{n_1}\sigma}$ and $\|a_{n_2}\|e^{-\lambda_{n_2}\sigma}$ ($n_1>n_{0,}\varphi(n_1-1)>-\sigma_1$) be two consecutive maximum terms so that $n_1\leq n_2-1$. Let $n_1\leq n\leq n_2-1$. It is easily seen that $\varphi(n_1)=\varphi(n_1+1)=\cdots=\varphi(n)=\cdots=\varphi(n_2-1)$ and that

$$\|a_n\|e^{-\lambda_n\sigma}=\|a_{n_2}\|e^{-\lambda_{n_2}\sigma}\quad\text{for}\quad-\sigma=\varphi(n).$$

Hence,

$$\beta(\log\|a_n\|+\lambda_n\varphi(n))\geq\overline{\lambda}\log(-\frac{1}{\varphi(n)}). \tag{8}$$

By the first equation of (2) and $\varphi(n)\uparrow 0$ as $n\to\infty$, and notice that $\varphi(n)$ is non-decreasing, (8) gives

$$\beta(\lambda_n)\geq\overline{\lambda}\log(-\frac{1}{\varphi(n)}) \tag{9}$$

for all sufficiently large values of n.

Again, as $\varphi(n)$ forms a non-decreasing function of n for $n>n_0$, we have

$$\log\|a_{n+1}\|=\log\|a_{n_0}\|+\sum_{j=n_0}^{n}(\lambda_j-\lambda_{j+1})\varphi(j)\geq\log\|a_{n_0}\|+(\lambda_{n_0}-\lambda_{n+1})\varphi(n).$$

Therefore

$$\log^+\log\|a_{n+1}\|\geq\log^+(\log\|a_{n_0}\|+\lambda_{n_0}\varphi(n))+\log^+(-\lambda_{n+1}\varphi(n))+o(1),$$

or

$$\frac{\log\lambda_{n+1}-\log^+\log\|a_{n+1}\|}{\beta(\lambda_n)}\leq-\frac{\log^+(-\varphi(n))}{\beta(\lambda_n)}+o(1).$$

Using (9), we have

$$\lambda(\beta,f)\leq\varlimsup_{k\to\infty}\frac{\beta(\lambda_{n-1})}{\log\lambda_n-\log^+\log\|a_n\|}. \tag{10}$$

The above inequality is obvious for $\lambda(\beta,f)=0$. When $\lambda(\beta,f)=\infty$, the above arguments with an arbitrarily large number in place of $\overline{\lambda}$ give that

$$\varlimsup_{n\to\infty}\frac{\beta(\lambda_{n-1})}{\log\lambda_n-\log^+\log\|a_n\|}=\infty.$$

Finally, by Theorem 2.1 and (10) we can prove the theorem.

An Improved Mean Filter Algorithm for Impulse Noise Elimination

Tang Wang[1, a],Tang Jin[1, b]

[1]School of Automation, Beijing University of Posts and Telecommunications, Beijing, China

[a]tangwang@bupt.edu.cn, [b]tangjin@bupt.edu.cn

Keywords: Standard Mean Filter, Threshold, Impulse Wave, Noise Detection

Abstract: Since the standard mean filter has some drawbacks, an improved mean filter is proposed in this paper to overcome them. In this improved algorithm, noise detection is used to find the noise which is caused by impulse wave in the image. Based on the result of noise detection, window size would be selected in the improved mean filter to minimize the influence of the noise. According to the result of computer simulation, it shows that the improved mean filter is much more efficient than the standard mean filter in eliminating the impulse noise as well as in protecting the details of the image. It also shows its advantage in filtering speed.

Introduction

When images are formed or delivered or processed, they are easily to be influenced by impulse noise, which would cause the loss of information on image details and result in blurred images [1]. So in order to minimize the impact of the impulse noise, many filtering methods are used to solve these problems. The standard mean filter is widely used in this kind of situation, for its simplicity and good results. It replaced each point with the average value of the points around. However the standard mean filter still has its own drawbacks: when the detect window is small, it can preserve the details of the image, but cannot remove the noise effectively; when selecting a big detect window, it can remove the noise more effectively, but would damage the details of the image while eliminating the impact of impulse noise, and make the image blurred [2]. In this case, an improved mean filter is proposed to solve the problem. It has two steps to fulfill its task: First, it detects the noise points and separates them with the image points; Second, it uses the standard mean filter to deal with those noise points and keep the image points unchanged. So, the improved mean filter would wipe out most influence caused by the noise and protect the details of the image at the same time.

The Improved Mean Filter

The improved mean filter has two steps: detect noise points and minimize the influence of those noise points.

Detect Noise Points

Detect noise points is an important step, it is the foundation of the improved algorithm. There are many ways to detect noise points. In reference [3], it finds out the maximum point and the minimum point of the image, and uses them to divide the image into several blocks. Then it regards the medium value of maximum point and minimum point as a threshold, and uses it to judge whether a point is image point or noise point [3]. But the method of detecting noise point in this paper is different. Since the most image points are far away from 0 or 255, but the most impulse noise points are gathered near 0 or 255[4]. So the noise points have a great chance to be the minimum points or the maximum ones of the image. Take a uncheck point P(i,j) for example, the value of this point is assumed to be V(i,j), the aggregate of the point and the other eight points around it is supposed to be:

$$A_{i,j} = \{v(i+a,j+b) \mid a,b \in [-1,1] \text{ and } a,b \in N\} \quad (1)$$

The maximum value and minimum value of Ai,j is remarked as Max(i,j) and Min(i,j). If V(i,j) happens to equal to either Max(i,j) or Min(i,j), then it would be treated as a suspicious point. If it is a medium point, then it would be treated as an image point and kept unchanged. The suspicious point could be either noise point or image point, so it is necessary to judge it one more time. The rest values of Ai,j, which are equal to neither Max(i,j) nor Min(i,j), are formed as another aggregate Ri,j. But, if the rest values are equal to either Max(i,j) or Min(i,j), then, they all would be in the aggregate Ri,j. Once the aggregate Ri,j is fixed, according to the number of the values in Ri,j, the mean value of Ri,j is known, and it is named M(i,j). If the difference between V(i,j) and M(i,j) is below the threshold T, then the point P(i,j) would be treated as a image point. Otherwise, the point P(i,j) would be treated as a noise point.

So, to judge whether a point is a noise point, it has two conditions to meet:

- V(i,j) = Max(i,j) or V(i,j)= Min(i,j)
- | V(i,j) - M(i,j) |> T.

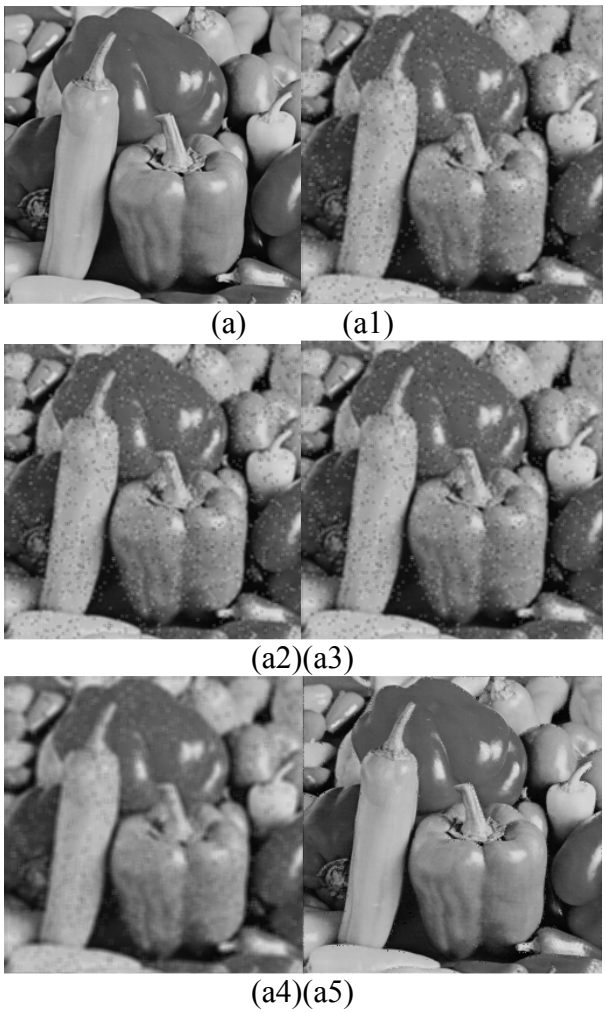
Filter the Image

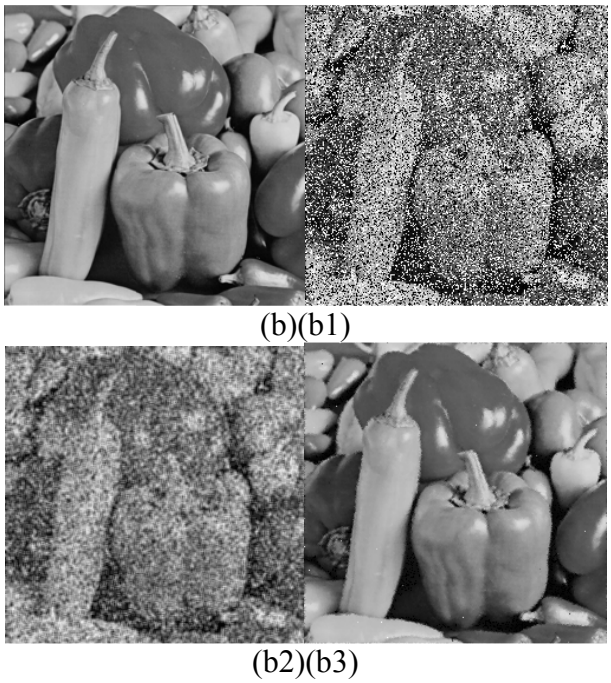
Once those noise points are set, the next step is to filter the image. Take a 3*3 window for example, when the point P(i,j) is regarded as a noise point, the filter method is to replace the point value V(i,j) with M(i,j), the mean value of the aggregate Ri,j **.**

Experiments and Analysis

In order to verify this theory, several experiments were taken to show the effect of this theory. The results of the experiments are displayed as follows.

In figure1, image(a) is the original image without any noise, image(a1) is the noise image with4% impulse noise points. Image(a2) and image(a4) wereboth filtered by standard mean filter.Image(a2)was filtered by a 3*3 filter window, but image(a4) was filtered by a 5*5 filter window. It can be seen that image(a2) still has some noise points left, but the details of the image are kept well. In image(a4), there are less noise points, but the image become a little fuzzy. Things are better in image(a3) and image(a5), which were filtered by the improved mean filter. Image(a3) was filtered by a 3*3 filter window and image(a5) was filtered by a 5*5 filter window. The image(a3) and image(a5) are more clear compared with image(a2) and image(a4), and have less noise points than image(a2) and image(a4).





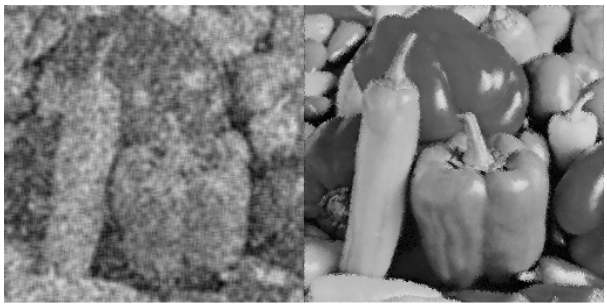


Fig. 1. Experiment images with 4% impulse noise: (a) original image;(a1) 4% impulse noise image;(a2) the 3*3 standard mean filter result;(a3) the 3*3 improved mean filter result; (a4) the 5*5 standard mean filter result; (a5) the 5*5 improved mean filter result

(b4) (b5)

Fig. 2. Experiment images with 40% impulse noise: (b) original image;(b1) 40% impulse noise image;(b2) the 3*3 standard mean filter result;(b3) the 3*3 improved mean filter result; (b4) the 5*5 standard mean filter result; (b5) the 5*5 improved mean filter result

To analyze the algorithm result in a quantitative way, signal to noise ratio (SNR) is chosen to be a standard in this paper. The function of SNR is:

$$\text{SNR}= 10\lg\left[\frac{\sum_{i,j} F_{i,j}^2}{\sum_{i,j}\left(F_{i,j}-V_{i,j}\right)^2}\right]. \quad (2)$$

In this function, V(i,j) is supposed to be the original point value of the point P(i,j), F(i,j) is supposed to be the final point value of P(i,j) after the filter part. The parameter i should be in the range of 0 – w, w is the width of the image, and the parameter j should be in the range of 0 – h, h is height of this image.

Judging from table 1, when the density of impulse noise is low, the improved mean filter has improved about 50% than the standard mean filter in signal to noise ratio, which means it does a better job than the standard mean filter. When impulse noise points are almost as many as image points, the improved mean filter has obvious superiority. It has almost twice the success rate than the standard mean filter, which may directly tell from image (b3) and image(b5). They are much clear than image (b2) and image (b4). According to table 1, it also indicates that improved mean filter has a better effect when uses a small filter window than a big one.

TABLE 1.SNR VALUES FOR EACH IMAGE

Noise / SNR / Method	4%	40%
Standard mean filter 3*3 window	20.6739	10.7870
Improved mean filter 3*3 window	32.4051	25.4450
Standard mean filter 5*5 window	19.5391	12.2100
Improved mean filter 5*5 window	28.6549	21.0664

Compared with those two mean filter, the advantage of the improved mean filter is obvious. It also shows that it is necessary to divide noise points from image ones, and to filter the noise points instead of the whole image.

Conclusion

Based on the standard method of mean filter, an improved method is proposed in this thesis to eliminate the impact of impulse noise. According to the property of impulse noise, and the

difference between impulse noise points and image points, two steps are taken to find noise points. First, find the suspicious points as much as possible, avoiding omissions. Second, use another function to ascertain the noise points among them. This method has solved the difficulty between minimizing the impact of those noise points and protecting the details of the image to a large extent.

Keywords: Fast Independent Component Analysis (FastICA), dynamic background extraction

Abstract: To solve dynamic background extraction in complicated outdoor surveillance, a method of background extraction based on fast independent component analysis(FastICA) is presented. Since foreground regions and background in an image are considered to be independent, and background images in video show a high correlation coefficient, the method can directly recover the background signal without recover other source signals. In this paper, the principle of FastICA are introduced, and the detailed processes of the method and results are given, which show that the method can realize extracting background image .

Introduction

In recent years, Researchers at home and abroad has done a lot of research on the algorithm for background extraction, Summed up in two categories：The first category is traditionally built on the multi-frame method which is based on the statistical, statistical histogram method, statistical value method, The methods above are more suitable for the background of simple situation, It can get the better effect of the background image. The second category is as processor computing power increased, some more complex algorithm of background extraction, such as block method, selective updating method ,Single Gauss model method, Gaussian mixture distribution model method[1]. Block method is the research and analysis of adjacent pixels, more effective information can be used, reduce the calculation of s redundancy brought by background model of pixels forms and improve the speed of the system. Single Gauss model, Gauss mixture distribution model can correctly initialize model which in the scene contains no moving objects, there are some difficulties in practical application. Independent component analysis has find a linear transformation for non Gauss data, making signals between components are statistically independent or as independent as possible, if the image of the foreground and background images that are independent of each other ,It should use the independent component analysis method to extract background.

Independent Component Analysis is a method to extract independent source signals from mixed signals, It is a novel blind source separation technology to realize the enhancement and analysis of signal, which making the multi-channel signal accord to the principle of statistical independence and using the optimization algorithm to decompose the signal into several independent components[2,3], ICA is a statistical analysis method based on higher-order statistics characteristic of signal, Currently in speech recognition, communications, biomedical signal processing and other fields, It has been widely used. In image processing, mainly used in image denoising, face recognition, feature extraction of medical image[4,5], But the ICA used in study on background extraction is relatively less, is a relatively new field of study.

Background extraction

The modern monitoring technology is committed to establishing the mapping relation between image and the description of the event, making the computer filter out the useless or interference information from the video data which is massive dynamic, uncertain , automatic analysis, extracting the crucial and useful information from video source, and convert into knowledge and decision.

When the monitoring scene in a fixed light, fixed background environment, each background pixel enough to cope with the impact of image noise by modeling with Single Gauss model method; In light change with the time, adaptive single Gauss model can correctly model the background; however, when there are dynamic objects in the background scene, the single Gauss model is incapable to take action.

For the two kinds of model of dynamic background used most often is mixed Gauss model and non parametric model. Gauss mixture model and non parameter model can well model the dynamic scene, but the consumption of computation and memory is large, It is difficult to detect the moving targets on real-time.

In addition, when the background image which obtained by the above method having a motion detection by background subtraction method , also need to continuously update the background in order to adapt to the change of scene, and when updated needed to follow the FIFO rule, the earliest sample will be abandon when the latest sample is added in the model . But if the foreground image and background image in the image are recognized as two independent source, using independent component analysis method to realize background subtraction without updating the background[6]。

FastICA algorithm

The model based on ICA as shown in Figure 1. Assuming there are M unknown. The independent signals is:

$$s(t) = [s_1(t), s_2(t), s_3(t), \cdots s_m(t)]^T$$

The observation signal received which linear stacking on N sensors through the detection and analysis system of unknow. The signal is

$$x(t) = [x_1(t), x_2(t), x_3(t), \cdots x_n(t)]^T,$$

and X=AS,A is called hybrid systems (or matrix).

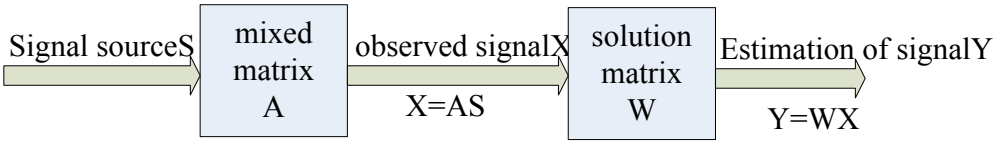

Fig. 1 The basic ICA model

W in Fig. 2 is a solution of mixed system (or matrix), Observations signals X get through the system and then obtained the output signal Y(t) which is close to S(t). This process can be expressed by Y(t)=WX(t). the basic idea of the ICA algorithm is to solve the separation system W, enable the output signal Y(t) statistical independence as possible, to approaching of the independence source signal S(t).

FastICA algorithm, or the fixed point algorithm, is that Hyvärinen and others are the first to propose and develop in 1997[7], FastICA algorithm according to the objective function can be divided into three algorithm: based on kurtosis, based on maximum likelihood, based on maximum entropy, The more commonly used is the FastICA algorithm based on the maximum entropy. Treat negative entropy maximum as each iteration of the data direction, Achieved that extracting the independent component in order, Fully reflects the projected track that is the traditional idea of linear transformations. In addition, the algorithm based on the maximizing principles of non-Gaussian, use the optimization algorithms of the fixed point, making the convergence more quickly and healthy.

When use the FastICA algorithm based on negative entropy maximum as a search direction, For the random variable Y whose probability density is P(y), The negative entropy is defined as:

$$J(y) = H(y_{gauss}) - H(y)$$

In the formula y_{gauss} is a Gaussian random variable and the random variables y have the same mean and covariance matrix.

$$H(y) = -\int P_y(\xi) \lg P_y(\xi) d\xi$$

It is the differential entropy of the random variable Y. When calculating in practical, Using the approximate calculation

$$J(y) \propto [E\{G(y_{gauss})\} - E\{G(y)\}]^2$$

Its extreme value of negative entropy corresponds to the extreme of G(y), After creating the negative entropy maximum goal function, To seek the extreme value based on Newton iteration method, get the independent component.

Background extraction in image sequences based on FastICA algorithm

Compared with the average of FastICA algorithm, the processing of independent component of the image has increased to three steps: the first is to put an image into a one-dimensional vector; the second is to handle with the independent components of the decomposition, the third is to use the reverse operation to process independent component which is processed, and then get the processed images.

The specific steps that the achivement of the background extraction method based on surveillance video image sequences are as follows:

1) Regard every frame of two-dimensional image sequence signals as a input observation source signal X;

2) Mean value for X, enable $E\{x_i\} = U$.

3) Albinism process for X, making the signal that albinism processed Z satisfied with $E\{zz^T\} = I$.

Albinism process: asking for the autocorrelation matrix transformation of the matrix of observational data source, asking for characteristic values, sort it and leaves the characteristic value which corresponds to the signal vector.

4) Initialize the random weight-vectorW_i of Z_i, Setting convergence errors $0 < \varepsilon << 1$;

5) Calculations $W_i(k)$ and $W_i(k+1)$ based on Newton iteration method, k is the number of iterations, until the D-value between $W_i(k)$ and $W_i(k+1)$ is less than the convergence error ε.

6) After extracting a component, remove the independent components from the observed signal, calculate the next separate component;

7) When a loop exceeds a preset value, stop the search.

8) To restore the Y_i to a two-dimensional image.

The experiment and analysis

The experimental data, the two section monitoring video are from the Front Gate of one scenic spot of Beijing, the frame rate of the video is 30fps, the size of image is 288 * 352, the environment of the Front Gate of attractions is complex, it is next to the parking lot, person flow is large, and there are many cars come and leave.。

Experiment first verify the text situation of the algorithm when there is only one individual object moving in a relatively simple environment, the experiment intercept 6 frames of images from the first videos, as shown in the Figure 2, a staff riding a bicycle crossing the road in the picture.

The detected background was shown in figure 3 (a), in order to show the effect, using the results to process the fourteenth images with background subtraction method, and the effect of binarizing as shown in figure(b).

(a)The 10th frame image (b)The 12th frame image (c)The 14th frame image

(d)The 16th frame image (e)The 16th frame image (f)The 20th frame image

(d)The 150th frame image (e)The 180th frame image (f)The 250th frame image

Fig. 4 The original image under complex environment

By the test, choosing more than 3 frames of image at random, using the algorithm of FastICA could effectively extract the background. Because of the environment of the testing video is simple, the experimental results are not enough to display the advantages of the extraction by the FastICA algorithm in dynamic background, so the text intercept 6 frames of images from second videos, as shown in figure 4 the video has a lot of visitors and in complex environment, a car driving into the middle of the parking lot, and pedestrians walking cross from the upper right of the image to the parking lot。

The 6th images of the complex environment processed by FastICA processing, test results are shown in figure 5. A lot of crossing pedestrians in the original video are weakened as the faint shadow, If they are simple thresholding can obtain a clear background, at the same time the detection results is effectively remove the coming car from a distance, and the pedestrian walk in the parking lot.。

Fig. 5 Background detection results

Conclusion

The experimental results show that using the independence of foreground image and background image and the correlation of the background image in video image sequences, regarding the background image and foreground image (or moving object) as two independent signal source, Fast independent component analysis method described in this article can be effective for extracting the background of outdoor surveillance video . Because of the complexity and diversity of the outdoor environment, more testing is needed for this method in the case of other mutation.

Keywords: network; frame relay; multi-protocol

Abstract. Local area network and wide area network are different network protocols, small and medium enterprises due to the geographical distribution of discrete and interface diversity, leading to its needs to be compatible with different network protocols, it is difficult to use a single network protocol to realize network architecture, and due to the ipv4 address scarcity, making its application or maintenance cost greatly increased, based on this, this paper presents the design of multi-protocol network architecture based on point-to-point protocol and frame relay, and with the advantages of the router is compatible with a variety of interfaces and protocols to connect different network interfaces, the paper also gives the configuration of routing information protocol and static routing through local area network, the paper presents the core information of frame relay and point-to-point protocol among the routers, and the paper gives the realization of the network address translation in the end.

Introduction

With the rapid development of network technology [1], making the network devices becomes more and more. The IP address is known as the Internet Protocol address. The common IP address is divided into IPv4 and IPv6; the small and medium-sized enterprises in the application of Internet addresses are the IPV4.

With the rapid expansion of the network scale, the IPv4 address has been turned into a kind of scarce resources, the local small enterprises and small companies are unable to afford the high IP address of the application and maintenance costs. To solve this problem, the relevant experts and proposes the NAT (Network Address Translation) solution [2-3].

RIP (Routing Information Protocol) is a distance vector routing protocol based on DVRP (Distance Vector Routing Protocol) interior gateway protocol IGP (Interior Gateway Protocol). The RIP protocol was first introduced by Xerox Company in the late development of the last century, at present RIP is the routing protocol UNIX operating system to the various types of routers and layer three switches and other equipment support [4-5].

RIP routing protocol uses the hops in the network to compute the distance to the destination network, the default maximum hop count is 15, and set network unreachable when the hop is 16, there are many factors that make RIP protocol suitable for LAN (Local Area Network) [6-8].

Frame relay is an open system interconnection OSI (Open System Interconnect) data link layer in the model, by using a simplified method to realize the exchange and transmission of data units in the data link layer, and to the gradual development of the X.25 packet switching technology, and supports the statistical multiplexing protocol, can be a single link above transmission a plurality of the virtual circuit VC (Virtual Circuit), effectively reduces the network cost and effective utilization of the link bandwidth of backbone network [2-3].

The advantages of router support different interfaces can connect different networks, compatible with PPP (Point-to-Point Protocol) and RIP protocol, the different regions of the different types of interfaces LAN eventually get through, through the configuration of different routing protocols, RIP and static routing for each segment can be connected to the each other, in order to achieve local through objective, then the private network of its service network to NAT mode into the public network.

In this paper, the architecture of the kind of Multi-Protocol Network design based on PPP and Frame Relay is proposed in section 2, and the configuration process of the architecture is proposed in section 3, and the whole paper is summarized in section 4.

The Design of the Kind Of Multi-Protocol Network Based on PPP and Frame Relay

The Composition of Multi-Protocol Network Design Based on PPP and Frame Relay

In this framework, as shown in Fig.1, the total of five routers, four of which are inside the local area network, and one is outside the network. There are four switches, three in the LAN, and one is outside the network.

The switch SW1's network is connected to the server, using the public address.

The network architecture, the switch SW1 and the router RT2 are outside the local area network, and the router RT2 is the egress router, between the RT2 and the RT5 connection through the PPP link, and uses PPP authentication.

RT5 is connected with the switch SW2, and connects the internet user.

RT2 and RT3 are connected by the frame relay connection, uses Frame Relay authentication, and the SW3 connects the common user network.

RT2 and RT4 are common connection; and the switch SW4 connects the common user network.

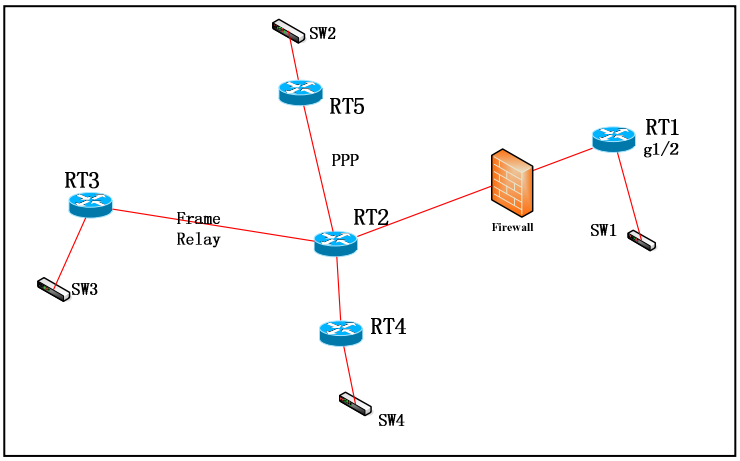

Figure 1. The Composition of the Multi-Protocol Network Based on PPP and Frame Relay

The Design of Multi-Protocol Routing

According to the planning, the network routing protocol is mainly used RIP and static route.

The RIP protocol through route poisoning routing information is used to guarantee the correctness and fault network directly connected routers.

Static routing is a routing protocol, its configuration is simple, and all the routers are required to configure a static route, so that it can reach all local area network. In the global network, all the routers and the switches should configure static routing table.

There are many routers have to open the RIP routing, such as RT2 and RT3, RT4, RT5 and other directly connected routers, all the other routers and switches need static routing.

The PPP Authentications

Specific certification process has the following three steps:

The first step: the main verification party sends a random number, and sends the main verification of the end users.The second step: the attested party receipts validation master validation request, check the local user password, if the configuration of the chap authentication password.The third step: the main verification party checks the information, and relies on MD5 algorithm to create an abstract for the message and the local password and authentication methods.

The Configuration Process of the Architecture

The Configuration of the Architecture

The configuration of the architecture comes as following: there are five routers and four switches in the architecture, as shown in Fig.2.

The router RT1 and the switch SW1 both locate outside the local area network and the router RT1 connect the switch SW1, and there is the virtual local network named vlan3 in the switch SW1, and the gateway is 100.1.3.1, and the net mask is 255.255.255.0.

The entire virtual local network is configured in the following picture.

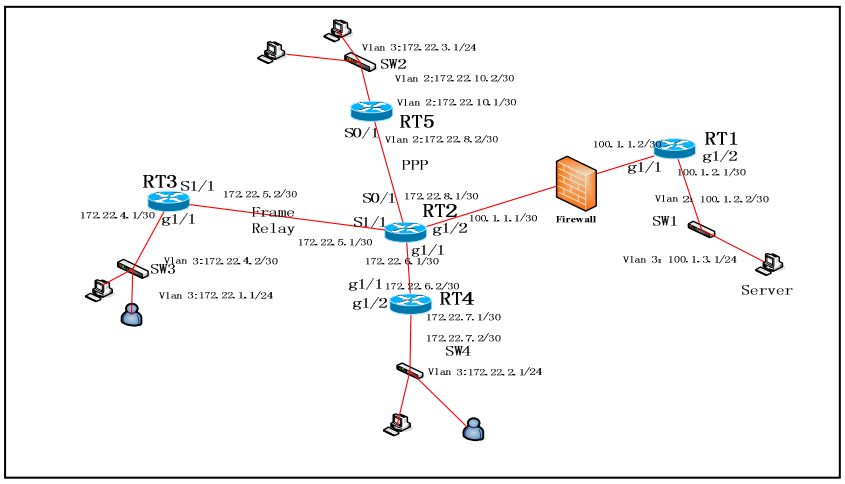

Figure 2. The Configuration of the Multi-Protocol Network Based on PPP and Frame Relay

The Configuration of the PPP Authentication

The PPP chap authentication set the RT2 as the server, and set RT5 as the client end, which is to be verified.

The system's interface on RTB, in the statement for the user and the key, and the password is set as the simple format

The configuration in the interface of the router RT2 comes as follows:

[RT2] local-user rt5
[RT2] password simple BBB
[RT2] service-type ppp
[RT2]Interface Serial0/1
[RT2- Serial0/1] Description link-to-rt5
[RT2- Serial0/1] Link-protocol PPP
[RT2- Serial0/1] PPP authentication-mode chap
[RT2- Serial0/1] PPP chap user RT5
[RT2- Serial0/1] PPP chap password simple BBB
[RT2- Serial0/1] IP address 172.22.8.1 255.255.255.252

The password must be the same in the router RT2 and in the router RT5.

The configuration in the interface of RT5 comes as follows:

[RT5] local-user rt2
[RT5] password simple BBB
[RT5] service-type ppp
[RT5] Interface Serial0/1
[RT5- Serial0/1] Description link-to-rt2
[RT5- Serial0/1] Link-protocol PPP
[RT5- Serial0/1] PPP authentication-mode chap
[RT5- Serial0/1] PPP chap user RT5
[RT5- Serial0/1] PPP chap password simple BBB
[RT5- Serial0/1] IP address 172.22.8.2 255.255.255.252

The Configuration of the Frame Relay

In order to configure the frame relay authentication, we need the corresponding port on the DCE (Data Communications Equipment) and DTE (Data Terminal Equipment) ends are respectively configured with an IP address.

The configuration in the router RT2 comes as follows:
[RT2] interface s1/1
[RT2-s1/1] description to RT3
[RT2-s1/1] link FR
[RT2-s1/1]FR interface-type DCE
[RT2-s1/1.0] interface s1/1.0 p2mp
[RT2-s1/1.0] FR DLCI 100
[RT2-s1/1.0] IP address 172.22.5.1 30
The configuration in the router RT3 comes as follows:
[RT3] interface s1/1
[RT3-s1/1] description to RT2
[RT3-s1/1] link FR
[RT3-s1/1] FR interface-type DTE
[RT3-s1/1.0] interface s1/1.0 p2mp
[RT3-s1/1.0] FR DLCI 100
[RT3-s1/1.0] IP address 172.22.5.2 30

The Configuration of the RIP

The router RT2 configures the RIP dynamic routing protocol comes as follows:
[RT2] rip 1
[RT2-rip1] version 2
[RT2-rip1] undo summary
[RT2-rip1] network 172.22.5.1
[RT2-rip1] network 172.22.6.1
[RT2-rip1] network 172.22.8.1
And the others routers are configured in the same way.

The Configuration of the Static Routing

All of the core equipments of RIP dynamic routing protocol configuration are completed, it's need to configure the default static routing.
The switch SW2 configures the static default route:
[SW2] ip route-static 0.0.0.0 0.0.0.0 172.22.10.1
The switch SW3 configures the static default route:
[SW3] ip route-static 0.0.0.0 0.0.0.0 172.22.4.1
The switch SW4 configures the static default route:
[SW4] ip route-static 0.0.0.0 0.0.0.0 172.22.7.1
The router RT5 configures the static default route:
[RT5] ip route-static 0.0.0.0 0.0.0.0 172.22.8.1
[RT5] ip route-static 172.22.3.1 24 172.22.10.2
The router RT2 configures the static default route:
[RT2] ip route-static 0.0.0.0 0.0.0.0 100.1.1.2
[RT2] ip route-static 172.22.10.1 30 172.22.8.2
[RT2] ip route-static 172.22.3.1 24 172.22.8.2
[RT2] ip route-static 172.22.4.1 30 172.22.5.2
[RT2] ip route-static 172.22.1.1 24 172.22.5.2
[RT2] ip route-static 172.22.7.1 30 172.22.6.2
[RT2] ip route-static 172.22.2.1 24 172.22.6.2

The Configuration of the NAT

The router RT2 uses the 100.1.4.1 to the 100.1.4.10 as the nat address-group, and the configures of the static default route in the router RT2 comes as follows:
[RT2] firewall enable
[RT2] nat address-group 1 100.1.4.1 100.1.4.10
[RT2] acl number 2001

[RT2-acl-basic-2001] rule 0 permit source 172.22.0.0 0.0.255.255
[RT2] interface GigabitEthernet1/2
[RT2- GigabitEthernet1/2] description link-to-rt1
[RT2-GigabitEthernet1/2] nat outbound 2000 address-group 1
[RT2-GigabitEthernet1/2] ip address 100.1.1.1 255.255.255.252

Conclusion

This paper discusses and summarizes the development of LAN point-to-point protocol, frame relay and RIP dynamic routing and static routing and other related areas, and sums up the characteristics of RIP and the configuration of the points, and gives the disposition of dynamic routing protocol RIP and frame relay implementation process, and finally completes the kind of multi-protocol network design based on point-to-point protocol and frame relay.

Keywords: Digital resources sharing, resources sharing, China, Southeast Asian, digital library.

Abstract. Resources development & sharing has become an important subject of widespread concern in the world and it is the inevitable demand of information society development. Sharing is not only a useful way to save money, reduce duplication of investment, improve resource utilization and realize resources complement, but also an important way to greatly improve the information flow and information services support capabilities, and promote society access to information in general. This paper introduces the importance of resources sharing between the libraries of China and Southeast Asian and it refers to the cooperation ways of digital resources sharing.

Introduction

As the core of building a digital library, the digital resources construction refers to the process in wich the information resources are selected, collected, organized and managed to form a usable digital resources system. The digital resource construction and sharing plays an important role in the implementation of the digital library extensive project.. With the development of China and southeast Asian free trade area, the cooperation is making big progresses between the countries. As a library based on social and economic service, we must sieze the opportunities to development in depth. Therefore, Digital resources sharing program becomes a current subject that is worth to be studied in depth.

Review of literature

Resource sharing has been the goal of libraries for many centuries. There is no one library that can afford to build a collection that is sufficiently comprehensive to satisfy all of its users' requests. By joining cooperative acquisition or collection development programs, libraries provide their users greater range of library materials or better depth of subject coverage [1].

Interlibrary loan (ILL)services facilitate the sharing of resources among libraries. As stated in ALA Interlibrary Loan code for the United States, “the purpose of interlibrary loan is to obtain, upon request of a library user, material not available in the user's local library” [2]. The increasing amount of electronic resources in libraries may have affected the use of ILL services. A study conducted by Egan [3] indicated that the requests for nonreturnable, photocopied materials decreased because there are more full-text e-journals available online now. Wiley and Chrzastowski found that the requests for periodical articles fell 26% between 1990 and 2003 because libraries started subscribing to more packaged periodical databases [4]. An investigation conducted by Beaubien (2007) [5] found that requests for nonreturnable materials decreased 4% while the requests for returnable materials (books, audio-visual materials, microfiches, etc.) increased 26% from 1998 to 2004. The statistical data on ILL in Taiwan from2001 to 2008 show similar trends. The number of requests for periodical article copies declined from168,620 items to 108,017 items, while the requests for monograph borrowing increased from 17,710 items to 38,322 items [6]. Walton (2008) [7] explained that the convenience of electronic resources did change the users' information behavior and that they prefer accessibility over

resource quality. Meanwhile, the growth of open access resources also reduces the number of requests for ILL.

The importance of Digital resources construction and sharing in libraries of China and Southeast Asian

The need to the free trade area development

The construction and development of China-Southeast Asian free trade area benefit the people in 11 countries of China-southeast Asian area. People in those countries are urgent to know the information about economy, society, civilization of those countries, so it offers a big chance to construct the digital resources system. It becomes an important project significantly. By construct the system, we could satisfy the need of people from these countries and improve the cross culture understanding and cooperation.

The need of library development

The world today has entered the time of globalization. In this time, library has been digitalizing, networking and media serving. Digital resource sharing project is a big advantage of library. So the digital resources sharing is the direction of library service in future.

The capacity of service improvement

Digital resources sharing and construction project could make the best of the resources and fund raising on one side, and on another side, it satisfies the need and want of readers and benefits the countries all involved into the work. So, the digitalizing resources construction project could improve the library service the best.

Resource Sharing is the key of library digital

Compared to other carriers in the form of resources, one of the biggest advantage of digital resources is the share ability. Under the principle of equality and mutual benefit between the Library and the libraries, even libraries and other relevant agencies to conduct resources sharing, complementary digital resources to expand the data sources, to improve the number of the library's digital resources. Special, enhance the overall competitiveness of the Library.

If the digital library are fragmented, the implementation of the principle not open shared, this will not only result in duplication of investment and low resource utilization of the phenomenon, the competitiveness of the digital library is a weakened.

Sharing of digital resources available from the following aspects:

Establish the concept of information resource sharing:

The digital technology allows a paper to this literature can easily become the electronic information, digital document delivery through the network a snap. However, some management concepts still remain only in the museum, can not think of the transfer of the Museum. Thus, even if the implementation of digital library information resources, information resources retrieval system is still closed, is still limited to the retrieval of the museum readers. In fact, the role of electronic library resources lies not only in terms of museum users, but also because the resources sharing. Thus, we must change management concepts, and establish the concept of resource sharing, and increase with the application in practice, so that in a networked environment to provide readers broader sources of information.

Increase efforts to share input into the construction

To establish a shared center, fully functional and running quickly shared network of information resources and reliable resources for the layout of the protection system is essential; other libraries to support each other, all library resources, special collection open to shared the harmonization and layout. Which need to invest greater human and material resources, digital resources shared building in the part of the library has some of the features, but in the current situation is far from enough, takes a great effort in the future for a long period of time need continuous attention is still the focus of digital library construction.

Formulate Sharing specification

Orderly operation of the shared resource good must Sharing of information resources, financial security, the rights and obligations of members, as well as information resources sharing system and operational mechanism, the overall layout to make clear. The introduction of punitive measures to destroy or hinder the behavior of Sharing and incentives contribute to the sharing of resources. Uniform operation of the standard specification starting point to develop a code of conduct, to create a favorable institutional environment for the library literature resources sharing.[8]

Cooperation ways to digital resources integration

Put the focus on the special digital documents

We could strengthen the communication among the libraries of China and Southeast Asian countries and integrate the digital resources of China and Southeast by the free trade area cooperation on culture. For example, the special documents. As we know, the cooperation focus mainly on economy. We could gather information related to economy cooperation of China and southeast Asian countries. By doing this, we could make a big progress on library service in the future.

Integrating the national digital documents with internet

With the development of the information, web, and other advanced technologies on information process, internet is a most important way to communicate. We could dive into a sea of knowledge with an easy searching engine. We could mal, a best of the internet to gather, chronicle, and download some knowledge and documents about Southeast Asian countries. One problem we will confront with is too many knowledge and resources. Sorting out the valuable information requires the wisdom and capacity of information collectors.

National digital document collection by official ways

First, cooperation on documents communication between government by visiting to Southeast Asian countries; Second, Actively contact with embassies and libraries to explore the future issues in details and practice that; Third, Siezing the opportunities of cooperation with free trace area and appeal the support of provincial governments and officials. Making best of document resources to gather, processing and indexing the related information for the further tmst and praise of official from other countries, then to sieze the opportunities to collect document resources of those countries.

Collecting the national digital documents resources from Southeast Asian countries by folk ways

With the trade cooperation with Southeast Asian countries, We will be happy to see more and more merchants entering the southeast Asian countries recently, and Southeast Asian merchants also look for opportunities on commercial development. Meanwhile, some big enterprises of China are standing on the southeast Asian countries, which bring more and more technicians and workers out of China. Library could sieze the good chance to employ the volunteers, merchants living in southeast Asian countries, workers, overseas and consultants to help collecting national digital resources.

Found the China and Southeast Asean digital document resources center

The center includes a platform of communication, information display platform and a library service website. Information resources sharing platform offers a media to exchange some selected document from neighbor provinces, and collect, process, and develop those information about southeast Asian countries. The main function of it is to collect information, check out and read, internet serve, information development and digital resources construction. Information service center divides into information searching reading rooms on a service platform. It becomes a largest scale information center in China. China and Southeast Asean library service web system mainly is an information base on construct, collect, intergrate, and develop the bilingual digital document resources system. After the establishment of the resource center, we will provide information checking service to southeast Asian countries with our human resource center and advanced internet technology, then we will build the close tie with southeast Asian libraries and copperate with Southeast Asian countries on document exchange, resource sharing and digital service.[9]

Conclusions

The benefits derives from resource sharing are increasing especially in this digital are. No one library in the world can have collection of everything and is not possible for a library to acquire every single item for its collection. With the advancement of latest technology, resource sharing is make easier to access any time, any where and by any one. Libraries must ensure that resource sharing must be carried out through cooperation and collaboration in order to fulfil the user needs and to stay relevant in this challenging era.

Construction and sharing of library digital resources in China and Southeast Asia is not only the need of library service but also the need of free trade development. Librarians in China and Southeast Asian countries should seize the opportunities to learn the significance of construction project, solve the problems and make the resource sharing project to be beneficial to economy and all people in China and Southeast Asian countries.

Keywords: Navigation Satellite System Simulation, Simulation Model Portability Standard, Model Framework, Simulation Reuse

Abstract: Performance Simulation for Global Navigation Satellite System (GNSS) that be used for performance simulation and evaluation analysis of the GNSS, is a part of the critical algorithm test and system index analysis for GNSS. In this article, the requirements of GNSS are analyzed firstly, and the characteristic of model portability for GNSS is studied, then the model integration framework based on Simulation Model Portability is proposed. The system architecture consists of model design, development, integrating, executing and analysis. Lastly, the regional performance of GALILEO Navigation Satellite System in China is tested and analyzed based on the integration framework.

Introduction

Global Navigation Satellite System (GNSS) are playing an increasingly important role in human life following communications and network. It can provide all-weather positioning, velocity-measuring and timing for the surface of the Earth and near-earth space users, and be widely used in both military and civil field[1]. GNSS consists of satellite subsystem, rocket system, operation control system, users subsystem, launching site subsystem and TT&C subsystem, is a space engineering system with very large scale and complex structure. To support system integration, functional verification, performance validation and analysis of GNSS, it is necessary to build model and simulate the behavior and processes of GNSS with modern computer simulation techniques and methods.

At present, there are been built or building four GNSS around the world, which are GPS,GLONASS, COMPASS and GALILEO. It attaches great importance to Simulation for GNSS in the course of construction. As simulation for GNSS depends on integrating multi-domain model and building complete circuit of navigation satellite system, it makes much more difficult for the scale and integrating. By the late nineties, the U.S. military began to large-scale simulation by using distributed interactive simulation technology for GPS. The Simulation Model Portability Standard[2,3] (SMP) was developed by European Space Agency in 2003, which were faced with difficulties by multi-domain model integration and analyzing during designing GALILEO, and supports integrating models for GALILEO and a series of aeronautical engineering.

The Define and Characteristic of Portability

Good portability of the navigation simulation model is critical to rapidly and effectively integration for the performance simulation of GNSS[4,5]. The High Level Architecture (HLA) method is used to solve the interoperability problem among heterogeneous simulation system. And if the performance simulation of GNSS which coupling between models is very complex will use HLA to integrate models, the performance and efficiency of the simulation, it will be significantly reduced, and the problem of types, computational complexity of GNSS analysis will not be solved, simulation in mass will not be realistic. And description of simulation model will be more normalization and standardization, which is a basic requirement for the development of model integration and reuse.

Simulation Model Portability Standard[6,7,8] (SMP) is developed for improving the portability, maintainability and reusability of modeling and simulation specification by European Space Agency (ESA) since 2003. SMP specification absorbs many advanced approaches in the field of software engineering and simulation, and extracted metadata information from the simulation model, and represented the model with Platform Independent Model (PIM) base on meta model, and developed simulator components, service components, model components and interfaces between them.

The separation of the simulation engine and model is one of basic method for simplifying the modeling work, easy reuse and integration model during modeling. Based on this, The SMP2 has introduced three design ideas:

1) Separation simulator component and simulation service component.

2) Separation Platform Independent Model (PIM) and Platform Specific Model (PSM).

3) Separation Design-Time Component (DTC) and Run-Time Component (RTC).

There are four forms in SMP2 simulation model components: PIM-DTC component , PIM-RTC component , PSM-DTC component and PSM-RTC component. SMP2 standard consists of SMP2 component model, meta model, C++ mapping mechanism and user's manual[8,12]. Model development and integration method based on SMP2 specification can be used for the research of the performance simulation system of GNSS.

GNSS's Model Integration Framework based Portability

The performance simulation of GNSS simulates and evaluates the performance of the GNSS's services segment, support to evaluate the performance indexes of global or regional grid[9,10,11]. For the different type of analysis task, the tasks can be further subdivided into many subtasks, and the development, integration and analysis of GNSS's model put forward higher requirements: Reusability of simulation model, Scalability of integration framework, Efficiency of the model development, Usability of system configuration.

According to characteristics of the above requirements and SMP2's specification, model framework, execution framework and integration framework of GNSS should be reasonably establish, will support many performance simulations and analyses[13]. Figure 1 shows the structure of the model components of GNSS, which includes every key model and core algorithm of different segments. In developing these models and algorithms, different organizations and users may not be used the same tools and implementation methods, but the interface of models and algorithms can be consistent with SMP2 specification, so that it make possible for reuse and transplantation of the model and algorithm .

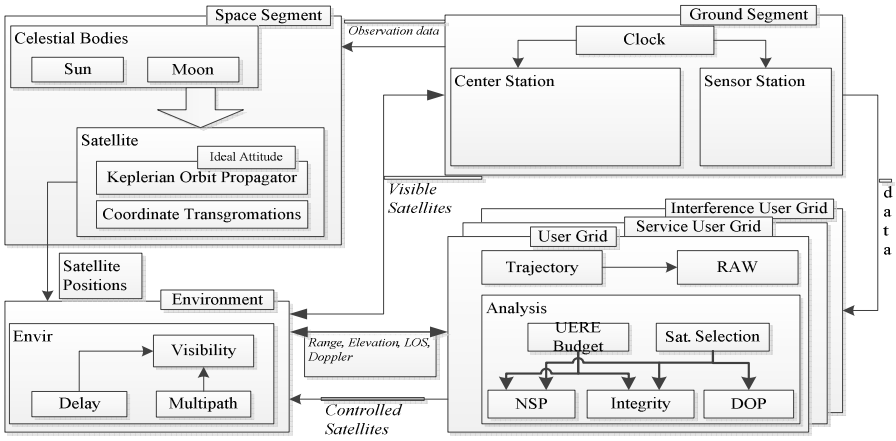

Fig. 1. The model components of GNSS simulation

Based on the navigation performance analysis, the model or algorithm required by different analyses is not the same, which requires the model framework has good reusability and integration. For example, during Visibility analysis, environmental segment model need to get positions of satellite and user in the current epoch, then calculate the observed elevation angle, in order to

determine the satellite's visibility; while analyzing Dilution of Precision (DOP), Navigation System Precision (NSP), user grid model need to obtain the visible satellites in the current epoch, then choose appropriate satellite selection algorithm, and calculate various types of DOP and NSP value by using the appropriate budget method of User Equivalent Range Error (UERE). In the above simulation, the basic models and algorithms is consistent and can be directly reused, while they also need to be quickly replaced for the validation and evaluation of key algorithms. So it is necessary to establish a unified simulation model integration framework to support reuse and integration of the various types of models and algorithms of navigation system. While Component-based and interface-based of SMP2 design method, a simplified portability navigation simulation model integration framework is showed in the fig. 2.

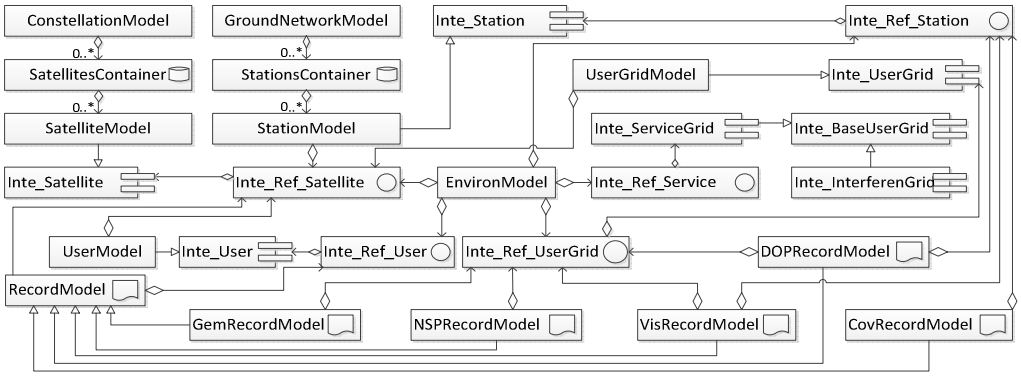

Fig. 2. Model integration framework based portability

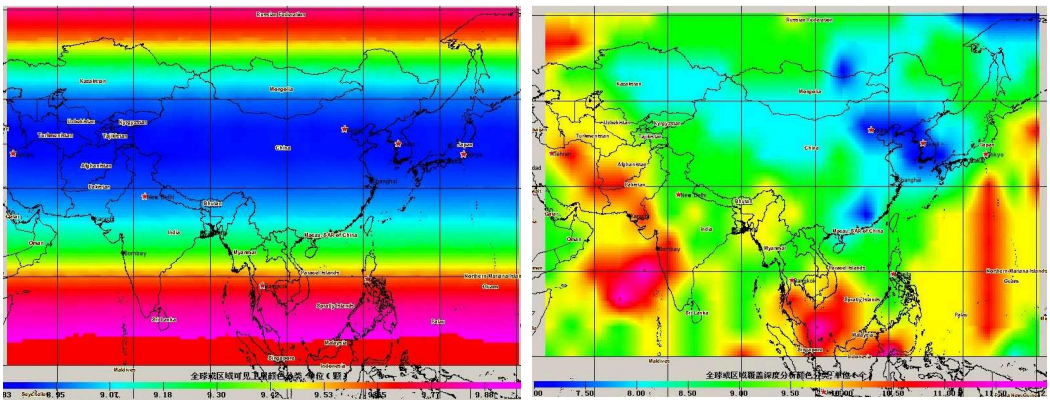
In the figure, SatelliteModel, StationModel represent the domain model of the satellite model, station model, which models design algorithm interface by SMP2 specification, such as Inte_Satellite, Inte_Station, etc. The other models can be referenced these models by accessing these interfaces, such as Inte_Satellite provide the satellite's health status, the orbital elements, etc. Some domain model users can use some model or algorithm to replace some model, for example the environmental model can select different delay correction algorithm for Ionospheric and Tropospheric for simulation, which include Egnos algorithm, Hopfield algorithm, Saastmanion algorithm, etc. SatellitesContainer, StationsContainer are various types of containers based on SMP2 specifications, and support the other model entities to query and manage these entities. Inte_Ref_Satellite, Inte_Ref_UserGrid provide references of the interface for domain models, these references may be multi-reference, such as EnvironModel is an environment model, and Inte_Ref_UserGrid is a one-to-many reference from EnvironModel to UserGridModel. RecorderModel, DOPRecorderModel are functional models, and indicate different recording models. Oriented performance simulation analysis, these recording models needs to provide the interface to logging simulation data, in order to analysis.

The method of separation application model framework and simulation scenario framework will help the domain user more focusing on the familiar navigation domain problems, rather than the specific implementation details of the model framework. The simulation users more focus on the development of the application platform or framework, not the details of the model or algorithm.

Experiment for GNSS Simulation Based Portability

According to above integrated model framework, the simulation application development and test architecture based on SMP2 for GNSS can be divided into simulation model design, development, integration and execution of four stages.

The main task of the model design phase of Navigation simulation is that designing SMP2 Catalogue file based on SMDL, model design documents. Simulation users can design model with class-based, interface-based, component-based, event-based and dataflow-based design approaches of SMP2, then can get the model's information, including object structure, combination structure and interaction structure.



The main task of the model development phase of navigation simulation is that translates models from Catalogue file into a model framework code, that is to say that transforms PIM into PSM, then designs a specific algorithm in the framework, finally a compiler is needed to generate binary models form sources.

The main task of the model integration phase of navigation simulation is that generates the Assembly file, which contains the configuration information and assembly relationships of the model instances, by using instance generation, configuring and integration of the model under the constraints of Catalogue based on SMDL.

The main task of the model execution phase of GNSS simulation is that generates the Schedule file, which arranges the scheduling strategy of navigation model's instance based on the Assembly file and SMDL.

By using above method, we study the performance simulation of GALILEO system. Based on the navigation performance indexes, we define 50°E~150°E, 0°N~60°N as an analysis region, 5°×5° as grid resolution, analyses include visibility, geometry, coverage, DOP, NSP, etc. Satellite orbit determination algorithm is Keplerian two-body orbital model, simulation cycle is a constellation regression cycle, simulation step is 300 seconds, and algorithm involved in the model are such as GPS, GALILEO algorithms.

Based on SMP2 method, we design and develop a software which support model development and simulation SMP2-based. The result of the test shows in Fig.3. Fig.3 (a) is a distribution diagram of the number of visible satellite in this region of GALILEO, there are most about from 8 to 9; Fig.4 (b) is a distribution diagram of number of ground stations in view at each time step in this region, most of the distribution about from 7 to 9. These results are consistent with the data provided by ESA.

(a) Regional Visibility (b) Regional Coverage

Fig. 3. Experiment results of GNSS simulation based on SMP2

Conclusions

In this paper, based on SMP2 specification, we study the model framework of GNSS simulation, and proposed an SMP2-based model integration framework for GNSS, then develop and integrate the models, to support the performance analysis of GNSS. Performance analysis by using traditional methods are tightly coupled with the specific needs of domain or expertise, when the constellation configuration is changed, or accuracy and approach of algorithm is changed, we need to re-develop, and the algorithms and models are lack of reusability and portability. Using the proposed method, domain staff will focus on the development of the domain model ,do not care about the simulation platform, so that the developed model can not only support the demonstration program, but can verify the performance impact caused by the different algorithms or models. Navigation simulation model based SMP2 specification are more reusability and portability.

Software engineering oriented SMP2 and integrating various behavior modeling formalisms around SMP2 is our next work.

A Fast Fault-identification Algorithm Tailored for Optical Interconnection Networks in high-performance computers

He Li*

College of Computer Science, Chongqing University of Posts and Telecommunications, Chongqing 400065, P.R.China

cquptheli@126.com

Keywords: optical interconnection; optical multi-mesh hypercube networks; diagnosability; pessimistic strategy; diagnosis algorithm

Abstract. Due to integrated positive features of both hypercube and tori, optical multi-mesh hypercube (OMMH) networks in high-performance computers are regarded as a class of promising optical inter- connection networks. This paper firstly derive that the diagnosability of OMMH under the pessimistic strategy is (2n+6)/(2n+6), which shows that the OMMH possesses strong self-diagnosingability. With the improved cycle decomposition method by Yang in *J. Parall. Distrib. Comput.* [10], a fast diagnosis algorithm to identify all faulty nodes *tailored for* OMMH, which runs in $O(N\log_2 N)$ time is also proposed, where N is the number of the processors of an OMMH.

Introduction

High-performance computers is based on high-performance processors, with hundreds of cores integrated onto a single die. Intra-chip and inter-chip communication networks are becoming critical components in such systems. Nanophotonics is a promising disruptive technology that can potentially achieve simultaneous improvements. Chip-level networks as opposed to cluster-level optical networks used in high-performance computing and data-centers have more challenges: the increasing size of multiprocessor systems makes the possibility that faulty processors present in such systems become large. *System-level diagnosis* [4] is an effective approach to identifying the faulty processors existing in the system and then isolating them or replacing them by fault-free processors. Among the different classes of diagnosis models to locate the faulty nodes, the PMC model [9] is possibly the most well studied one. This evaluation is reliable if and only if the testing processor is fault-free.

A scalable optical interconnection network called optical multi-mesh hypercube (OMMH) network[7, 8] which integrates positive features of both hypercube and mesh topologies is proposed. The OMMH network has been physically demonstrated using a combination of free-space and fiber optics technologies, and has shown good performance characteristics for a reasonable size network. Motivated by the graph decomposition techniques used in [5], this paper addresses the fault identification of OMMH under the PMC model. We will show that the (l,m, n)-OMMH is also (2n + 6)/(2n + 6)-diagnosable under the pessimistic diagnosis strategy. And then, a fast fault identification algorithm for optical multi-mesh hypercube networks using the PMC model is proposed,
which can run in $O(N\log_2 N)$ time, where N is the number of the processors of an OMMH.

This paper is organized as follows: In Section 2, we introduce the (l,m, n)-OMMH network and preliminaries. In Section 3, we prove the diagnosability of the (l,m, n)-OMMH under the pessimistic diagnosis strategy. A fast fault-identification algorithm for optical multi-mesh hypercube networks using the PMC model is proposed in Section 4. Finally, we give some concluding remarks in Section 5.

Preliminaries

A multicomputer system is modeled by the underlying graph G = (V (G),E(G)) of its interconnection network, with each node representing a processor and each edge representing a bidirectional communication link between two processors. More knowledge of graph theory, please reference[3] .

Definition 1 [7, 8]. *An* (l,m, n)*-OMMH network, denoted* $MH_n^{l\times m}$*, is defined as the Cartesian product graph* $T_{l\times m}\times Q_n$*, where* $T_{l\times m}$ *denotes an* $l\times m$ *Torus,* Q_n *denotes an* n*-cube.*

It is obvious from this definition that $l,m\geq 3$. Fig.1 present two small-sized OMMH networks with two methods.

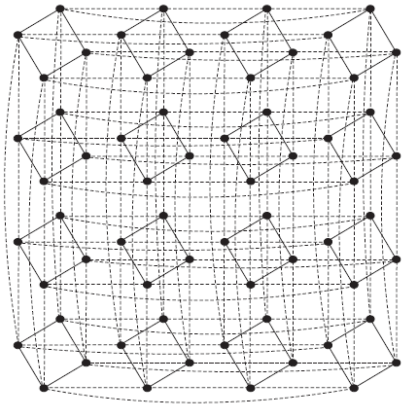

Fig.1 OMMH network $MH_2^{4\times 4}$

Remark 1. $MH_0^{l\times m} = T_{l\times m}$*, a torus with* l *rows and* m *columns.*

Theorem 1.[6] $(MH_n^{l\times m}) = n + 4.$

Lemma 1. *Assume* C *is a cycle within a graph* G*; and* σ *is a syndrome on* G*: (1) If* C *is* σ*-zero, then all nodes on* C *are of the same status, namely they are either all fault-free or all faulty.*
(2) If C *is* σ*-nonzero, then at least one node on* C *is faulty.*

Lemma 2. *An* (l, m, n)*-OMMH is Hamiltonian.*

Proof: We prove this lemma by induction on n. We first prove that the result holds for $n=0$, obviously, there is a Hamiltonian cycle within $MH_0^{l\times m}$ with $l,m\geq 3$. Assume there is a Hamiltonian cycle within $MH_k^{l\times m}$ with $l,m\geq 3$, $k\geq 1$. By Definition 1, $MH_{k+1}^{l\times m}$ can be partitioned into two $MH_k^{l\times m}$ notated $0MH_k^{l\times m}$ and $1MH_k^{l\times m}$, and each of them is adjacent to each other, without loss of generality, $v\in 0MH_k^{l\times m}$ and $u\in 1MH_k^{l\times m}$, and u differs from v in exactly one digit position, by the Definition of OMMH, v is adjacent to u. According to assumption, each $MH_k^{l\times m}$ contains a Hamiltonian cycle.

Then we can get a Hamiltonian cycle within $MH_{k+1}^{l\times m}$. The Lemma is true.

The diagnosability of the (l,m,n)-OMMH network under the pessimistic diagnosis strategy

For pessimistic diagnosis (t/t-diagnosable), Chwa and Hakimi provided a necessary and sufficient condition.

Lemma 3 [1]. *Let G = (V,E) the graph representation of a system* S*, with V representing* S*'s processors and* E *the interconnection among them. Then,* S *is* t1/t1*-diagnosable under the pessimistic strategy if and only if for any* $V'\subset V$ *, such that* $|V'|=2p$*, for any* $1\leq p\leq t_1$, $|N(G,V')|\geq t_1-p+1$.

Lemma 4. *For any* $V'\subset V(MH_n^{l\times m})$, $|V'|=2$, $|N(MH_n^{l\times m}),V'|\geq 2n+6$

Proof. We prove the lemma by induction n.For any $V^{'}\subset V(MH_{r+1}^{l+m})$, $\left|V^{'}\right|=2$,let $V^{'}=\{u,v\}$.The basic $n=0$,the claim can be checked by inspection. Assume that the lemma is true in $MH_n^{l\times m}$ for $n=r$,we will prove that the lemma is true for $n=r+1$.then u and v are adjacent or nonadjacent in $MH_{r+1}^{l\times m}$.

Case 1. If u and v are adjacent in $MH_n^{l\times m}$,by lemma 1,we have $N(MH_n^{l\times m},\{u\})\bigcap N(MH_n^{l\times m},\{v\})=\phi$. Then we further have $\left|N(MH_n^{l\times m},V^{'})\right|=\left|N(MH_n^{l\times m},\{u\})\right|+\left|N(MH_n^{l\times m},\{v\})\right|-2=2n+6$.

Case 2. If u and v are nonadjacent in $MH_n^{l\times m}$,then we further consider the following subcases. **Subcase 2.1.**If $u,v\in V(0MH_r^{l\times m})$,by the induction hypothesis, we have $\left|N(0MH_r^{l\times m},V^{'})\right|\geq 2r+6$.

By Definition 1,for $u,v\in MH_{r+1}^{l\times m}$,there exist only two corresponding vertices $u^{'},v^{'}\in V(1MH_r^{l\times m})$,such that $uu^{'},vv^{'}\in E(MH_{r+1}^{l\times m})$ and $u^{'}\neq v^{'}$.Thus.we have $\left|N(MH_{r+1}^{l\times m},V^{'})\right|=\left|N(0MH_r^{l\times m},V^{'})\right|+\left|\{u^{'},v^{'}\}\right|\geq 2(r+1)+6$.Analogously, if $u,v\in V(1MH_r^{l\times m})$,we easily obtain $\left|N(MH_{r+1}^{l\times m},V^{'})\right|\geq 2(r+1)+6$.

Subcase 2.2. If $u\in V(0MH_r^{l\times m})$ and $v\in V(1MH_r^{l\times m})$,then we have $\left|N\left(MH_{r+1}^{l\times m},V^{'}\right)\right|\geq\left|N\left(0MH_r^{l\times m},\{u\}\right)\right|+\left|N\left(1MH_r^{l\times m},\{v\}\right)\right|=2(r+1)+6$. Analogously, if $u\in V(1MH_r^{l\times m})$ and $v\in V(0MH_r^{l\times m})$,we easily obtain $\left|N\left(MH_{r+1}^{l\times m},V^{'}\right)\right|\geq 2(r+1)+6$ .Therefore, the lemma is true for $l,m\geq 3$ and $n\geq 0$.

Lemma 5 [2]. G is a connected graph, for any $V^{'}\subset V(G)$, let $V^{''}=V(G)-V^{'}$.

1) If $\left|V^{''}\right|\geq\kappa(G)$, then $\left|N(V(G)-V^{'},V^{'})\right|\geq\kappa(G)$;

2) If $\left|V^{''}\right|<\kappa(G)$, then $\left|N\left(V\left(G\right)-V^{'},V^{'}\right)\right|=\left|V^{''}\right|$.

Theorem 2. For any $V^{'}\subset V(MH_n^{l\times m})$, $\left|V^{'}\right|=2p$, $1\leq p\leq n+3$, $\left|N\left(MH_n^{l\times m},V^{'}\right)\right|\geq(2n+6)-p+1$ $(l,m\geq 3)$.

Proof. We first can sure that the preceding claim is true for $p=1$ by Lemma 6. Then, we will prove that the assertion is true for $2\leq p\leq n+3$ by induction on n. For $n=0$, we can directly inspect that the assertion is fulfilled. Now, assume the assertion is true for $n=r\geq 1$. Let us prove that the assertion is true for $n=r+1$. Let $V^{'}=V_0\bigcup V_1$, $V_0\subseteq V(0MH_r^{l\times m})$, $V_1\subseteq V(1MH_r^{l\times m})$. Then we can distinguish the following two cases.

Case 1. If $V_0=\phi$, $V_1\neq\phi$,then $\left|V_1\right|=2p\leq 2n+6$ .By the induction hypothesis, $\left|N\left(1MH_r^{l\times m},V_1\right)\right|\geq(2r+6)-p+1$ .Thus we have $\left|N\left(MH_{r+1}^{l\times m},V_1\right)\right|\geq\left|N\left(1MH_r^{l\times m},V_1\right)\right|+\left|N\left(0MH_r^{l\times m},V_1\right)\right|\geq(2r+6)-p+1+2p>(2(r+1)+6)-p+1$.

Analogously, if $V_0\neq\phi,V_1=\phi$,we can easily obtain $\left|N(MH_{r+1}^{l\times m},V_0)\right|\geq(2(r+1)+6)-p+1$.

Case 2. If $V_0\neq\phi$, $V_1\neq\phi$,then $1\leq\left|V_0\right|\leq 2r+5$, $1\leq\left|V_1\right|\leq 2r+5$ .For $0MH_r^{l\times m}$, $\left|0MH_r^{l\times m}-V_0\right|\geq l\times m2^r-(2r+6)>r+4$ .By Lemma 4, we have $\left|N(0MH_r^{l\times m},V_0)\right|=\left|N(V(0MH_r^{l\times m})-V_0,V_0)\right|\geq\kappa(0MH_r^{l\times m})=r+4$ .Analogously, for $1MH_r^{l\times m}$,we can obtain $\left|N(1MH_r^{l\times m},V_1)\right|=\left|N(V(1MH_r^{l\times m})-V_1,V_1)\right|\geq\kappa(1MH_r^{l\times m})=r+4$ .Thus we have $\left|N(MH_{r+1}^{l\times m},V^{'})\right|\geq\left|N(0MH_r^{l\times m},V_0)\right|+\left|N(1MH_r^{l\times m},V_1)\right|\geq 2(r+4)>(2(r+1)+6)-p+1$.

Therefore, the theorem is true for n ≥ 0.By Theorem 2 and Lemma 5, we have the following.

Theorem 2. $MH_n^{l\times m}(l,m\geq 3)$ is (2n + 6)/(2n + 6) -diagnosable under the pessimistic diagnosis strategy.

A fast pessimistic diagnosis algorithm for OMMH

For derivation of the pessimistic diagnosis algorithm of the OMMH, its decomposition property must be analyzed. To achieve the goal, first we decompose an OMMH into subcubes with the same structure. Second, a diagnosis algorithm is provided to adopt every σ-zero cycle conducted by all fault-free nodes to diagnose any σ-nonzero cycle which is adjacent to the σ-zero cycle. Eventually, each node in any undiagnosed σ-nonzero cycle, which is not adjacent to any σ-zero cycle, can be diagnosed in finite steps.

Since $MH_n^{l\times m}$ can be viewed as 2^n-cubes in which 2^n nodes having identical hypercube address form $l\times m$ torus, but the conventional the cycle decomposition method cannot be immediately applied to the $MH_n^{l\times m}$. Let MH^* represent a decomposed proper subcube of an $MH_n^{l\times m}$. A heuristic procedure is derived for decomposing a $MH_n^{l\times m}$ into MH^* for maximizing F, F is the number of faulty nodes. Let cn and N^* denote the order of an MH^* and the total number of MH^* s in the $MH_n^{l\times m}$, respectively. Let $MH^*\times 2^k$ indicate an $MH_n^{l\times m}$ with $|V(MH^*)|\times 2^k$ nodes constructed by 2^k MH^* s in an $MH_n^{l\times m}$, where $l,m\geq 3$, $n\geq 0$. Next algorithm **Procedure-Decom** is formally stated. Obviously, all MH^* s in $MH_n^{l\times m}$ are disjoint.

Procedure-Decom

Input: An $MH_n^{l\times m}$ with $l,m\geq 3$, $n\geq 0$

Output: An MH^*, cn and N^*

Initialization: $N^*\leftarrow 1$, $cn\leftarrow l\times m\times 2^n$, $k\leftarrow 0$, $t\leftarrow n$, $MH^*\leftarrow MH_0^{l\times m}$ (a torus)

Step 1: If $N^*<cn$ then $MH^*\leftarrow MH^*\times 2^k$, $N^*\leftarrow N^*\times 2^k$, $cn\leftarrow cn/2^k$ and $k\leftarrow k+1$ else go to Step 3.

Step 2: if $N^*<cn$ then $MH^*\leftarrow MH^*\times 2^t$, $t\leftarrow n-1$ and go to Step 1.

Step 3: if $cn<F$, then $cn\leftarrow F+1$ and go to Step 7.

Step 4: $cn\leftarrow 1$, $N^*\leftarrow l\times m\times 2^n$, $k\leftarrow 0$, $t\leftarrow n$, $MH^*\leftarrow MH_0^{l\times m}$ (a torus)

Step 5: If $cn\times 2^k<F$, then $MH^*\leftarrow MH^*\times 2^k$, $cn\leftarrow cn\times 2^k$, $N^*\leftarrow N^*/2^k$ and $k\leftarrow k+1$.

Step 6: If $cn\times 2^t\leq F$ then $MH^*\leftarrow MH^*\times 2^t, cn\leftarrow cn\times 2^t, N^*\leftarrow N^*/2^t, t\leftarrow n-1$ and go to Step 5.

Step 7: Output the N^*, MH^*, cn

Clearly, the induced subhypergraph $MH_{cn}^{l\times m}$ by Procedure-Decom is isomorphic to $MH_n^{l\times m}$. Let HC be a Hamiltonian cycle within $MH_n^{l\times m}$, HC can be mapped onto a Hamiltonian cycle within the subhypergraph $MH_{n-cn}^{l\times m}$, which is also a cycle within $MH_n^{l\times m}$. To describe the new diagnosis algorit- hm, we need the following notions.

Definition 2. *$CD(HC)=\{HC(x):l,m,x\in\{0,1\}^{n-cn}\}$, where $l\geq 3$, $m\geq 3$ called a cycle decomposition for $MH_n^{l\times m}$ induced by HC in* ***Procedure-Decom.***

Definition 3. *Let C be a cycle in a cycle decomposition* CD(HC) *of $MH_n^{l\times m}$ and σ is a syndrome on $MH_n^{l\times m}$, then:*

(i) *C is σ-guarded if C is σ-nonzero but is adjacent to some σ-zero cycle. All nodes on a σ-guarded cycle are s-guarded.*

(ii) *C is σ-unguarded if C is σ-nonzero and is not adjacent to any σ-zero cycle. All nodes on a σ-unguarded cycle are σ-unguarded.*

Based on the previous discussions, the pessimistic diagnosis algorithm for OMMH is sketchily described as follows.

Algorithm CD-DIAG-OMMH

Input: An $MH_n^{l\times m}$ with $l,m\geq 3$, $n\geq 6$ .A cycle decomposition CD(HC) for an $MH_n^{l\times m}$ and a syndrome σ on $MH_n^{l\times m}$.

Output:A set F of nodes that are diagnosed as faulty.

Step 1(Initialization): $F\leftarrow\phi, V^{'}\leftarrow\phi, V^{''}\leftarrow\phi$

Step 2: Get a cycle decomposition CD(HC) of $MH_n^{l\times m}$ by applying **Procedure-Decom** given above.

Step 3: For each cycle in $CD(HC)$, decide if it is σ-zero or σ-nonzero by checking all the test outcomes on the cycle. Diagnose all the σ-zero nodes as fault-free. Add all σ-nodes to $V^{'}$.

Step 4: For each σ-nonzero node u, if there is an σ-zero node which is adjacent to u; then diagnose u as fault-free or faulty according as $\sigma(v,u)=0 or 1$. then add u to $V^{'}$ or F according as $\sigma(v,u)=0 or 1$.

Step 5: For each σ-nonzero node u that was not diagnosed in the previous steps, if it has a neighbor v that was diagnosed to be fault-free (that is, u is σ-unguarded but is adjacent to a fault-free σ-guarded node) in the previous steps, then add u to $V^{'}$ or F according as $\sigma(v,u)=0 or 1$.

Step 6: For each remaining σ-nonzero node u, if there is a node v is adjacent to u and diagnosed as fault-free in step 4:(that is, u is σ-unguarded and is not adjacent to any fault-free σ-guarded node that is adjacent to a fault-free σ-guarded node, in turn), then add u to $V^{'}$ or F according as $\sigma(v,u)=0 or 1$

Step 7: Add all the nodes having been diagnosed as faulty to set F.

If $|F|=2n+6$,then return F;

else

$V^{''}=V(MH_n^{l\times m}-F-V^{'})$,then rerurn $(F,V^{'},V^{''})$.

To prove the correctness of this diagnosis algorithm, we need the following lemmas.

Lemma 6. *Let* $l,m\geq 3, n\geq 6$, *Assume* CD(HC) *is a cycle decomposition for* $MH_n^{l\times m}$, *and* σ *is a syndrome on* $MH_n^{l\times m}$ *produced by a set* F *of faults with* $|F|\leq 2n+6$, *Then the following results hold;*

(i) There exists a σ*-zero cycle in* CD(HC)*;*

(ii) All nodes on a σ*-zero cycle are fault-free;*

Proof. Note that $l,m\geq 3$, $n\geq 6$ implies

(i) Applying **Procedure-Decom** on $MH_n^{l\times m}$, $cn\leq N^{*}$, and cn ≤ F-1. Thus , there is at least one cycle that consists of fault-free nodes. By Lemma 1, this cycle is an σ-zero cycle.

(ii)There are totally 2^{cn} nodes on a σ-zero cycle. Note that $2^{cn}\geq 2^{F}\geq 2n+7\geq F+1$. The claim follows from Lemma 1.

Theorem 3. *Assume there are at most* $2n+6$ *faulty nodes in an* OMMH *with* $l,m\geq 3$, $n\geq 6$. *The algorithm can produce a fault set of size at most 2n+6 and containing at most one fault-free node.*

Proof. Lemma 6 (i) assures the existence of at least one σ-zero cycle. This is the start point of this algorithm. Lemma 6 (ii) and the assumptions of the PMC model assure that, upon completion of the algorithm, $S\subseteq V(MH_n^{l\times m})-F$. So all the faulty nodes have been isolated to within the set $V(MH_n^{l\times m})-S$. It remains yet to prove that

$$|V^{''}|\leq 1 \text{ and } |V^{'}|+|V^{''}|\leq 2n+6$$

Clearly, the two inequalities hold for the case where $|V^{'}|=2n+6$. So we assume $|V^{'}|\leq 2n+5$.

Let us have a look at what happens just after **Step 6** of the algorithm has been executed, one of the following three possibilities may take place.

Case 1: All nodes have been identified. Then $|V''|=0$ and hence $|V'|+|V''|\le 2n+6$.

Case 2: There is exactly one unidentified node, say v. Then $V''=\{v\}$. So $|V''|=1$ and $|V'|+|V''|\le 2n+6$.

Case 3: There were exactly two unidentified node, say u and v. Note that this would imply $F\supseteq N(\{u,v\})$ and $|N(\{u,v\})|\ge 2n+6$. Thereby we could conclude $|F|\ge 2n+6$. A contradiction.

Theorem 4. Algorithm CD-DIAG-OMMH runs in O(Nlog2N) time, where $N=l\times m\times 2^n$ is the total number of nodes in the $MH_n^{l\times m}$, where $l,m\ge 3$, $n\ge 6$.

Proof. We analyze the execution time for the algorithm statement by statement.

Step 1 takes O(n) time; **Step 2** takes O(1) time; **Step 3** takes O(N) time; **Steps 4 – 6** takes $O(N\log_2 N)$ time, and **Step 7** takes O(1) time. Therefore, the time complexity of the CD-DIAG is $O(N\log_2 N)$.

Conclusion

In this paper, the diagnosability of the OMMH networks $MH_n^{l\times m}$ under the pessimistic diagnosis strategy based on the PMC model were firstly studied, which was shown that $MH_n^{l\times m}$ is $(2n+6)/(2n+6)$- diagnosable under the pessimistic diagnosis strategy for $l,m\ge 3$, $n\ge 0$. Then, under the PMC model, we proposed an algorithm by exploiting its cycle decomposition properties to diagnose the n-dimensional OMMH. The algorithm runs in $O(N\log_2 N)$ time, where $N=l\times m\times 2^n$.

Keywords: Mobile database; Structure; Agent.

Abstract. With the transaction processing, data query, location query and other functions of mobile devices, the demand for mobile database has also increased. The analysis of the agent-based mobile database structure and the deficiencies of existing systems provide the basis for future research..

Introduction

In a network-centric computing era, it will become the universal demand that people can access information network to obtain the required information at any time and any place accompanied by the rapid development of mobile communication technology, and a large number of popular move equipment have been brought about by the development of economic more and more users are beginning to have a variety of portable computing devices such as laptops, PDAS, personal digital assistant and personal information manager and so on., we call them to mobile computers. Moreover, to support mobile users to access network data and achieve freedom without restraint communications and handling of kinds of business data. The future of mobile computers will be equipped with mobile networking equipment which is mainly based on the wireless network. Then, the concept of "mobile computing" and "mobile database" came into being.

The Mobile Database

User needs and the dual of technological progress make mobile computing as a major expansion of distributed computing. The computing environment which mobile devices via wireless or fixed network connecting with fixed or other mobile device is named mobile computing environments, mobile computing is a distributed computing in the expansion of mobile computing environment [1]. Because of the characteristics of the mobile computing environment, it makes the queries, transaction processing and other issues closely related to the physical location of querying customers, network connections and even the power supply up in the database field, so traditional distributed databases, client / server database can not or can not effectively support mobile computing environment It must be improved by re-design a new database technology, which can comprehensively support mobile computing environment- mobile database.

Mobile database is a distributed database in a mobile computing environment, which is an extension of traditional distributed database system [2]. It can be seen as distributed systems which client is dynamically connected with the fixed server nodes. An ideal mobile database should achieve the following objectives:

Availability and Scalability: to avoid system instability, while providing high availability and scalability;

Mobility: allows the mobile computer to access or update the database in the case of network disconnect;

Serializability: support to meet the serializable execution of concurrent transactions;

Convergence: the system always converges to a consistent state, and thus avoids confusion.

The Key Technologies Mobile Database

Mobile computing provides the research for researchers in the field of database and data management, and then the key technologies of mobile database include the following aspects:

Replication and Caching Techniques

The main purpose of data replication is to improve the distributed database system's availability, reliability, and access performance. Cache technology caches the part of the data through the client,, to achieve the purpose of reducing access to the database server to improve performance. The technology is the key technology to solve the disconnection of the mobile database to maintain the consistency of data. It is also used to patch to adapt the technology of mobile computing on the base of the existing DBMS

Data Broadcasting Techniques

Popularly speaking, data broadcasting is that using the asymmetry of client and server communication to sent data to the client in the form of a periodic broadcast in mobile computing environment. The biggest advantage is that the overhead of broadcast change if the number of mobile users change, with data broadcasting, you can solve the disconnected problem of database system in a cert extent.

The Technology of Mobile Query

In the mobile computing environment, the related updating and querying location information is an important application. Move query is all query technology of mobile database. In mobile database systems, location-based changes to provide the information of location related for the user is an important application.

The Mobile Transaction Processing

Transaction processing is a basic function of database management system. It is mainly used to maintain the consistency of data to support for multi-user concurrent access to make users enable reliably query and update the database. In general, users access the database system is accomplished through the transaction.

Agent Technology

Agent Concept

The research of Agent originated in the field of artificial intelligence. From a broad point of view, Agent shall includes: reactivity, autonomy, social and spontaneous; from the narrow point of view, agent should also have some of the usual human characteristics, such as knowledge, beliefs, intentions, commitments and other mental state[3]. From the above analysis of the agent feature that we can give a simple definition of Agent: Agent is a computer system which is in a specific environment and can sense the environment, enable achieve a goal of designers and users, and can flexibility and independently run computing entity or program in that environment.

Mobile Agent

Mobile agent is a program which can autonomously migrate from one host to another host in heterogeneous network, and can interact with other Agent or resources [4]. Mobile agent has the autonomy, mobility, collaboration, security, intelligence and other characteristics.

The traditional distributed computing is based on Client / Server architecture, its bandwidth cost serious, network load is not balanced, and the fault tolerance is poor. Mobile agent as a new distributed computing tools. Through sending their own code and the state to the remote host and the way of remote host performing overcomes the Client / Server program's shortcomings, is the expansion of traditional C / S model. It adds a new level of an agent between the client and the server. The model is shown in Figure 1.

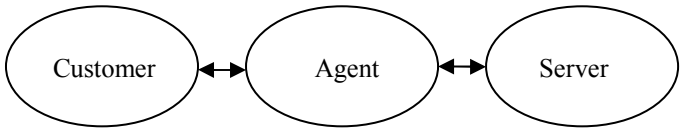

Figure 1: The model of agent-based mobile database

Thus, the agent-based mobile database has the following advantages:

The agent-based system is distributed and asynchronous, therefore, the entire computer environment is open, is extensible;

The agent-based system supports the disconnected operation of mobile clients;

The use of agent technology can significantly reduce traffic flow on the wireless communications network;

Agent resides in the high-speed and fixed network, on behalf of all mobile customers to retrieve every database;

Agent is able to combine the knowledge of client and server, and reasoning on the server, to determine their own work in the next step;

Multiple agents can dynamically adjust the distribution to maintain the optimal configuration;

Agent can reach the server directly to retrieve the final result, to avoid the delay of the middle data transmission.

Agent-based Classification of Mobile Database System Architecture

Agent-based database systems in the mobile location and function, we can be divided into the following categories:

Customer-Customer Agent-Server Structure

In this structure, Customer agent is equivalent to a local server proxy which resides on the local client. Work is: the cached client needs to access the data; the period of disconnection simulates the server's operations in the normal run-time; maintenance all of updates log; to integrate with the data when re-connecting to complete mobile customer's support. These operations are open to customers, so the above procedures do not need to change. Figure 2.

Figure 2: The customer agent-based mobile database structure

Customer- Server Agent-Server Structure

In the mobile environment, users may need server to complete compute-intensive operations. In this case, the limited resources of client can not meet the requirements of cache space, and then you need to set an Agent to collect client needs on the fixed network, summing up requests of multiple clients to submit requests to the server. Server Agent plays the role of a bridge, before disconnecting, the client passes request to the server Agent; after disconnected, the server Agent instead of the client hands request to the server, complete a series of operations; re-connecting, the server Agent will passed the final structure to the client which successfully complete the task. Although this structure can help clients reduce operating, but the user can't continuous access when it's disconnected. Figure 3.

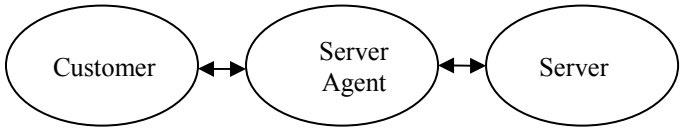

Figure 3: The server agent-based mobile database structure

Customer-Customer Agent-Server Structure

However, in practice, there is only an Agent having definite problems, and no matter which side of this Agent is located, for the optimization of communication is only in one direction, in order to solve this problem, combining the advantages and shortcomings of these two structures, it has developed a couple of application structure of the Agent and divided it into two parts: the client agent can collect user requests, and returns the results to the user, the server Agent is as customers which resides on the local. Thus, the relational task can be handed in both agents to complete. Figure 4.

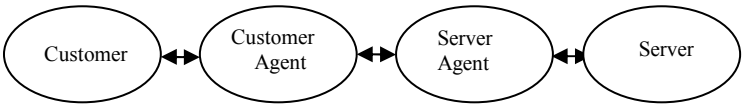

Figure 4: The customer/server agent-based mobile database structure

The structure of these systems, regardless of the location and role of Agent to the customer ,the relationship between client, Agent and server is a linear, and in practical applications, mobile systems are mostly comes from the expansion of distributed systems. The relationship of Server to server, server to client is the network, the server not only to support mobile customers, but also supports traditional fixed clients, multiple servers also need the replication and synchronization of data. In addition, a mobile host may be physically far away from the original host when reconnecting to the fixed network Therefore, these linear structures can't support each other enough for the mobile host moves across servers, autonomy, collaboration and other features We need to be extended to the Agent and the division of functions and further research.

Agent-based Database Architecture.

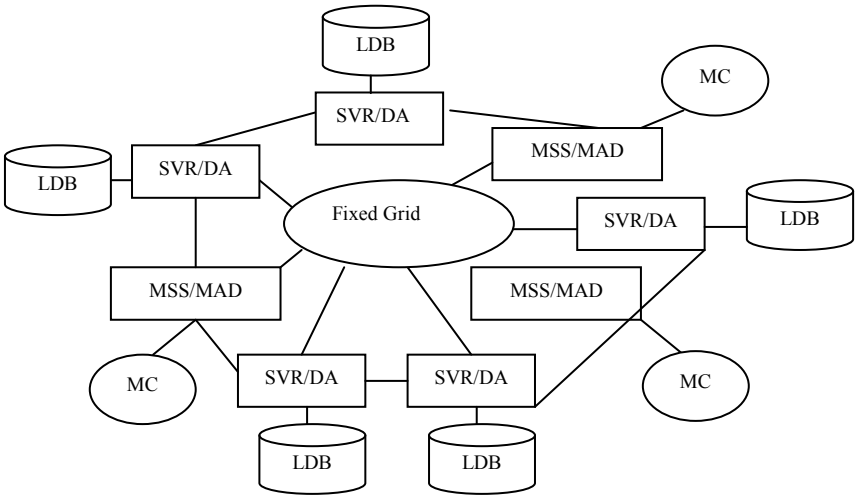

Figure 5 Agent-based mobile database structure

MC: Mobile Client mobile client
MSS: Mobile Support Station
MAD: Mobile Agent Dock
SVR: Server (fixed host to manage local database)
DA: Database Agent
LDB: Local Database

General mobile agent-based data system organization is shown like Figure 5, in this system, the server is generally seen as a fixed node, each server maintains a local database, to retain all requests history on the server; Database Agent is still located on the server Agent, responsible for handling the requests that client accesses to the database directly operate the database. To receive and return the

information of nodes to the client through communicating with mobile Agent; mobile support nodes are in a fixed high-speed network to support wireless network elements, it not only communicates with the mobile client through wireless network , but also communicates with the server through a fixed network; Mobile Agent Terminal is located on the Mobile Agent Management System of MSS. It is based on the client's request to create Mobile Agent, and sends Mobile Agent to the correct address, and receives the mobile Agent which returns from the server, to transfer the results to the appropriate client; mobile clients with mobility and frequent network disconnection.

Summary

With network technology and wireless communication technologies in depth and popularity, more and more users use mobile devices for transaction processing and data queries, location queries and so on. The demand for mobile database has also increased. However, mobile-database's mobility, disconnect, bandwidth limited, network communications of non-symmetry, and power consumption of the limited nature of such features, determine that mobile computing environment must be different from the traditional distributed computing. So, we will seek to solve these issues on the base of Agent study and have innovation on the base of the existing Agent-based.

Keywords: wireless broadcast, cache-based retransmission, network coding, buffer list.

Abstract: Cache-based network coding has been proposed recently as an effective method to improve retransmission efficiency. In this way, the receiver will cache the encoded packets that cannot be decoded rather than delete. However, some cache-based methods neglect the overlap relationship among encoded packets or cached encoded packets. In this paper a new cache-based network coding retransmission scheme in wireless network (CNCR) has been proposed, in which the buffer list of failed encoded packets at the receiver will be updated by simplifying the cached encoded packets according to their overlap relationship. Furthermore the special case " the cross relation " has been introduced, the requested packet in this case will be retransmitted immediately, and the fast decoding of encoded packets cached in the buffer list can be realized. Finally the simulation results show that CNCR can improve the recovery efficiency , and have apparently superiority to previous works proposed.

Introduction

Wireless transmission is bandwidth-limited and high-loss due to the poor quality of the wireless channel. To address this problem, it is necessary to design more efficient retransmission schemes to increase the transmission efficiency . Network Coding [1] (NC) is a new coding technique that can encode the input data in the linear or nonlinear way at intermediate nodes. At present, the retransmission schemes based on network coding have been widely researched and applied [2-5].

That retransmission schemes based on network coding is obviously superior to the ARQ in transmission efficiency has been verified [6], therefore the further research is focused on reducing retransmissions. Xiao proposes a method that encodes the lost packets in their sending order, but the performance of this method becomes worse when a receiver lost more than one packet [7]; Fan introduces a method to reduce the decoding complexity, however, it also reduces the possibility of encoding and increases the retransmissions [8]. The above encoding strategies recover lost packets only through a single retransmitted packet without considering multiple retransmitted packets. Rozner [9] proposes the Efficient Retransmission (ER) algorithm, but it requires all encoded packets should be decoded by all receivers, which wastes a lot of encoding opportunities and leads to the poor performance. Zhan [10] proves that allowing the encoded packets to fail to be decoded at some receivers can effectively decrease the retransmissions, and proposes a Cache-based Multicast Retransmission Encoding algorithm (CMRE). CMRE allows receivers to cache the encoded packets, which cannot be decoded, to facilitate the subsequent decoding. Although cache-based retransmission schemes using network coding [10,11] can decrease the number of retransmissions, they may not be able to take full advantage of the cached and improve the retransmission performance.

In this paper, a new cache-based network coding retransmission scheme in wireless communication networks (CNCR) is proposed, CNCR allows the receivers to cache the encoded packets failed to be decoded, and updates the buffer list by simplifying the cached encoded packets, and requests the lost packets to realize the fast decoding of the encoded packets cached in the buffer list. CNCR can further reduce the number of retransmissions and overhead.

The rest of this paper is organized as follows. Section 1 illustrates the single-hop wireless broadcasting network model. Section 2 presents the details of our proposed CNCR scheme. Section 3 evaluates the performance of CNCR through simulation results.

Network Model

Our model consists of a source node and $N(N>2)$ receivers $R_i(1 \le i \le N)$. The communicating procedure is divided into two phases: the initial transmission phase and the recovery phase. In the initial transmission phase, the source node broadcasts a set $P=\{P_{i,\ldots,}P_K\}$ totally K packets. During this phase, each receiver listens to the requested packets as well as the other packets requested by other receivers. Corresponding to each requested packet, each receiver sends an *ACK/NAK* packet to the source node. At the end of initial transmission phase, the source node maintains a $N\times K$ receiving information matrix T in which each entry $T(i,j)(1 \le i \le N, 1 \le j \le K)$ indicates whether the receiver R_i has successfully received packet P_j or not. $T(i,j)=0$ if P_j is received correctly by R_i and $T(i,j)=1$ otherwise.

In the recovery phase, a packet retransmission scheme is employed to deliver the lost packets to the receivers that requested them until all receivers obtain their requested packets correctly. We define the probability that a receiver R_i loses a packet is P_i and assume that all packets have a fixed length during both initial transmission and recovery phases.

Cache-Based Network Coding Retransmission Scheme

A. p*roblem statement*

Cache-based network coding can be described as follows: during the recovery phase, the source node generates a encoded packet by XORing a set of the lost packets according to receiving information matrix T and retransmits it. Then the receivers recover their lost packets through the encoded packet or cache the encoded packet if the receivers fail to decode it. When the receivers recover lost packets through subsequent encoded packets, they can decode the cached encoded packets and then recover their lost packets.

	P_1	P_2	P_3	P_4	P_5	P_6	P_7	P_8	P_9	P_{10}
R_1	0	1	0	1	0	1	1	0	0	0
R_2	0	1	0	0	1	1	0	1	0	0
R_3	0	0	1	0	1	0	1	0	1	0
R_4	0	0	0	1	1	1	0	0	0	1
R_5	1	1	1	1	0	0	0	1	0	0

Fig. 1: Receiving Information Matrix

Fig. 1 illustrates an example of receiving information matrix with 4 receivers after 10 packets are broadcast. For example, according to a cache-based network coding retransmission scheme named Multi-packet Decoding and Network Coding based Broadcasting Retransmission (MDNCBR) [8], the source node generates four encoded packets :

$C_1=P_1\oplus P_2\oplus P_3\oplus P_4$, $C_2=P_2\oplus P_4\oplus P_5$, $C_3=P_3\oplus P_6\oplus P_7$, $C_4=P_4\oplus P_7\oplus P_8\oplus P_9\oplus P_{10}$, where R_2 , R_3 , R_4 can recover their corresponding lost packets from these encoded packets, R_1 and R_5 cannot decode these encoded packets but cache them. To illustrate the point, the decoding situation of R_1 can be denoted by $(P_2, P_4)|(P_2, P_4)|(P_6, P_7)|(P_4, P_7)$, where the first (P_2, P_4) represents R_1 cannot recover P_2 , P_4 from C_1 ; the second (P_2, P_4) represents R_1 cannot recover P_2 , P_4 from C_2 ; (P_6, P_7) represents R_1 cannot recover P_6 , P_7 from C_3 ; (P_4, P_7) represents R_1 cannot recover P_4 , P_7 from C_4 . Similarly, the decoding situation of R_5 can be denoted by $(P_1, P_2, P_3, P_4)|(P_2, P_4)|P_3|(P_4, P_8)$, where " P_3 " represents R_5 can recover P_3 from C_3 correctly.

As described above, the cached encoded packets in R_1 and R_5 cannot be decoded through the subsequent encoded packets, thus decreasing retransmission efficiency. By observing the above cached encoded packets , it is easy to find there is some overlap relationship among them, which may

lead to failure to decode the cached encoded packets and decreasing the decoding efficiency of the cached encoded packets. This problem raises an important question. How can we find the optimal way to achieve the higher retransmission efficiency by using the overlap relationship among the cached encoded packets.

To address this problem, this paper proposes a new cache-based retransmission scheme to achieve higher decoding efficiency of the encoded packets cached in the receivers.

B. a*ssumptions and definitions*

To describe CNCR scheme proposed in this paper, we make the following few assumptions:

1) The source node broadcasts packets in a time of fixed slots in the initial transmission phase.

2) Assume the packet loss rates of different receivers are irrelevant and follow the Bernoulli trial.

3) The source node can obtain the ID numbers of lost packets, network coding operates in the order of ID number.

4) A receiver keeps a buffer list to cache the encoded packets which cannot be decoded. Receivers recover the lost packets through dealing with the encoded packets cached in their buffer list.

5) The encoding and decoding operations for network coding are bitwise XOR.

Definition 1 If two neighboring encoded packets cached in the buffer list meet the condition, namely all the ID numbers of the lost packets in the former encoded packet are smaller than the latter's is called cross relation.

When the buffer list caches too many encoded packets, it not only increases storage overhead of receivers, but also increases the time consuming to decode these encoded packets, resulting in more transmission delay. For lost packets are encoded in the sequential order of ID number from the smallest to the largest, according to the principle of network coding, if two encoded packets cached in the buffer list meet the cross relation, the lost packet which has the maximum ID number in the former encoded packet cannot be recovered through the subsequent encoded packets. For example, as shown in Fig. 1, at the receiver R_1, the second (P_2, P_4) and (P_6, P_7) meet the cross relation, the lost packet P_4 cannot be recovered through subsequent encoded packets C_3, C_4.The receiver can ask the source node for the lost packet which has the maximum ID number in the former encoded packet so that it can realize the fast decoding of the cached encoded packets.

C. *CNCR scheme*

CNCR scheme allows the encoded packets to fail to be decoded at some receivers. When a receiver fails to decode the encoded packets due to losing more than one packet, the receiver caches these encoded packets, and updates the buffer list by simplifying the cached encoded packets according to their overlap relationship. If the subsequent encoded packets can be decoded to recover the lost packets correctly, put the recovered packets into the cached encoded packets in the buffer list to recover the before lost packets. At the same time, the receivers request the lost packets immediately when the cached encoded packets meet the cross relation, and put the retransmitted packets into the cached encoded packets in the buffer list to recover the before lost packets. In CNCR scheme, receivers recover the lost packets through the cached encoded packets which fail to be decoded, and take full advantage of the cached encoded packets. CNCR scheme effectively improves recovery efficiency and further reduces retransmissions.

The major process of the CNCR scheme is described as follows:

Step 1: The source node broadcasts packets in the initial transmission phase, after K slots, the source node obtains the receiving information matrix T;

Step 2: Search for the first "1" position in each row in matrix T in turn. Put these packets into the coding list, and reset these positions into "0" at the same time;

Step 3: Encode the packets in the coding list in the sequential order of ID number from the smallest to the largest, and broadcast these encoded packets;

Step 4: When the receivers fail to decode the encoded packets, if the buffer list is empty, the receivers cache the encoded packets directly; otherwise, update the buffer list by simplifying the encoded packets cached in the buffer list;

Step 5: If two neighboring encoded packets in the buffer list meet the cross relation, the receivers ask the source node for the lost packet which has the maximum ID number in the former encoded packet;

Step 6: Put the retransmitted packets or recovered packets into the relevant encoded packets in the buffer list, and recover corresponding lost packets.

As shown in Fig. 1, according to CNCR scheme, at the receiver R_5, after updating the buffer list by simplifying $C_1 \oplus C_2$ to $P_1 \oplus P_3 \oplus P_5$, R_5 recovers the lost packet P_1 through $C_3 \oplus P_1 \oplus P_3 \oplus P_5$; at the receiver R_1, the second (P_2, P_4) and (P_6, P_7) meet the cross relation, R_1 ask the source node for the packet P_4; in the end, put the packets P_1, P_4 respectively into the cached encoded packets in the buffer list of R_1 and R_5, recover the respective lost packets.

As described above, using CNCR scheme only needs 5 retransmissions to recover all lost packets, CNCR can effectively reduce retransmissions, and improve the efficiency of retransmission.

Simulation Results

In this section, we compare our CNCR scheme with the traditional retransmission (ARQ), NCWBR approach [8], and MDNCBR [12] algorithm. We evaluate the performance of retransmissions and network overhead, and analyze the experimental data.

The simulator of OPNET is used to simulate the wireless broadcasting network. The simulation scenario consists of a source node and five receivers in the topology structure of 500 m*500 m. The source node broadcasts size of 152bit packets by 1 packet/s to the receivers. In this paper, we design four groups of experiments with changing the number of sending packets with 100,200,300,400.

A. t*he number of retransmissions*

The number of retransmissions is the sum of retransmitting packets and encoded packets. The number of retransmissions is an important parameter of retransmission performance. The retransmissions are less, the packet recovering ability is stronger, and the network coding efficiency is higher. Fig. 2 shows the variation of the number of retransmissions that when the number of sending packets is changed, and the packet loss rates of all receivers are equal to 0.4. Fig. 3 shows the variation of the number of retransmissions, when the packet loss rate is changed, the packet loss rate in the figure ranges from 0.1 to 0.4 with step size of 0.1. As shown in Fig. 2and Fig. 3, the number of retransmissions of CNCR is significantly less than ARQ's and NCWBR's, and slightly higher than MDNCBR's. With the increase of the number of sending packets and the packet loss rate, the advantages are more obvious. Compared with ARQ and NCWBR, CNCR recovers lost packets by caching the encoded packets failed to be decoded, and the number of retransmissions greatly reduces. Compared with MDNCBR, CNCR simplifies and updates the buffer list, improving the decoding efficiency of the cached encoded packets, so the number of retransmissions is less.

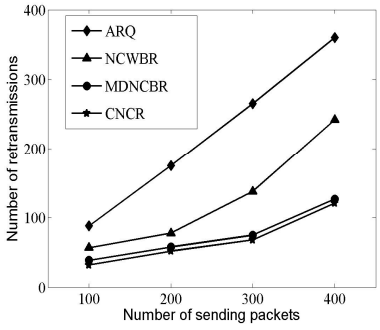

Fig. 2: Comparing of Retransmissions

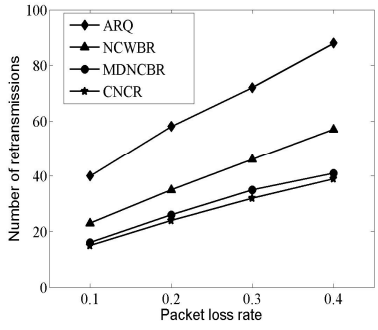

Fig. 3: Comparing of Retransmissions

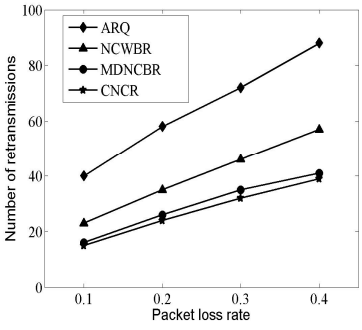

Fig. 4: Comparing of Network Overhead

B. n*etwork overhead*

Network overhead is the sum of the total bits of retransmitting packets, encoded packets and feedbacks. Network overhead is a very important parameter of the network quality. The network overhead is less, the bits used during data transmission in the network are less, thus reducing the link

congestion of transmission and improving the network throughput. As shown in Fig. 4, the network overhead of CNCR in each scenario is the least, due to the number of sending packets is the same, the number of retransmissions is less, the bits transmitted in the network are less. Moreover, MDNCBR and CNCR do not need to send NAK feedbacks in the recovery phase, thus the overhead is further reduced.

Conclusions

A new cache-based network coding retransmission scheme in wireless network has been proposed in this paper. The main contribution of this paper include (a) improving decoding efficiency by updating the buffer list according to the overlap relationship among the cached encoded packets and (b) defining the cross relation among the encoded packets cached in buffer for fast decoding the cached encoded packets. Simulation results show CNCR can effectively reduce the number of retransmissions and network overhead, and then improve the performance of retransmission compared with existing methods.

The Shapes of Products and the Lifestyle With Slow Rhythm

Linsen Guo

School of Art and Design, Nanchang Hangkong University

Nanchang Jiangxi Province China 330063

ncugls@163.com

Key Words: the shapes of products; slow rhythm; lifestyle

Abstract: The lifestyle with excessively quick steps can exert influence on health, and the excessive consumption and the essence of life run in the opposite direction. The lifestyle with "slow rhythm" objects against the excessive consumption and wasting, and advocates the simplified and humanized design, which has something in common with the appropriate "laying down" put forward in Chinese Buddhism. It's the highest wisdom to "lay down" the design with little improvement to the life quality and those unhealthy lifestyles.

Introduction

The shapes of products can exert influence on lifestyle. The current lifestyle is becoming speedier and speedier, but its rhythm with excessively quick steps can have influence on the health, and the excessive consumption and the essence of life run in the opposite direction. The wise man will go after the lifestyle with "slow rhythm" and really enjoy the life.

The Connotation of the Product Shapes

In reality, the product shapes are the transmission of a series of visual symbols. The core idea of the design of product shapes is the coding procession of various symbols, and to take a comprehensive consideration of the visual factors, such as the product shapes, colors and textures, etc. and transmit the product function and embody its features[1].

The shapes of products cover the following three categories: the entity shape, the space shape, and the detail shape. The entity shape is the common appearance possessed by all products and the most direct feeling owned by the observers. But the space shape largely embodies the spirit, especially in architecture. A few thousand years ago, the ancient men sensed the importance of space to the human being. The unreal and real rely on and oppose to each other, and the unreal possesses something real, and vise versa. The connation covered by the unreal and real is limitless, which is always the highest state pursued by the past literati and painters and the west aesthetics can never compare with. The detail shapes can best reveal whether the designer is mature or not. A mature product design usually possesses abundant details, such as the Japanese design, whose details embody the love towards human being; and the Denmark furniture has an extraordinary advantage in detail design, which brings a wonderful reputation throughout the world[2]. Although the excessive emphasis on the details will inevitably cause the complexity, the appropriate details surely can improve the design, which we need to learn from the west.

The Lifestyle

Confronting the various puzzles and crises in the current world, the people have gained a clearer and clearer awareness on the disadvantages present in the traditional developing view. It has been a common sense for the educated throughout the world to step on the way of sustainable development. However, a clear and deep understanding towards the born weak points of the non-sustainable lifestyle characterized by luxury and waste and conforming to the traditional developing viewpoint has not emerged among the people; enough importance has not been attached to and enough research has also not been conducted on the necessity and urgency to transform the traditional lifestyle and establish a sustainable one meeting the need of sustainable development. The sustainable lifestyle is the concrete revealing of the sustainable development in the social life. This lifestyle is the total of various ones not only satisfying the current people's requirements, but also not endangering the future generations to satisfy their needs. Examined from its essence, it involves two aspects of regulations: one is the fit for the material life, i.e. it requires that the material life should start from the human's basic needs, target their healthy living and be strictly confined within the capacity of the earth environment and the endurable scope of its resources. The other one is the consumption level of material, i.e. it not only demands that the persons belonging to the same generation possess the equality on consuming rights, but also every generation , especially the current generation, shouldn't consume the resources at the expense of harming the future ones' consuming rights and developing potentials, but ensure the offspring's sustainable living. At present, it's unavoidable to establish this new type of life concept and lifestyle.

The lifestyle is a culture, and the culture of appreciating beauty in essence is "a typical system of meaning symbols, and similar to a barometer, embodying the social varieties in great details." Thus, it can be seen that the lifestyle and the culture of appreciating beauty can be testified and manifested by each other. Confronting the diversified puzzles and crises in the current world, the human being own a clearer and clearer understanding towards the disadvantages of traditional developing viewpoint. Following the pathway of sustainable development is commonly accepted by the people of all walks. But the people don't have a clear understanding towards the disadvantage featured by luxury and squander and keeping accordance with the traditional developing viewpoint. The sustainable development has a lot in common with the "slow life rhythm" in essence advocated by current men: the "slow life rhythm" objects against excessive consumption and waste but advocates the simplified and humanized design and solving the various conflicts in life with the simplest methods.

The Relationship Between the Product Shapes and Lifestyles

The influence of design style on the lifestyle can best reveal the relationship between them. The industrial design is the focused reflection of economic foundation, social awareness, culture and art, the guiding direction of the trend and the symbol of scientific and technological development. "Being practical, economical, beautiful, appropriate to human being, satisfied with the demands and creative" are the targets and principles pursued by the industrial design. Whatever design methods and styles the designers employ to put their plans into practice, all of them will embody their pursuit for the new social lifestyle.

The Personalized and Diversified Design Style

The current society tends to be high-leveled and multicultural and people's value choice and demand have changed greatly. The changes of value viewpoint and demand desire a better lifestyle, a more comfortable living environment and a higher life quality than any past time provided by the society, which brings the fact that the market is determined by the buyer but not the seller, and the enterprises have to seek for the breakthrough in the design. The current society is "an era with personified products", and the people require that the products meet their personal pursuit and living attitude. So the personified and diversified design style is the best prescription satisfying different leveled lifestyles.

The Style of Conceptual Design

The style of conceptual design is categorized as a leading and fronting one and the imagination of the future. For instance, the conceptual automobile is the concept as "the transporting equipment of loading men" , but not that of " the automobile". And the design of the chair only centers around the concept of "sitting", and not every chair has its own backing cushion. While if it has its own supporting structure and can satisfy the need of "sitting", then it is a practical one. Here, the design functions as the way to improve the planning and guiding of people's lifestyle.

The Developing Trend of Future Product Shapes

Being humanized and multicultural is the main developing trend in the future society and the practice of emotional shape in the product design just follows the need of society development, especially the emphasis on being humanized will in turn help its quick rise in the product shaping and gradually grow up as the developing mode of the future product shaping.

The emotional shape which mainly follows the human being's visual feeling and meets their own entities' psychological and physiological desires can greatly express their emotion and harmonize all relationships[3]. Thus, the emotional shape will surely turn to be the developing trend of the product shaping and the mainstream direction of future industrial design.

The design of "slow rhythm" will become the future mainstream in the design. The original intention of designing is to offer a hand to the life and thus the consumer can leave more energy in the enjoyment of life. However, with the improvement of living standard, the people realize that "the hands" around them are more and more, and even turn to be the obstacles in the life, which is in conflict with the starting point of design. The lifestyle with excessively quick steps can exert influence on health, and the excessive consumption and the essence of life run in the opposite direction. The wise men of life begin to advocate "slowing down a little", which has something in common with the "laying down" put forward in Chinese Buddhism. It's the highest wisdom to "lay down" the design with little improvement to the life quality and those unhealthy lifestyles.

The lifestyle with excessively quick steps can exert influence on health, and the excessive consumption and the essence of life run in the opposite direction. The lifestyle with "slow rhythm" objects against the excessive consumption and wasting, and advocates the simplified and humanized design, which has something in common with the appropriate "laying down" put forward in Chinese Buddhism. It's the highest wisdom to "lay down" the design with little improvement to the life quality and those unhealthy lifestyles.

Application of Traditional Chinese Decorative Patterns in Ceramics Design

Chaoying Ouyang, Yajie Xiong, Lin Li

School Of Arts & Design.HuBei University Of Technology,China

oycyen001@126.com

Keywords: Traditional Chinese decorative patterns, ceramics

Abstract: As an important part of traditional Chinese culture, traditional Chinese decorative patterns, to a great extent, symbolise local customs as well as social, political and economic circumstances of China. Ceramics is of both use value and aesthetic value. Decorative patterns facilitate the latter of the two as a main means. Nowadays, designers are facing a great challenge of how to inherit the aesthetics and the spirit of traditional Chinese decorative patterns and how to apply modern design concepts to contemporary ceramics design. This paper investigates the origins, implications, categorizations and application examples of traditional Chinese decorative patterns in both ancient and modern ceramics designs. Based on the investigation, the paper strives to demonstrate the essence of traditional Chinese decorative patterns, enhance the charm of modern ceramics design, as well as to explore new cultural added value of traditional Chinese decorative patterns.

Introduction

Chinese invented ceramics as early as in the Neolithic Age, which was the product of the smart use of clay and fire. As an evidence of Chinese wisdom and an indispensible part of Chinese culture, ceramics has gone through vicissitudes of thousands of years. It has been a long time since its stories with traditional Chinese decorative patterns started. The connotation and spirit that it has embodied represents the wealth of Chinese national history. Thus conducting a study on traditional patterns is a way of reviving the soul of Chinese nation.

Traditional Chinese Decorative Patterns

Traditional Chinese decorative pattern is one of traditional Chinese arts. It is a form of fine arts that features figures, animals, plants, text, nature, methodology, folktale, proverbs and other topics, with a variety of techniques of expressions including metonymy, analogy, pun, symbolism, and homophone. Embodied with pursuit and best wishes for life, fortune, and well-being , it is closely associated with emotional appeal, cultural background, expression technique and social circumstances in terms of form and implications. Decorative patterns are materialised expressions of people's mind with certain principles of formal beauty.

Traditional Chinese decorative patterns originated from nature worship, worship for stars, sky and sea; totemism , regarding a certain animal or plant as the symbol of the clan; reproduction worship, praising and desiring for the fertility of the biosphere; myths and tales, Nuwa Creating Human, Jingwei Filling the Sea and Kua Fu Chasing the Sun. The evolution and development of traditional Chinese decorative patterns have undergone a very long history. They possess various styles and forms, while retaining to express entrepreneurial spirit and wishes of people.

Traditional patterns appeared as early as in the Neolithic Age. Coloured pottery, which is also called pottery painting, is the earliest example of the combination of pottery and patterns. The Main patterns of coloured pottery are: animal patterns, plant patterns, weaving patterns, and geometry patterns. Among animal patterns, mermaid, fish and fish-bird patterns are the most remarkable. Most plant patterns are revolving and leaf-shaped. As for weaving patterns, they are linear, mat-style, branch, and other kinds. Dots, triangle and abstract patterns drawn with curves are the main styles of geometry patterns . When conveying ideas, primitive humans utilised abstract geometric patterns to generalise with emphasis on emotion expression and the sensibility of the author, rather than for accuracy. After they experienced motion, balance, repetition, strength and weakness, primitive humans expressed them with drawings. There are various approaches of formal beauty applied in decorative patterns such as variation and unification, symmetry and balance, contrast and accordance, paces and rhythm, and others. Due to harsh living conditions, human reproduction was largely influenced by nature. Human beings worshiped reproduction by instinct. Consequently, productive animals like fish and frog became symbols of reproduction. They were presented by primitive humans on patterns to express their desire for fertility.

In the bronze ware age of Xia, Shang and Zhou dynasties, decorative patterns were no longer just simple, primitive, and joyful. Instead, they were used to symbolise the feudal monarchy, and became somewhat solemn and awesome for the reasons of religions and mythologies. Variations appeared like animal face patterns, Kui-shaped pattern, and phoenix-shaped pattern.

Qin and Han dynasties saw the first great unification period in Chinese history when productivity was greatly improved. In pre-Qin period, primitive totems, sorcery and religion were highlighted. While in Qin-Han period, patterns became finer and more colourful. Combination of animal images and co-existence of plants were often used. Lines became smooth, graceful, and dynamic.

"Of the four hundred and eighty temples from the Southern Dynasty, how many are showered in the mist and rain?" This is a line from a poem depicting the prosperity of Buddhism of the period of Wei, Jin, Southern and Northern Dynasties. A great number of Buddhism relief decorative patterns emerged at that time, including lotus pattern, honeysuckle pattern, dragon pattern, and bird pattern. Lotus stands for paradise, honeysuckle immortality, and samsara soul.

In Chinese history the Tang Dynasty was another period of great unification when decorative patterns turned to be a style of magnificence, saturation, sophistication, and heavy colours. Natural lives were often the topic of pattern depiction, for example, rolled grass pattern, Baoxiang flower pattern, pomegranate pattern, etc.

In the Song Dynasty patterns turned out to be more realistic style. Poses of animals in motion and shapes of plants were depicted with dots, lines, and facades. Those materials were flattened and structured in symmetry, making patterns dynamic and elegant.

The Yuan Dynasty was the first dynasty ruled by a minority nation when Mongolian culture, Islamic culture and Han culture co-existed. As a result, the patterns in the Yuan Dynasty manifested the contradiction and fusion, and represented aesthetics of complexity, but also magnificence. Later, the Ming Dynasty saw both existence of freehand and neat style with strong decorative beauty. Notable examples are cloud pattern, stem-twining flower pattern, dragon pattern, phoenix pattern, fish pattern, etc. Close to the end of feudal society, the Qing Dynasty failed to make enough innovation in decorative patterns although there was adequate exquisiteness, as they came in elegant colour and thick lines with strong sense of decoration.

In general, the development and evolution of traditional Chinese decorative patterns started from simple lines expressing human feelings in primitive age. It went on to vary and prosper due to the material and spiritual enjoyment of the court, nobility, and men of letters, and was influenced by

religion thus to evolve in new styles. Considered as an essential part of traditional Chinese culture, the wonderfulness of decoration patterns and their rich implications are beyond description.

Traditional Chinese Decorative Patterns and Ceramic Woks

Use Function and Aesthetic Function

Ceramics is an umbrella name for pottery and porcelain. Its raw material comes from tempered clay, which is abundant on the earth . During the early stages of ceramics, it was used only as convenient utensils until aesthetic function was added to it. Blue and white porcelain, Sancai, and coloured ceramics, with patterns of different periods of history, all imply wealth and power and have thus promoted their value through aesthetic function. Ceramics can be categorised by function as there are daily usage ceramics, art ceramics and industrial ceramics. They all own both materiality, which means the practicability and use value, and the spirituality that emphasises aesthetic value. Their colour, shape, patterns and other elements, are all symbols that brings both visual and psychological enjoyment. Decorative patterns, in particular as the main vehicle of expression of local customs and aesthetics, boost aesthetic value as well as the price of ceramics in a way of arousing resonance and acceptance of people.

Art of decorative patterns has a long history in China. As a symbol of social circumstances and daily life of different periods, it is an irreplaceable record of traditional Chinese culture. Accompanying China in her best and worst times, decorative patterns stemmed from simplicity of primitive ages, to rough style on bronze ware in slave society, and later to exquisiteness in feudal ages. It has evolved into main categories of the following: auspiciousness, geometry, animal, plant and figure, which are embodied with different art styles and aesthetic consciousness.

Pattern design is based on social and economic conditions of the time in question, and is genuine reflections of ancient economic, political and cultural life. For example, the mermaid patterns in primitive society implied an abundant life and reproductions. This is the consequence of harsh living conditions of that time, as daily life, and even reproduction were under constant threat. Later in the Shang Dynasty, class differentiation came into being and thus there were slaves and slave owners. Animal patterns, especially fierce animals, symbolised the awe of slave owner class. During the Southern and Northern Dynasties, people longed for peaceful life as the country suffered long-time chaos caused by wars. Subsequently, Buddhism became popular as people hinged their hopes on samsara. It was believed that sufferings before death result in entry to nirvana in afterlife. Lotus patterns were often seen at that time as the symbol of Buddhism, implying “Sukhavati”, “pureness” and “auspiciousness”.

With the society completing a transformation from one with an elitism culture to a popular one, handicrafts made in exquisite manner and small numbers were replaced by ones made with machines and large quantities. In this process, ceramics shifted from the treasure of the rich and noble to the daily product affordable for ordinary people. In the meantime, it has become a representative modern product, made with controlled cost and with a simple style, instead of the outcome of careful design and sheer workmanship. After the ceramics was commercialised, businesses have continually joined in this trade. The advance of technology and productivity made making it no longer a problem, but it is still a question for businesses that how to make their own product outstanding. On this occasion, traditional decorative pattern, with its unique attractiveness and culture connotation, can give ceramics the special cultural additional value as well as the aesthetic value. Nowadays, designers are facing a great challenge in inheriting the aesthetics and the spirit of these beautiful and meaningful patterns, and also in combining modern design concepts with contemporary ceramics design.

Figure 1, Deer and Crane Enjoying Spring Together on the first facade

Figure 2, Tiger and Mouse patterns on the second facade

Figure 3, Lotus and Shrimp patterns on the third facade

Figure 4, Magpies in a Plum Tree on the fourth facade

Application of Traditional Decorative Patterns Illustrated in a Folk Pottery Pot with Yellow Glaze

Patterns are drawn on the four facades of the pottery. The first facade is a transformed pattern of "Deer and Crane Enjoying Spring Together"; the second an animal pattern of the mouse and the tiger; the third the pattern of the lotus and the shrimp; the fourth the "Magpies in a Plum Tree" pattern which depicts a magpie resting in a plum tree.

On the first facade there is a pattern of the deer and the crane, implying "Deer and Crane Enjoying Spring Together". The phrase is intended to suggest that nature is thriving and flourishing in spring. In Chinese "deer" is homophonic to "land" and "crane" to "together". The images are combined to form the auspicious pattern of "Deer and Crane Enjoying Spring Together". In the way of exaggeration and simplification, the author combined the deer and crane into a pattern. To keep the crane standing higher than the deer in the pattern, the author positioned the crane in the branch and the deer under the tree.

On the second facade is a pattern of the tiger and the mouse. The worship for the tiger is believed to originate from the totem worship for the tiger in Chu culture. The tiger has been regarded as a protector by labouring people since the Han Dynasty as it symbolises bravery and firmness. The first symbolic meaning of the mouse is agility for its keen sense of smell, timidity and wariness. Thanks to its small size of the body, the mouse can always make a successful escape whenever in danger. As a result, the mouse was regarded as a symbol of agility. What's more, the mouse is believed to have foresight of future good and ill luck. The second symbolic meaning of the mouse is vitality. The author added trees to the image to keep its style coherent with those on the other three facades and to highlight the patterns of the tiger and the mouse. By doing this it also makes the whole picture more saturated.

On the third facade there are the patterns of the lotus and the shrimp. In a local slang, the shrimp stands for "smoothness and success" which means the ability to tackle problems and resourcefulness. The lotus has two implications. One is that "the lotus remains stainless after rising from the slimy bed and modest while standing over the clear water". The lotus is a symbol of honest and elegant gentleman. The other is the Sukhavati, which stands for pureness and auspiciousness.

On the fourth facade is a pattern named "Magpies in a Plum Tree". "Magpie" was regarded as a symbol of "happiness" in ancient times, as the two Chinese characters are homophonic. In addition, "plum" is homophonic to "eyebrow". Therefore, a magpie standing in a plum tree depicts the look that delighted people usually show. "Magpies in a Plum Tree" is one of the auspicious patterns frequently seen in Chinese folk arts.

The patterns on the body of the pot are presented on a basis of sections. On the top are the patterns of auspicious-wings and the patterns of transformed twining branch. In the middle are single patterns in detail: the pattern of “Deer and Crane Enjoying Spring Together”, the Pattern of the Tiger and the Mouse, the Pattern of the Shrimp, and the Pattern of Magpies in a Plum Tree. On the bottom is the Pattern of the Box. This pattern, together with the patterns of auspicious-wings and the patterns of transformed twining branches fully surrounds the pot body in two-sides continual and tape shape. Geometrical patterns and figure patterns form contrast and cooperation, making the patterns on the pot look lively and dynamic. The patterns are made both in main and secondary positions as well as in detail and general, thus to present the contrast of expression strength on the pot body and a sense of rhythm. The simple natural handling of the patterns serves as a good example of “great skills seem awkward and extreme sophistication leads to simplicity”. With the rough and simple lines in the patterns the author expressed his wish and love for life.

Conclusion

When applying traditional Chinese decorative patterns in modern ceramics design, modern designers cannot simply copy the originals. Instead, they should combine their works with current social circumstances, trend and aesthetics, as well as traditional Chinese culture, so as to create works in the modern style. Only in this way can the root-seeking complex of Chinese nation be fully expressed and traditional Chinese culture inherited.

Keywords: food and agricultural product, packaging material, barriers

Abstract: Foods and agricultural products safety problems caused by the packaging materials have attracted extensive attention all over the world and some developed countries take it as a technical trade measure to increase the threshold of foods and agricultural products import, which brings about great negative impact to the export countries. Based on the analysis of the packaging material barriers faced by foods and agricultural products export in China, this paper will put forward some countermeasures to break through the packaging material barriers of foreign countries.

Introduction

With the global increasing emphasis on food safety problem, the safety problem caused by the food and agriculture product packaging has attracted extensive attention all over the world and some developed countries take it as a technical trade measure to increase the threshold of foods and agricultural products import, which bring about great negative impact to the export countries. As a large agricultural country, the agricultural product export occupies an important position in the foreign trade of China. Although the export scale of foods and agricultural products in China continues to expand, in recent years the foods and agricultural products export of China is frequently blocked by foreign countries for packaging quality problems, resulting in serious economic losses. Packaging material barriers caused more and more attention. Based on the analysis of the packaging material barriers faced by foods and agricultural products export in China, this paper will put forward some countermeasures to break through the packaging material barriers of foreign countries.

The Packaging Material Barriers Faced by Foods and Agricultural Products Export of China

The foods and agricultural products in China are mainly exported to the United States, Japan, the European Union and other countries. These countries not only put forward more and more strict hygiene requirements for foods and agricultural products themselves, but also put forward higher requirements for the chemical composition analysis of packaging materials and material selection. In order to strengthen the safety management of imported foods and agricultural products packaging, starting from safeguarding national interests, they issued a series of strict technical regulations and measures to become the trade barriers faced by exporters.

They Established the Relatively Perfect Law and Regulation System

The sanitary requirements on foods and agricultural products packaging containers and materials in the United States are embodied in "food, drug and cosmetic" of code of federal regulations, which points out that the foods must be packaged in the conditions of meeting sanitary requirements, the production of foods packaging materials must be based on good manufacturing practice, and the packaging materials contacting with foods and their components must conform to the requirements. In the United States the food packaging material is included in the management scope of food additives and according to the degree that some chemical substances in packaging materials endanger human body by foods, the management of packaging materials is divided into three modes that are free from management, foods additives examination and approval and foods contact substance notification.[1]

European Union established the safety regulations of food packaging materials and carried out the research for the packaging influence on food in the1950's, and so far, it has established a relatively perfect system of law and regulation on food packaging materials. Its food packaging materials management includes the framework regulations, special regulations and separate regulations. The framework regulations stapulate the general principles on the management of food packaging materials. The special regulations stapulate the special requirements of each kind of material listed in the framework regulations. The separate regulations are the special provisions for a certain substance alone.The requirements of European Union for food packaging materials usually include the substance list allowed to be used in the packaging materials, quality specification standard, exposed quantity data, migration quantity data, test and analysis method etc..[2]

"Food Sanitation Law" that was issued by Japan in 1947 mentioned food contact material issues and stipulated prohibiting to produce, sell and use the food containers and packaging materials containing harmful substances. Japan's Labor Ministry may formulate the standards and hygienic requirements of food packaging materials according to the need, and the standards of food packaging materials issued by it are divided into three categories. The first is the general standard that stapulates the content requirements of the heavy metals , especially the lead content requirement, in all food containers and packaging materials. The general standard also stipulates that the synthetic pigment used in packaging materials must be approved by Labor Ministry. The second is the category standard that formulates the category standards of metal cans, glass, ceramic, rubber and other substances and the standards of thirteen kinds of polymers. The third is the standard for specific purpose that is formulated for the materials with specific purposes.[3]

They Introduced the Risk Assessment to Evaluate the Safety of New Materials

In addition to considering the structure and properties of the packaging materials themselves, they make a migration simulation test with their contact products to evaluate the effect of packaging materials on agricultural products and foods safety. The code of federal regulations in America stipulates that the materials contacting foods must comform to the provisions of Food and Drug Administration and pass the chemical composition test and migration test. The migration test is used to evaluate the content level of food residue from packaging materials and is the required test of new packaging materials. According to the regulations of Food and Drug Administration, when the substances that can not be used as food ingredients and are harm on human health are used for food field, they must be proved to be no toxic through accurate chemical data and deduction. However, in Europe all materials must go through the very strict toxicity assessment no matter whether the number of migration or having the possibility of migration.[4]

They have Other Provisions of Foods and Agricultural Products Packaging Materials

European Union formulated the maximum migration value of food packaging printing ink and stipulated that the general migration limit of 4 - methyl diphenyl ketone and diphenyl ketone in the food packaging printing ink materials must be less than 0.6 milligrams per kilogram. "Food Sanitation Law" of Japan clearly demands that food packaging can not be too garish and the special ink that is stable and not easy volatile to generate harmful substances must be used to print food packaging.[5]

The United States demanded to evaluate the risk of bisphenol A and prohibited containing it in food and beverage containers through Food Safety Enhancement Act in 2009. France also has the same provisions. France announced that the non-biodegradable plastic packaging materials would be replaced by the environmental degradable materials to package the foods and the agricultural products since January 1, 2010.

In addition, most developed countries have higher standard on the tractability and the recyclable rate of agricultural products packaging materials in their environmental regulations. They require to use the green packaging material that can save energy, reduce waste, recycle or be easy to decompose naturally after being used and not pollute the environment. They carry on the quarantine of hygiene and animals and plants to the packaging produced with natural materials.

The Countermeasures to Break through the Packaging Material Barriers of Foods and Agricultural Products

Though the increasingly strict regulations and standards on the packaging materials of foods and agricultural products in foreign countries promote the foods, agricultural products and packaging industry in China to develope more healthily, safely and environmentally, they have the negative impact on the export of foods and agricultural products of China. In order to deal with increasingly strict packaging material barriers of foods and agricultural products in foreign countries and expand exports, we advise to take the following measures.

Exert the Macro-control Function of Government

Use the successful experience of developed countries in the foods and agricultural products packaging industry for reference, the government should do the following things. Firstly, establish and perfect the foods and agricultural products packaging regulations. China has not the packaging law. Secondly, constantly update and improve the foods and agricultural products packaging standard system so that the packaging materials of foods and agricultural products have the definite standard and speed up the packaging materials standardization. In the fields that the country has not yet established a unified standard, such as ink field of food packaging, establish the new standard and inspection method to be beneficial to supervise the ink market of food packaging.Thirdly, the relevant functional departments of government should strengthen cooperate to further explore and implement the long-term mechanism of food safety supervision, to intensify the supervision of all aspects of export foods and agricultural products and their packaging materials and to strengthen the traceability system construction of quality safty of export foods and agricultural products and their packaging to ensure quality safety of export foods and agricultural products and their packaging. Fourthly, establish and perfect the warning mechanism of the packaging material barriers of export foods and agricultural products as soon as possible, and strengthen the notification and consulting website construction to issue warning information timely for the enterprises.[5]

Strengthen the Guidance and Coordination Function of Industry Association

Firstly, strengthen the communication between the packaging industry and the food and agricultural product industry to combine packaging design, production and application organically. Secondly, through the establishment of integrity system, realize the self-supervision of industry to promote the sustained and healthy development of the whole food and agricultural product packaging industry. Thirdly, actively collect relevant information, timely update, and establish the perfect information disclosure channel. Through the internet and other means of information dissemination, make the domestic export enterprises understand packaging materials related information of other countries as soon as possible.

Improve the Enterprises' Awareness of Quality Safety of Foods and Agricultural Products Packaging

Export enterprises should improve the awareness of quality safety of foods and agricultural products packaging to ensure their own quality safety of foods and agricultural products and to ensure the quality safety of export foods and agricultural products packaging. Export enterprises may take the following measures. Firstly, pay close attention to and deeply understand the packaging materials regulations of foods and agricultural products of other countries and formulate corresponding measures according to the enterprises' situation. Secondly, strengthen the awareness of environmental protection, increase the investment of science and technology and develop non-toxic, harmless and biodegradable green packaging materials to insure the process from raw material purchase to product manufacturing to accord with the environmental protection requirements of import countries. Thirdly, actively develop new markets and implement the diversification strategy of export markets to avoid packaging material barriers of foods and agricultural products and strengthen enterprises ability to resist packaging risks.

Summary

In order to avoid the threat of packing materials to consumer health, Europe and the United States have enacted the strict laws and decrees of foods and agricultural products contact materials safety, which become the trade barriers faced by the export enterprises of foods and agricultural products and make the export enterprises suffer huge economic losses. The government of the export country, the industry association and the enterprises need to work together to cope with the packaging material barriers of developed countries and to guarantee the economic benefits of export enterprises and consumers' food safety.

Safeguard System on the Quality of Excellent Engineers Training

Changming Liu

Yangtze University , Jingzhou, 434023, P.R. China

Keywords: Excellence Program; Excellent Engineers; Training; Quality; Safeguard System

Abstract. Based on literature research, this study proposed a topic on the safeguard system of quality of excellent engineers training. Four safeguard elements of training quality are elaborated, namely, faculty building(premise), collaboration with enterprises(key point), governmental support(guarantee) and the participation of students(basis). Likewise, basic knowledge structure, engineering capability training and engineering accomplishment cultivation are safeguard elements of training quality. Meanwhile, the construction of collaboration, control of practice, improvement of safeguard mechanism and the fulfillment of participating members are safeguard conditions of training quality. It is concluded that Excellence Program can be achieved and effective by constructing the safeguard system of training quality and serious process control.

Introduction

According to the Outline of Mid-long Term Educational Reform and Development, the Ministry of Education put up the Training Program of Excellent Engineers (Excellence Program for short). By 2012, 130241 students, from 824 undergraduate programs or pilot classes and 288 graduate programs in 194 universities, had participated in Excellence Program. The participating universities accounted for 19.1% of those universities with engineering courses. All universities with strong industry background were involved in Excellence Program. The promotion of Excellence Program facilitated the deep reform of university engineering education. It also attracted the attention of relevant ministries and local government to notice and support the educational reform of university. Excellence Program is just unfolding and plays an important role in this reform. However, it is a problem worth to be noticed and discussed on the smooth implementation of Excellence Program and guarantee of engineers cultivation quality.

Safeguard Basis on the Quality of Excellent Engineers Training

There are some elements that quality and effectiveness of Excellence Program largely rely on.

Premise—Faculty Building

Excellence Program aims at cultivating reserve talents of engineering with engineering knowledge, capability and achievement. To improve students' engineering capabilities and achievements, teachers with such talents come first. Therefore, the implementation of Excellence Program primarily requires a group of reasonable-structure, high-quality and good-capability teachers with rich engineering experiences. The group should consist of faculty with engineering practice and research capability. The members of this group can be further divided into two subgroups. One subgroup should have university teachers with good educational experiences and engineering background. The other subgroup should be made up of experienced engineering staff who can give educational instructions. Therefore, there are important tasks, such as electing,

cultivating and constructing a double-structure group of teachers, for universities to apply for Excellence Program.

Key Point—Collaboration with Enterprises

Cultivating reserve talents of engineering needs the participation and collaboration of enterprises, which is a key to the implementation and effectiveness of Excellence Program. Universities applying for Excellence Program should have deep cooperation with enterprises. In other words, those universities should have long-term cooperation with relevant enterprises, learning of their talents requirements and fully absorbing their advice of talents cultivation. Meanwhile, universities applying for Excellence Program are supposed to take advantage of human resource and material resource of enterprise to cultivate students' engineering awareness and capabilities. Under the instruction of the Ministry of Education, universities should maintain long-term cooperation with mutual benefits and correspondingly cultivate reserve talents of engineering. Without the participation and collaboration of enterprises, universities could not succeed in applying for Excellence Program.

Guarantee—Governmental Support

Excellence Program is an engineering talents cultivating program proposed by the Ministry of Education against the background of social development of economic construction. The promotion and implementation of this program involves in initiative of universities, full participation and cooperation of enterprises, as well as support and coordination of government. The local government should enact some policies and measures to encourage enterprises to participate in Excellence Program. Enterprises can be a bridge and band in the implementation of Excellence Program. They can also play a leading role in this program. The smooth implementation of Excellence Program can be achieved with effect only by creating conditions for the cooperation between universities and enterprises. Finally, large quantities of reserve talents can be cultivated and serve for the development of economy and society through this program.

Basis—Students' Participation

The premise of the implementation of Excellence Program is the warm participation of students, regardless of universities' emphasis, enterprises' input or governmental support. Universities should explain the original intention and spirit of Excellence Program to help their students learn the significance of this program and how enterprises can benefit from it. Then, students can be more confident and active to participate in this program. Only when students actively participate in this program as the program required can Experience Program be smoothly implemented. Therefore, it is a premise and basis of Excellence Program to change the program into students' self-requirements and fully motivate their subjective initiatives. Otherwise, the program is with no sense.

Safeguard Elements of the Training Quality of Excellent Engineers

The cultivation of reserve talents of engineering needs to clarify basic elements of talents quality—an important link to ensure the training quality of talents. Otherwise, Excellence Program can not be successful without clear goals and standards. So, what quantities an excellent reserve talent of engineering should have?

Basic Knowledge Structure

The talents-orientation of the Excellence Program needs to satisfy the reality and future demand of economic and social development, meeting the requirements of employers on the knowledge, capability and quality of talents. Due to the diversified types of disciplines and different industry backgrounds, universities applying for the Excellence Program can be different in talents cultivating levels, types and goals. Therefore, according to the service requirements of talents, each university should fully take advantage of talents cultivation to train high-quality excellent engineers by closely cooperating with relevant enterprises and industries. However, wherever the engineers are from, they all need some basic knowledge structures, such as humanistic knowledge, mathematical knowledge, economy knowledge, management knowledge and technological knowledge.

Engineering Capability Training

Engineering capability training is the most important task because the aim of Excellence Program is to cultivate reserve talents of engineering. So, what constitute the engineering capability? At least, it includes engineering design capability, engineering construction capability and engineering management capability. Engineering design capability refers to the combination of the overall conception capability, application capability of new technology, practice capability of new idea and design capability of new plan. Engineering construction capability can change design drawing into engineering entity, which includes the understanding of design thinking and design intention, revise of design alternative and realization of design drawing. When encountering practical engineering problems, engineering construction capability can be beneficial to the solutions of these problems. Engineering management capability consists of dispatch of constructors, control of construction schedule, check of construction quality, security of construction safety, choice of construction material, application of construction technology, optimization of construction process and control of construction cost.

The acquisition of all these mentioned capabilities is a process needing to be understood and accumulated in engineering practice. Therefore, it is the core of Excellence Program to strengthen engineering practice.

Engineering Accomplishment Cultivation

Engineering knowledge and engineering capability are basic tools for an excellent engineer. However, only knowledge and capability are not enough. An excellent engineer should also have good engineering accomplishment. It refers to the accomplishment of identification of engineering value, design of engineering proposal, innovation of engineering technology, management of engineering talents and exchange of international cooperation. The identification of engineering value requires acute identification and assessment of social value, ecological value, environmental value, energy value and development value. The identification process is supposed to provide assessment advice for engineering decision-making in order to guarantee the accuracy of feasibility study. Based on the identification process, the design of engineering proposal ought to make a plan for overall scheme, recruiting scheme-making staff and arranging the research and draft of scheme. Fast choice, revise and perfection of scheme can make high-quality engineering proposal. The innovation of engineering technology elaborates new ideas, technologies, material and equipment as many as possible in the process of engineering scheme and implementation. The management of engineering talents requires recognizing, choosing, cultivating and employing different kinds of

engineers. Discovering talents and putting them in place can enhance the efficiency of talents employment. The exchange of international cooperation means to have knowledge and skills of international shared as well as to understand international engineering discipline and regulations. Qualified engineers should have the ability to equally communicate and negotiate with their international counterparts. They even need to launch a lawsuit with necessary.

It needs practical foundation for the acquisition of knowledge, ability and accomplishment. Excellent engineering capability and accomplishment can not be formed without engineering practice and training. Therefore, engineering practice and training are key links during the cultivation of excellent engineers, guaranteeing the quality of excellent reserve talents of engineering.

Safeguard Conditions of Excellent Engineers Training

To insure the quality of excellent engineers training, the following conditions are needed:

Building Cooperation Mechanism

To build good cooperative relationship with enterprises, universities should ensure both sides benefiting from cooperation under the principal of reciprocity and mutual benefit. In other words, universities should actively take their interests into consideration as enterprises do. Meanwhile, universities should help enterprises overcome the technological problems in production process and provide technological innovation, reform and invention for them. Then, enterprises can get concrete benefits. Therefore, an interests-driven mechanism should be built in the course of cooperation. Full fusion of emotion and adjustment of economic leverage will promote further development and continuation of cooperation.

Controlling Practical Process

Practice training is key link during the cultivation of excellent engineers. Only by exercising engineering practice can Excellence Program be functional in cultivating reserve talents of engineering. Firstly, controlling process requires that practical training time needs to be more than one year. Secondly, controlling process allows students to be involved in engineering practice and to get introduction from engineers. Thirdly, in order to strengthen training effectiveness and training quality, an inspection mechanism should be built to check the time, place, tutor, content and skills of practice.

Perfecting Safeguard Mechanism

Excellence program, a national campaign, needs corresponding national safeguard mechanism, such as laws, policies and talents. China should enact educational regulations on rights and obligations of university and enterprise in the course of talents cultivation as soon as possible. Laws and policies should explicit the role set of both sides, especially for the role and responsibility of enterprise in the course of educational cooperation. Favorable treatment, such as tax allowance and exemption, technological support, patent application and staff training, are also supposed to be included in laws and policies. Then, the initiative of talents cultivation can be enhanced while the quality and effectiveness of Excellence Program can be ensured.

Participation of Relevant Parties

The smooth implementation of Excellence Program requires relevant parties to have mutual cooperation and down-to-earth working style. During each course, relevant parties should take the every session of program seriously and provide reserve talents of engineering best training on knowledge, capacity and achievement. Then, Excellence Program can be in practice with effect.

Keywords: General Arrangement, Methodologies, Layout Design, Early-Stage Design.

Abstract: This paper presents an overview of ship general arrangement design methodologies and philosophies and early-stage design capabilities, particularly during the last decade. The arrangement of a ship has a unique feature in that it can both enable successful shipboard operations and constrain the performance of all subsystems. Stable ship layout is critical to producible, and therefore cost effective, designs and time. This paper overviews the efforts made by the researchers in the last decade to improve generating the arrangement rapidly . Also, identify areas of the ship general arrangements process that are insufficiently addressed or not addressed at all in order to keep pushing the field of general arrangements forward.

Introduction

Over the past 60 years, the cost of new naval ships has outpaced consumer product inflation by a significant margin. Of the 7-11% growth in cost, about half has been attributed to customer-driver, rather than economy-driven, factors [1]. About one-quarter of the increase for surface combatants is due to complexity. The ship's mission requirements, its constituent systems, and the layout of those systems are key factors in the overall complexity of a vessel. From the naval architect's perspective, mission requirements and system selections may be non-negotiable. The remaining lever for managing a ship's complexity lies in the ship's arrangement. General arrangement design, as a system engineering process, is a unique blend of experience and judgment combined with the systematic evaluation of performance. Its objective is to optimize the ship as a total system. The product of the process not only is a representation of design decisions, it also serves as a focal point for establishing an effective dialogue within the design community and also with the operational community[2].

In the field of naval design, the study of concepts and theories in generating general arrangement of these complex engineered systems at an early stage of design (preliminary design) and factors affect decision makers has a serious attention. The need for the naval architect, at the formative preliminary design stages of a ship design, to have a clear understanding of the issues affecting configuration has become more important, because of the risk that the readily available design tools enable the novice ship designer at his/her personal computer all-to-readily to produce what appear to be worked up ship design solutions. In order to motivate the progress in this field we should begin to focus on the philosophy of different methodologies taken by last researchers, and on the points naval architects should keep in mind. This article will handle those two directions, the factors affect them, and the challenges facing each approach. to enrich advantage of the article ,four issues are considered to merit further attention in future considerations.

Design Considerations for the Naval Architect Affect the Early-Stage Design [3]

Vehicle type-Monohull superstructures are more constrained in volume and area than catamaran superstructures. Catamaran side hulls are normal quite cramped and demand a linear, fore-and-aft arrangement[4]. **Vehicle size-Generally**, larger vehicles provide more options arrangements. **Operational environment-Expected sea state**, temperatures and wind loading determine the need for items such as additional insulation, bulkhead strengthening, and viewing options, all of which impact the arrangements. **Operating requirements**-Considerations include operating speed, expected traffic conditions and whether the vehicle is expected to remain at sea during storms. Harbor tugs, for example, feature raised pilot houses with windows in three or four sides, and at times in their overhead, as a way to maximize visibility while ship handling at close quarters in a congested harbor. However, their freeboard (distance from the water to the deck) is low, because there are no storm waves in the harbor **.Type of cargo**-Containers dictate a cargo arrangement built up of rectangular elements ,petroleum dictates double hulls, vehicle ferries must have gently sloping ramps for driving on and off **.Physical security and control**-Security for combatants can include armor for critical compartments and the bridge, which constrains arrangements. Security for commercial ships can include ways to make boarding by pirates difficult. Ferry designs may include limited access openings to better control the entry and exit of passengers **.Type and quantity of personnel aboard the vehicle**- Arrangements vary from spacious, with gracious continuity in flow for luxury yachts and cruise liners, to compact and cluttered in combatants. Special arrangements are needed for handicapped persons, and for male/female crew members, as well as officer/enlisted [5].**Type and size of equipment, and requirements for its at-sea maintenance, access and disassembly**-Propulsion and cargo handling equipment often determine key aspects of arrangements, such as air intakes, exhausts and structural foundations. Extra volume is needed around equipment if at-sea repairs are envisioned **.Sources of noise and vibration**-Personnel living and working spaces are located as far as possible from sources noise and vibration in order to enhance operator performance and personnel comfort [6] **.**

Ship General Arrangement Methodologies and Generating Philosophies

Functional Arrangement Design [7],The philosophy of this method is juxtaposition of what were drafting tables, so that those designers working up the upper decks and superstructure could better interface with the outboard profile designer, while those responsible for the lower deck arrangements interfaced with the inboard profile design. In modern practice this approach translates to the necessity for the ship designer to ensure that 3-D models of compartment locations are considered not just in terms of a given deck arrangement but also of the relationships with adjacent decks and the topside.

Stylised Layout [8],design of specific functions of machinery, living, working, payload, services and liquids, with the object of avoiding excessive interaction between functional areas which could lead subsequently to loss of design control. Produced as a means of maintaining coherence in ship layout.

Outlining Ship Systems[9], a basis for “logical selection of design configurations within boundaries of the feasibility envelope”. Each arrangement was then individually evaluated for a range of parameters, such as ease of modernisation and conversion, modularity and minimisation of vulnerability and topside clutter. Its philosophy to outline the ship design to five systems ,that is containment, mobility, ship support, mission support and human support.

Arrangement Design Methodology, a sequential approach constrained by the initial concept design output and hull form plus subdivision of the decks and bulkheads. They [10]stated that architectural layout programs were examined for their potential for application to ship layout, but could not deal with ship shape and space limitations; also, optimisation techniques were infeasible because of the large number of independent variables involved in ship layout. They provided an update of General Arrangement CAD system.

Creative Ship Design , using the disposition of the principal spaces in the ship to determine both the initial sizing of the ship and the selection of hull dimensions and form parameters[11]. its philosophy, establish a method of using damage stability and structural continuity considerations to determine main transverse bulkhead disposition and thereby controlling the evolution of the general arrangement, within a previously determined envelope of the hull form.

Integrated Synthesis [12],allocating the various compartments of the ship sequentially. The philosophy point to this sequence was not suggested as the recommended way of obtaining the layout, but rather as a suitable start point for an integrated synthesis to take and to utilise the ship arrangement, produced by such a sequence, to size, dimensionalise and select form parameters. It was also argued that with integration of the ship architecture with weight, space and form parameters, a better initial design solution could be achieved, since a more comprehensive initial design description: [13] a) Would provide a better basis for initial cost tradeoffs and parametric selection; b) Could be used to explore alternative layouts, while the hull form and dimensions were still fluid;. c) Could be readily altered, both as regards layout disposition and the consequent hull dimensions and form impact.

Circle of influences [14], classifying the compartment relationships and thereby yield a 3-D block layout, around which a hull form could be “wrapped”.

Intelligent Ship Arrangement (ISA)[15,16,17], focuses on arranging spaces into pre-defined structural zones. its philosophy “to provide an optimization technology and design tool to assist the arrangements designer to create effective, rationally based surface ship arrangements with the maximum amount of intelligent decision making support”. Secondary goals relate to the capture and application of Navy requirements and best practices and to the objective comparison of alternative layout configurations. ISA was developed to assist designers in creating layouts at the end of the conceptual design phase (Analysis of Alternatives, AoA) and at the beginning of preliminary ship design phase[18].

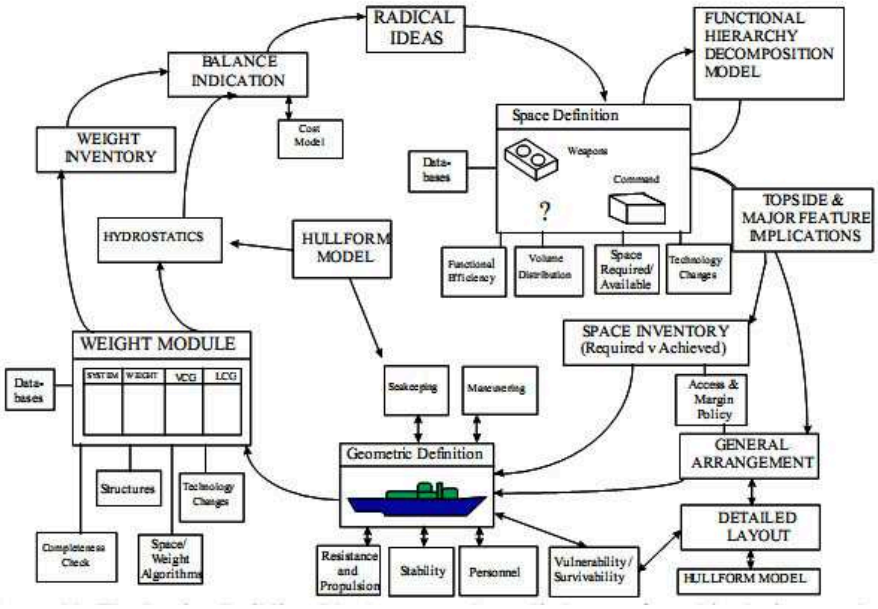

Fig 1: The Design Building Block approach applied to surface ship design synthesis.[22]

Design Building Block(DBB) [19,20,21],its philosophy in combining three systems of computer graphics that incorporation within an existing and established computer aided ship design system will integrate ship architecture into the initial ship synthesis. the system (PARAMARINE) took the essential naval architectural capabilities of the (GODDESS) system and reconfigured them into an object-oriented configuration, executable on modern personal computers [20]. This system was then able to accept a new module, known as (SURFCON), which implemented the Design Building Block approach in a fully integrated manner. The DBB approach has been applied on a surface ship, Fig 1.

The facility of an information rich three dimensional representation of a new ship concept, when integrated with a proper naval architectural numerical description, means the ship designer is able to explore many issues that traditionally were difficult to consider with a purely numerical description and, possibly, a separate sketch or profile. With this integrated representation, the concept designer is able to undertake a greater range of studies, better address innovative and novel options and investigate issues previously left until later in the design process. With such a tool the designer can produce concept descriptions that are able to move more smoothly into the later design phases when much more detailed graphical representations [23].

Packing Ship Systems [24,25], developed a design tool that automatically generates a large number of feasible designs by packing systems into a positioning space. The intention of the tool is to increase the detail of a design in the conceptual design phase whilst maintaining a high level of design flexibility. This allows for more prediction tools to be used in this early stage increasing the knowledge about the concept designs. In the tool objects and clusters of objects (systems, spaces, and components) are defined as building blocks which can be placed into a positioning space. By using different object types (i.e. envelope, subdivision, hard, soft, and logical) the designer of this method is able to make a detailed parametric description of the vessel which a search algorithm can alter. The parametric model allows for large changes to the entire design (e.g. hull, superstructure, decks, bulkheads, etc.) thus maintaining the desired flexibility within the design [26].

Network Science Approach [27] , developing a method to generate and analyze 3-D distributed system and compartment arrangements without designing a ship. Its philosophy shows in the following steps, First, network concepts of centrality and hierarchy are used to highlight and rank the

embedded drivers of an early-stage arrangement prior to developing spatial layouts by directly analyzing the relationship network in a methodical and holistic manner. Second, a network partitioning method is used to cluster shipboard elements into communities of mutually-compatible elements to minimize the degradation of other items located in the same region of the ship. These communities can form the basis of functional zone definitions. Varying the number of partitions reveals a multi-scale depiction of the relationship network. Third, the communities are assigned to structural zones based on cumulative zone preference values. Finally, two new visualization techniques help designers establish connections between the network of inter-element relationships and spatial ship arrangements.

The integration of personal movement [28]**,** an innovative approach to ship design for operation which integrates human factors, operability and personnel movement simulation into the design process. Its philosophy concentrates on integrating operational issues in preliminary ship design and on the implications on the design process undertaken using the Design Building Block approach [29] to preliminary ship design, using the software tools (PARAMARINE) and (maritime-EXODUS) together with a set of software tools called (Demonstrator) a rapid trial and error technique.

The Development of Ship Arrangement Methodologies

The development path, which consist of three methodologies: manual design "optimization," computer-based optimization, and post-processing sets of feasible solutions.

Manual optimization, The traditional approach to ship arrangements includes drawing deck plans by hand, either on paper or within a generic computer aided design tool [30,22]. The hierarchical procedure of defining main compartments, followed by more refined functional compartment definitions, and lastly systems, as the only practical approach to the complex layout problem.

Computer-based optimization, With the development of more powerful computers, semi-automated approaches were developed to increase the number of designs that could be generated and evaluated. The premise is that computers can generate and grade layouts faster than a human can. Elemental information and basic thought processes utilized in the manual approach were captured in database format, and rational evaluation mechanisms were developed [31,23,24]

Post-processing the "best" designs, An experienced naval architect is assumed capable of identifying a quality layout upon seeing it, and therefore, different mechanisms have been developed to keep the designer involved. Rather than simply accepting the single highest-scoring solution from an optimization, a set of high-quality solutions are retained to be analyzed by human designers. [25,32] have developed post-processing tools that allow designers to infer relationships and understand compromise decisions through rapid comparison of the set of potential solutions Fig2 .

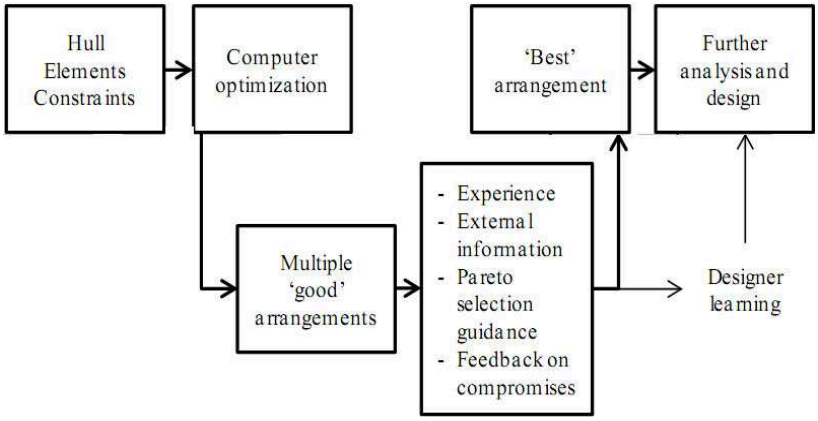

Fig 2: Computer-based optimization with designer selection (right). [26]

Discussion

The following issues are considered to merit further attention in future considerations:

Issue1: Arrangements are the heart of the human factor program of marine vehicles, at every stage of the design, naval architect is involved. because of the preliminary ship design is a multi-criteria process, The architect should consider some of the criteria that can be considered as being part of the important issues driving the design evolution (human factors , user behavior and layout style...) and integrate it into early design. This allows him relative to his expert, to perform a considerable design drivers and solutions when the design is still evolving and opens up the possibility of changing the way in which the designer progresses a design .

Issue2: the previous methods, each one has its own unique way of tackling the ship system arrangement and configuration problem. some deal with the area and others with volume, not all handled a full ship arrangement and analysis. the combination and interaction of those methods and philosophies, developing of a new arrangement tools, design a new optimization algorithms, will lead to create new approaches to general arrangement.

Issue3: advancements are needed in the following areas of the ship general arrangements process: The ability to capture knowledge in an natural manner to facilitate maintenance and reuse of that information. The ability to understand the nature of ship arrangements on a macro-scale and to define appropriate metrics to provide insight into non-dominated solution sets and guidance for down-selecting designs. The ability to view the requirements elucidation process, and the role of ship layouts in that process, as an overlay of multiple data types in order to preserve the richness of information that is lost when mapped in the domain of traditional general arrangements drawings. The ability to provide users with efficient, natural tools for generating and evaluating general arrangements to promote designer exploration and learning and to reduce modeling demands on the designer.

Issue4: The general focus is on surface warships, although the need to approach could be applicable to preliminary design of any other type of ship and of other enclosed environments where complex personnel operations take place (The integration of personal movement method could be applicable to other limited type of ship).

Summary and Conclusions

The ship arrangements methodologies has been steadily increasing during the past 30 years. navies around the world are interested in performing analyses that rely on system layouts during preliminary design in order to build confidence in the ultimate feasibility of candidate designs. The coupling between requirements and ship size, cost, and performance is due in large part to the arrangement of the vessel. The earliest stages of ship design is considered the most crucial design stages in terms of the consequences of any decision taken. Flexibility of early stages design, as well as that of a design process in general, is the characteristic that allows design solutions to be readily adapted to changing conditions and meet a ranged set of design requirements. Developing the three-dimensional compartment and component arrangements for these ships is a challenging and time-consuming task partially because each layout includes hundreds or thousands of elements with interconnecting and sometimes conflicting relationships. Deep understanding of the relationships and circulation among ship spaces with keep in mind the previous aspects, in the same time, developing the design methodologies and creating new approaches will rabidly generate a stable arrangements that reduce time it is then cost.

Keywords: vehicle collision avoidance, obstacle, BP artificial neural network, driving path planning, simulation

Abstract: This article establish a model to give a detailed analysis of road vehicle collision avoidance systems according to the angle between vehicle and obstacle, and raise a vehicle collision avoidance detecting mechanism based on location mapping and distance detecting; furthermore, The authors combined this mechanism and BP artificial neural network to establish a new vehicle collision avoidance systems which is based on the collaboration between precise distance angle model and BP artificial neural network. We called this mechanism as BP artificial neural network vehicle collision avoidance model, the abbreviation is BP collision model. The convergence simulation of such model present that this model can resolve problem of collision avoidance and plan driving Path very well.

Introduction

The purpose of vehicle collision avoidance systems is to alarm the driver at dangerous moment, or directly control the car to avoid collision. ACC,adaptive cruise control, system is a kind of Collision avoidance function control system. however, this system need to consider lots of complex factors, such as the basic characteristics of the vehicle location and speed, and the traffic road congestion level, as well as the road situation (e.g. directly road, T-junction, Crossroads).those complex factors bring lots of difficulty to the construction of collision model by using Classical mathematical method, and cause ACC model only can be used on simple road situation. recently, many researcher try to use fuzzy mathematics , artificial neural network ,or together of them to establish predict model to analyse collision problem. they have achieved some results, but there are still some difficulty needed to be resolved, e.g although fuzzy mathematics is better able to adapt to human perception and behavior as well as some of the difficult to accurately quantify the working conditions quantified using fuzzy approach, however, due to limitations of its own characteristics, it is difficult to characterize better on complex road situation. Although artificial neural network model has good self-learning features to suit the driver driving habits, but such mode required some learning and training must be carried out in advance, and there is relatively slow convergence problems in this model, additionally, traditional artificial neural network model is also difficult to characterize better on complex road situation same with fuzzy mathematics model.

In this paper, we try to raise a new collision avoidance systems which combine traditional accurately mathematical model and BP artificial neural network. New model combined two traditional models each other, they learn from each other; new model has a self-adaptive inferential control system in terms of artificial neural networks, and train neural network to achieve a better convergence effect by using additional momentum term learning algorithm, the success of the convergence of the neural network also confirmed the proposed model is reasonable and reliability.

Model Construction

Accurately Mathematical Model Based On Road Obstacle

The main factors that affect driving action include the vehicle speed, nearby vehicle speed, as well as the distance with nearby vehicles as so on. However, in complex cases, the environment traffic of local vehicle, road width, road sections are all able to determine the degree of risk.

Firstly, let's describe the environment of vehicles running, as we see from figure1, the vehicle is running on the road, we assume the scanning angle scope of vehicle is $[-\sigma,\sigma]$, negative number represent vehicle turn to left. We assume the scanning angle of vehicle is 2σ, and 2σ is divided into n blocks, we denote the angle of block i as θ_i ($\theta_1 = 0$), Each direction obstacle distance which is measured by using microwave radar or machine vision approach is l_i.

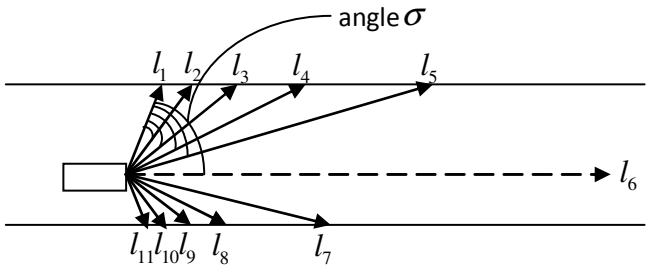

Fig. 1 Schematic diagram of environment of vehicles running

This method uses multiple parameters to characterize the road situation, this model take lots of factors into consideration, such as the distance to nearby vehicle and nearby obstacle, the location of local vehicle, as well as the distance to road marginal. Those factors all can be presented in $\vec{l} = (l_1, l_2, ..., l_n)$, the precise degree is decided by n.

On the basis of road model, we analyse the vehicle collision avoidance procedure

Let's assume the speed of local vehicle is $v_c (\geq 0)$, brake acceleration is a_c, the minimum safety distance is d_s which is the minimum distance between local vehicle and obstacle keeping for avoid collision. Driver reaction time is T_r. Subsequently, we construct a accurately model with output of turning angle $\varphi_r \in [-\sigma,\sigma]$ and acceleration a_r.

Firstly, we try to find a safety zones, the every safety distance of every direction should be more than a safety threshold; this threshold should be decided by vehicle speed v_c and reaction time T_r.

Make safety running distance as $c_s = \frac{v_c^2}{2a_c} + v_c T_r$ (formula 1)

Make safety running angle as $\theta_s = \frac{d_s}{c_s}$ (formula 2)

The sense of c_s is minimum safety distance between local vehicle and obstacle (different with d_s), based on this model , we get a conclusion that vehicle must find a forwarding angle which there is a accessibility region with radius equal or bigger than c_s, at the same time d_s should be out of the scope of this region(e.g figure 2). To simplify the calculations, we make fan arc length equal to d_s ,so we got a safety running angle θ_s.

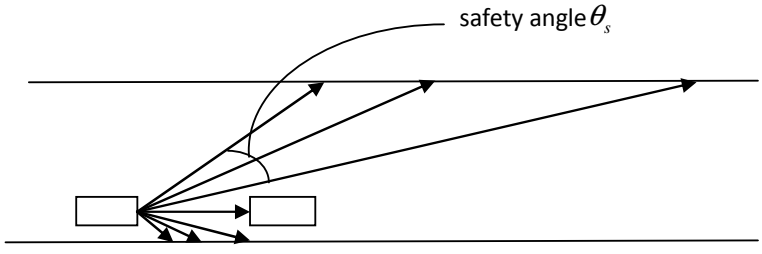

Fig. 2 Schematic diagram of safety zones

With this safety running angle θ_s ,the task of vehicle collision avoidance systems will become to find a safety running angle region θ_s in the scope of the scanning angle $[-\sigma,\sigma]$, the all l_i of this safety running angle region should ensure equal or bigger than c_s ,the formula is $l_i \geq c_s$, then we translate this region to $\varphi_r \in [-\sigma,\sigma]$ as a output;

The algorithm of finding safety running angle region is described as below:

Step1: set a initial value $k=\frac{n}{2}+1$ (the index of the initial angle block), $n_s=\frac{\theta_s n}{2\sigma}$ （the block amount of safety running angle region ）, $\mu=\frac{2\sigma}{n}$ （the angle scope of every block）, $i=j=k$, the binary function of this model is $f(x,y)=\min\{l_{x+j}\mid\ 0\leq|j|\leq y\}$

Step2: if $i\in[1,n]$ and $f(i,\frac{n_s}{2})\geq c_s$ then $\varphi_r=i\mu$ go to Step6,otherwise to Step3;

Step3:if $j\in[1,n]$ and $f(j,\frac{n_s}{2})\geq c_s$ then $\varphi_r=j\mu$ go to Step6,otherwise to Step4;

Step4:if $i\notin(1,n)$ and $j\notin(1,n)$ then go to Step5,otherwise if $i\in(1,n)$,then $i=i+1$, if $j\in(1,n)$ then $j=j-1$, go to Step2.

Step5:can not find safety running angle region, output $a_r=a_c$.

Step6:find a safety running angle region, output φ_r value.

The essence of the above algorithm is to looking for a safe running area in the area closest current direction.

Bp Artificial Neural Network Model Based On Self-Learn Mode

Above collision avoidance model has real-time, accurate calculation and other characteristics, but does not have the learning function and adapt to the driver's characteristics; but BP artificial neural network has good classification, prediction, reasoning characteristics for input mode. Then, we will establish a BP artificial neural network model to analyse collision avoidance problem.

We take the vector of 2.1 $\vec{l}=(l_1,l_2,.....,l_n)$ as input parameters of BP artificial neural network, we make turning angle φ as output parameters by using turning angle mapping algorithm , $\vec{y}=(y_1,y_2,.....,y_n)$ （$y_i\in\{0,1\}\ \&\sum_{i=1}^{n}y_i=1$） , the BP artificial neural network model is as below figure 3;

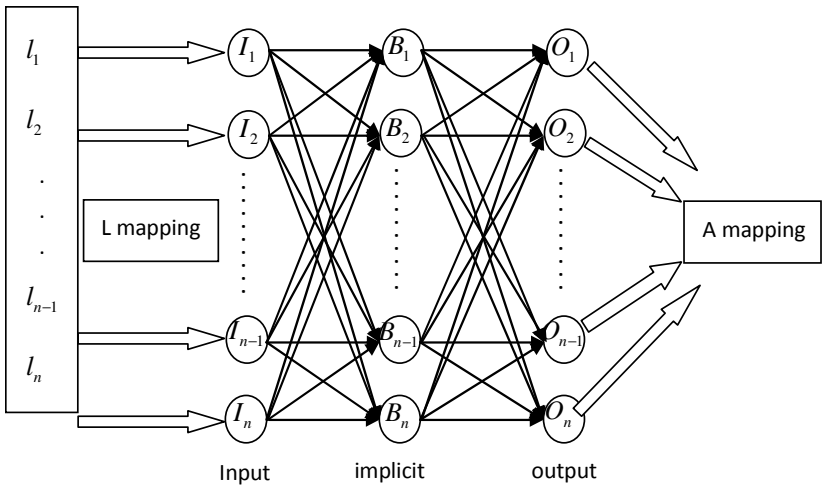

Fig. 3 The BP artificial neural network model

The input parameters is $\vec{I}=(I_1,I_2,.....,I_n)$,connection weight matrix is W^i （$i=1,2$） ,output parameters is $\vec{O}=(O_1,O_2,.....,O_n)$, implicit layer is $\vec{B}=(B_1,B_2,.....,B_n)$, the threshold between implicit layer and output layer is $\vec{\gamma^i}=(\gamma_1^i,\gamma_2^i,.....,\gamma_n^i)$ ($i=1,2$),we set Sigmoid as transfer function $y=f(x)=\frac{1}{1+e^{-x}}$.

The calculate procedure for input parameters is below:

Input layer: finish vector location mapping and normalized processing, the node value of this layer is $I_i=\frac{l_i}{\sum_{j=1}^{n}l_j}$.

Implicit layer and out layer: the input of every node $s_j=\sum_{i=1}^{n}X_iW_{ij}^k-\gamma_j^k$,the output of every node $Y_j=f(s_j)$.

A Mapping: this mechanism complete the mapping between turning angle and output parameters, And vice versa; because only one turning angle value is not good to the calculation of BP artificial neural network, so we construct two function between turning angle φ and output parameters $\vec{O}=(O_1,O_2,.....,O_n)$, the functions is below:

$\varphi(O)=\mu\prod_{i=1}^{n}iO_i-\sigma$, $O_i(\varphi)=\begin{cases}1 & (i=\left[\frac{(\varphi+\sigma)}{\mu}\right])\\ 0 & (else)\end{cases}$, （the define of μ and σ refer to 2.1）

The Combination And Collaboration Between Two Model

BP artificial neural network can better adapt the human behavior, the driving characteristics of the human , the training and learning of the neural network based on the driving characteristics of the human is more helpful for the neural network to avoid collision in the same driving conditions, the characteristics that artificial neural network present similar behavior according to a similar input parameter achieve the good approach to purpose of collision avoidance.but the problem is we must provide training sample in advance, so the sample can't cover all traffic and road scenarios, then in loss scenario, BP artificial neural network will not output reasonable reaction;

Due to above question, we should provide a low level 'intelligent' for BP artificial neural network, to improve the behavior of our model, so that the program can output a basic reaction for any scenario.

As a compensation, the accurately mathematical model based on road obstacle of 2.1 combine with BP artificial neural network of 2.2, firstly, the filter or alarm mechanism judge the dangerous status , and reload the environment parameters $\vec{l} = (l_1, l_2, ..., l_n)$ into collaboration system; secondly, BP artificial neural network model calculate out the turning angle of collision avoiding; thirdly, the verification mechanism will verify whether the output of BP collision model is correctly or not, the verification is based on the comparison with accurately mathematical model; if BP artificial neural network model result is not correct, the correct result of accurately mathematical model will feed back to BP artificial neural network, BP artificial neural network will learn the correct result, and adjust the network parameter; the whole BP collision model is described as figure4;

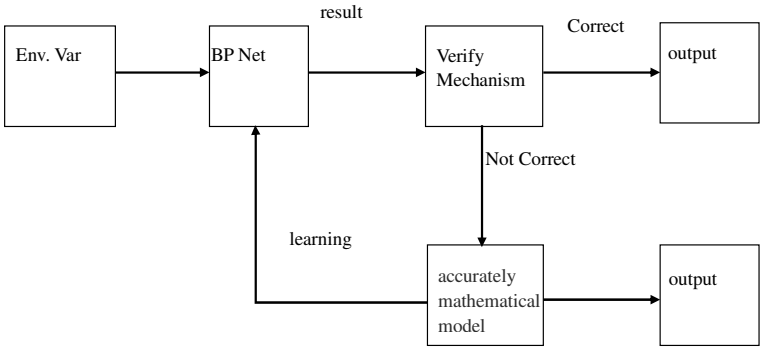

Fig. 4 The learning model for the BP artificial neural network

The verification mechanism is mainly to calculate whether the vehicle can avoid collision in current speed and turning angle, so the verification only need to calculate whether result φ comply the formula $f(i, n_s) \geq c_s$ (refer 2.1).

While the BP artificial neural network has no any training and learning (initial situation, random weight value), if above collaboration system is directly used to collision avoiding control, at the beginning, the result of BP artificial neural network is always wrong; after BP artificial neural network learned lots of traffic scenario and know what is correct output for this scenario, then BP artificial neural network will response all similar scenario correctly, the accuracy of BP artificial neural network will become more and more higher. Further, the reaction of driver for the emergency case should be as the main source of neural network learning, otherwise the collaboration system degenerates to accurately mathematical model; on the contrary, if BP artificial neural network mainly depend on learning driving reaction, and ignore the result of accurately mathematical model, then whole BP collision model will become a pure artificial neural network.

Model Simulation (Convergence Test)

Firstly, we set the connection weight value of BP artificial neural network as a random value, then we collect some traffic environment parameter to simulate the procedure of figure4, and test the system convergence of such artificial neural network. The learning algorithm of BP artificial neural network is standard error correction method, also collaborate with adaptive learning rate adjustment algorithm.

Base on model one, We construct some learning sample as below table 1 to test the system convergence.

TABLE 1 LEARNING SAMPLE BASE ON MODEL ONE

Learning algorithm uses the steepest descent learning algorithm, collaborate with momentum $W(n+1)=\alpha\frac{\partial E}{\partial W}+\beta W(n)$ to train BP artificial neural network, convergence test result is below.

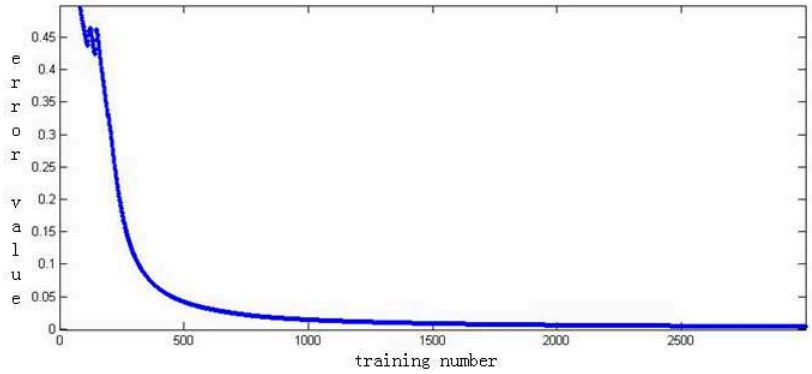

Fig. 5 Module simulation

Conclusion

This article is mainly from accurate detect obstacle perspective, to establish a collision avoiding algorithm which combine BP artificial neural network and accurately mathematical model, and then specify the specific calculation step and procedure. The convergence test of BP collision model present a good collaboration effect, the simulation result also prove that this model is reasonable and reliable.

The next important research point is about the collaboration system adaptive with neural network model, and the problem of error concussion and slow convergence of BP artificial neural network. So a successful convergence decide the whole effect of BP collision system, we plan to improve the initial value of BP network and introduce a Simulated annealing algorithm to collaborate with BP network, those further job will improve the performance of BP artificial neural network more deeply.

Keywords: quantitative risk assessment, PH value, disqualified textiles

Abstract. The assessment of potential risks posed by PH value in clothing to consumers is of increasing concern worldwide. If the PH value is too high, it is harmful to skin. Some papers focus on hazard assessment and exposure assessment, using quantitative and semi-quantitative method, rather than assessment for the factors related to the PH value. In order to perform early-warning research and risk management, the quantitative risk assessment is used in this paper to analyze the imported textile testing data and find the factors related to the PH value. The data mining technique and K-means algorithm is the core of the method. It can be concluded that the disqualified textiles have relations with main fiber components and fabric color. Then cluster the data by K-means algorithm for every factor, define the different class as related danger level, respectively severe, moderate, light.

Introduction

In recent years, the demand for imported textile products has increased prominently. But there are some security issues in these products. According to statistics of the General Administration of Quality Supervision [1], only in 2011, the failure rate is as high as 10.17 percent. Although these disqualified textiles may not threaten life directly as disqualified food, they have a great harm to health and can't be discounted [2].For example, if PH value of clothing is too high, it will stimulate the skin, and even lead to skin infections [3]. Therefore, risk management[4] is used to find the factors related to the PH value and take some measures to reduce risk. The European chemicals agency performs hazard and exposure assessment [5]. However these assessments define the dangerousness rather than the related factors for risk management. Usually, the quantitative risk assessment uses the Bayesian algorithm [6]. It calculates the probability of the factors, add or multiply the value to get the probability under certain condition [7], but it is not good at internal analysis. Some quantitative risk assessment uses Rough sets based algorithm [8], classifying the data according to the constructed function. But this algorithm is not well in non-numerical analysis. Some data in this paper is not numerical. So the paper uses the K-Means algorithm to classify the factors into

different levels [9] according to their percentage in the same attribute. By this way, the related attributes for risk management and the most relevant factors can be found to perform the early warning research and risk management.

Methodology

Data Collection and Sorting

SPSS Clementine [10] is data mining software and can import SPSS files, SAS files, Excel and so on. In order to input the data and establish the model conveniently, the data in the imported textiles test report (provided by the Shanghai Entry-Exit Inspection and Quarantine Bureau) is processed to Excel format. Excel is convenient to convert the data after collecting them. The layout is shown in Table1.

TABLE 1 DATA SAMPLE

Register Number	PH value	Main components	Color
911852**	6.4	Wool	Black
911852**	6.5	Mulberry Silk	Green

Cluster Analysis

The data collection is divided into many classes composed by many similar objects. The process is called clustering. These objects in the same class are similar to each other, different from other classes'. Cluster analysis originates from taxonomy, but it is not classification. The difference between them is that the type of required classes in clustering is unknown.

K-means clustering algorithm [11] is commonly used and also used in this paper to calculate the K-means node. It is a typical distance-based clustering algorithm, using distance as the similarity evaluation indicator. It means that the shorter the distance of the two objects is, the greater the similarity is. We herein show the definition of the K-means algorithm as follows:

(1) Select a set of K randomly from the collection, number of which is N, as initial cluster centers;

(2) Measure the distance between each residual data and each centroid. Classify the residual data to the nearest centroid's class;

(3) Recalculate the centroid of each class;

(4) Iterate 2-3 steps until the new centroid equal to the original centroid or the distance between them is less than the specified threshold, the algorithm terminates.

Data Analysis

As for PH value issue, this paper will analyze its relationship with fiber components, and fabric color.

PH Value and Main Fiber Components

Excel spreadsheet is imported as source node. Then select the node and pick out the data that the PH value is not within the standard range. The structure of model is shown in Fig. 1 and the percentage distribution graph of main fiber components is shown in Table 2.

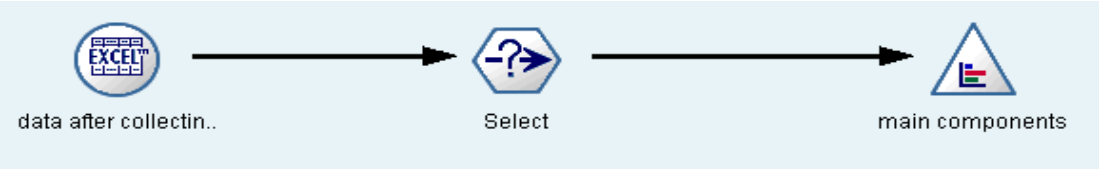

Fig. 1 Disqualified Textiles and Main Fiber Components Model

TABLE 2 PERCENTAGE DISTRIBUTION OF MAIN FIBER COMPONENTS

Number	Main fiber components	Percentage
1	Polyester	3.3
2	Cotton	56.67
3	Mulberry silk	4.17
4	Rabbit hair	0.83
5	Linen	3.33
6	Wool	22.5
7	Cashmere	7.5
8	Rayon	1.67
	Total	100

It is obvious to be seen from Table 2 that the percentage of cotton textiles is highest, accounting for 56.67%. It is because that the dye process for cotton must be in the alkaline environment [12]. After dyeing, acid should be used to neutralize the alkali, so the PH value can be within the standard range. If acid is not enough, the PH value will be high. So it is necessary to classify the data to monitor the safety of the products. K-means algorithm is used .Set K = 3, the structure of model is shown in Fig. 2 and the results are shown in Table 3.

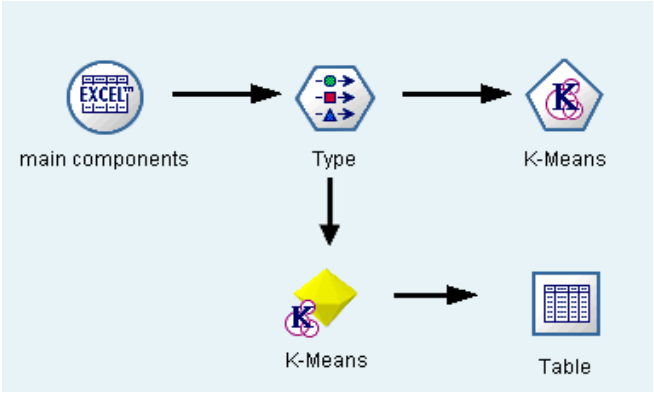

Fig. 2 Main fiber components cluster analysis model

TABLE 3 CLUSTER ANALYSIS RESULTS OF MAIN FIBER COMPONENTS IN DISQUALIFIED TEXTILES

Number	Main components	Percentage	Class	K-means
1	Polyester	3.3	Class 1	0.003
2	Cotton	56.67	Class 2	0
3	Mulberry silk	4.17	Class 1	0.013
4	Rabbit hair	0.83	Class 1	0.047
5	Linen	3.33	Class 1	0.002
6	Wool	22.5	Class 3	0
7	Cashmere	7.5	Class 1	0.072
8	Rayon	1.67	Class 1	0.032

It can be concluded from Table 3 that class 2, cotton textiles, has highest proportion, classified as severe warning. The class 3, wool textiles, is moderate warning. The class 1, other kinds of textiles, is light warning. So textiles safety supervision department should focus on textiles belonging to the severe, moderate warning and make great efforts in test, especially for cotton, wool textiles.

PH Value and Fabric Color

PH value is different for different color textiles in the dyeing process. Just as main fiber component, the percentage distribution graph of fabric color is shown in Table 4:

TABLE 4 PERCENTAGE DISTRIBUTION OF COLOR IN DISQUALIFIED TEXTILES

Number	Color	Percentage
1	White	12.05
2	Navy blue	10.84
3	Black	15.66
4	Red	13.25
5	Yellow	8.43
6	Grey	15.66
7	Blue	8.43
8	Green	7.23
9	Purple	1.20
10	Brown	7.23
	Total	100

Judging from the Table 4, the number of white and grey is large, accounting for 37.71%, although the percentage of the disqualified white and grey textiles in the total textiles is not high. In general, these disqualified problems occur to the dark color textiles. But for PH value, it is potential for the light color textiles to be disqualified.

Cluster the data in Table 4 by K-means. The results are shown in Table 5.

TABLE 5 CLUSTER ANALYSIS RESULTS OF COLOR IN DISQUALIFIED TEXTILES

Number	Color	Percentage	Class	K-means
1	White	12.05	Class 1	0.1
2	Navy blue	10.84	Class1	0.183
3	Black	15.66	Class1	0.15
4	Red	13.25	Class1	0.017
5	Yellow	8.43	Class3	0.041
6	Grey	15.66	Class1	0.15
7	Blue	8.43	Class3	0.041
8	Green	7.23	Class3	0.041
9	Purple	1.20	Class2	0
10	Brown	7.23	Class3	0.041

The class 1 in the above table, namely white, navy blue, black, red and brown, has higher percentage, is classified as serve warning. Yellow, blue, green and brown, is moderate warning. Purple, class1, is light warning. The departments should take reasonable arrangements of detection in textiles according to the danger level during safety supervision.

Conclusion

In this paper, the data mining technique is used to analyze the imported textile testing data to find the factors related to the disqualified textiles. It can be concluded that disqualified textiles have relations with main fiber components, fabric color. Cluster the data in the same attribute by K-means algorithm and define the different danger level, respectively severe warning, moderate warning and light warning.

Discussions of Resource Utilization of Coal Gangue

Huamin Li

Planning and Design Research Institute of Coal Industry, Beijing, 100120, China

Keywords: coal gangue, utilization, electricity generation, chemical utilization, building materials

Abstract: The ways of using coal gangue in electricity generation, chemical utilization and building-material production are introduced and national coal gangue utilization status and development trend is analyzed in this paper. Pointing out the main problems in present utilization of coal gangues, suggestions on coal gangue resource utilization are given that provide reference for eliminating coal gangue pollution, enhancing environmental protection and saving up energy.

Foreword

Coal gangue is a kind of rock that comes with coal during coal forming. It is the solid waste in the process of coal producing and processing，and was regarded as “industrial waste” and “public nuisance”. China is one of the main countries that produce and consume coal; coal gangue takes up the most part of industrial solid waste. To now, there be more than 5000Mt of coal gangues in China, and coal gangues are increasing by the speed of more than 100Mt per year. There are more than 1500 coal gangue maintains，taking of more than 100km^2 lands. Those coal gangues not only increased the contradiction between human and land, but also changed the structure and function of the land, and damaged the plant ecosystems. Coal gangues will spontaneously combust when exposing to the sun, and release harmful gases, polluting the air, causing fire disaster, subsidence damage and explosion. Waste dumps also cause soil pollution. The harmful elements in coal gangues will get into water and soil with the rain, influencing the quality of water and soil.

According to coal gangue’s different calorific value and chemical component, it can be used in many resource assimilation ways, including the use of the coal gangues’ heat (ashes can be reused), producing building materials, recycling useful mineral, making chemical products etc.

The approaches and status of resource utilization

The heat usage of the coal gangues

The heat usages of coal gangues include fuel utilization and electricity generation. Fuel utilization requires relatively high heat value, only a few coal gangues can meet this criterion. However, most of the coal gangues can be used to generate electricity. In our country heat value of the coal gangues are mostly under 6.3MJ/kg，in which 3.3~6.3MJ/kg, 1.3~3.3MJ/kg and lower than 1.3MJ/kg each takes up 30%. The coal gangues, which heat value is higher than 6.3MJ/k, take up about 10%. Those coal gangues that heat productivity is higher than 7.5MJ/kg can be used as the fuels of boiling furnace and circulating fluidized bed boiler directly. Slime can be added into coal gangues that produce heat in the range of 5.02～7.5MJ/kg，and used this mixture for generating of electricity. After mixed with coal slime and washing middlings can be used as circulating fluidized bed electric generation.

In our country, coal gangue electric generation has a twenty-year history. In early times, boiling stove burning technology is the main method, which causes problems of serious pollution and low combustion efficiency. In the 1990s, the circulating fluidized bed combustion technology began to

employ. This small-sized industry gradually changed into 135MW, 300M and 600MW sets，making the utilization of the coal gangue, along with the slime electric generation a world-class technology. Up to now, national utilization of coal gangue electricity plant's total installation scale has reached 26000MW. Generating electricity by coal gangues has become a vital part of large-scale use of coal gangues. This can not only save up good-quality coals, reducing the coal and electricity shortage, but also be recycled as building materials in some electric plants, realizing environmental friendly.

The building materials utilization of coal gangues

Another way of large-scale use of coal gangue is to produce building materials, including coal gangue brick-making, cement and lightweight aggregates.

Coal gangue brick making: Coal gangue bricks include sintered bricks and pastes. Sintered bricks are mainly made from coal gangue, taking up 80% weight of the ingot, and some are made just by coal gangues. In the sintering process, by using coal gangue's own calorific value, using as less coal as possible, can save up soil taken from farmlands and save up energy. Coal gangues using for pastes require a thermal value between 2.10 and 3.30MJ/kg. Coal gangue pastes are usually made from burned coal gangues (such as Spontaneous combustion coal gangues) mixed with certain percentage of cement, lime (or limestone), enhancers, and water, through the process of crushing, batching, mixing high-pressure molding and curing processes, without the use of high-temperature sintering. Nowadays, there are thousands enterprises devote coal gangue brickmaking, annually using 16Mt of coal gangues, annually save up farmlands about 7km^2，and save up coals about 0.6Mt per year.

Producing cement by coal gangues: Mainly used as cement's adjuvant. In some areas that lack of clay silicon and aluminum raw materials, there is a long history for using coal gangue instead of some part of silicon and aluminum raw materials with mature production technology, but due to unstableness of the presence of components and high application cost and other factors, it is now commonly used at present. Coal gangue used as cement admixture is affected by factors such as loss on ignition, therefore in less use. Utilization of coal gangues as aggregate has stableness problems, is also not widely used.

Producing lightweight aggregates by coal gangues: 40 percent of China's stockpiling of coal gangue is suitable for firing lightweight aggregate. About 10% of the burned coal gangues after crushing and selecting can make directly into lightweight aggregates. Carbonaceous shale and coal washing waste rocks are usually used for firing lightweight aggregates. Coal gangues that contain 13% or less carbon are best suited for this process.

Extract Usable Components and Make Chemical Products

Coal gangues that contains high portion of Aluminum can be used to extract Al_2O_3, produce Aluminum chloride and crystalline aluminum chloride. Coal gangues contain high portion of Silicon can be used to produce Sodium silicate, alum and Sodium metasilicatenonahydrate. Coal gangues can also be used to produce calcined kaolin. Up to now, the industrial utilization of coal gangues is still at experimental stage. However, there are projects on extract Al_2O_3 from fly-ash has industrial demonstration running. Also, there are also progresses on researches of extracting germanium, gallium, vanadium and other useful components from coal gangues.

The Main Problems in Coal gangue Utilization

Low Utilization Rate of Coal gangue Resource

Up to now, the coal gangues and other forms of solid waste, which used for power generation as a low calorific value fuel and the production of building materials, are about 300Mt in China. In 2010, 770Mt coal gangue is discharged national wide; electricity generating and building material

utility is less than 40%. To the 180Mt coal gangues that can be used as electric generation, the efficiency is only about 30%. This is far from the requirement of utilize coal gangues properly, causing the amount of stored up coal gangues to increase. As we can see, there is a huge gap between newly produced coal gangue and the limited amount of coal gangue of present coal gangue utilization takes up. The problems of resource wasting and environmental issues are severe.

According to prediction, the year 2015, 2020 our country's coal production will reach about 3800Mt, 4200Mt. The production of coal gangue will reach 950Mt, 1050Mt，among which the low-calorific level coal gangue that can be used to generate electricity will reach 620Mt, 680Mt. Therefore, properly dealing with and utilizing coal gangue is under great pressure. The coal gangue utilization can be strengthened.

Present coal gangue Integrated Utilization Do Not Deliver the Circular Economy Mode

Due to historical reasons, present coal gangue integrated utilization electricity plant did not consider including mines' circular economic logistics chain when established, and locate coal gangue integrated utilization electric plants as mines' plants that provide their own electric. As the development of mines and coal-energy, present coal gangue electricity generation enterprises cannot satisfy the need in unit efficiency, level of environmental protection, economy aspect, coal gangue assimilative capacity and contribution to circular economy to the mines. By improving technology, operational management level, industrial level and scientifically establish new project to turn the tide is the main task in present.

Coal gangue is Located at the Lower End in the Utilization Value Chain

Coal gangue is widely used in electricity generation and brickmaking. However, due to low added value, most of them are at the end of the value chain. Especially in the coal gangue building materials aspect, which mainly used in wall materials, have low prices therefore most industries are worse off. Reuse of useful component in coal gangues and make high added value is still in the research and demonstration process, not ready for implement. Therefore, the efficient way to search for high-level utilization of coal gangue is in need.

Lack of Research on Coal gangue Composition and Basic Feature

Up to now, the lack of research on coal gangue composition and basic feature is obvious, especially on beneficial component, acidity, heavy metal pollution and other problems are vital. The amount and distribution of acidic spontaneous combustion coal gangues is not clear, which affects the development of environmental protection technology and high-level utilization of coal gangues.

Suggestions

Value Planning and Developing Circular Economy

Value the planning of coal gangue utilization as well as the planning of coal and electricity and other related aspect. Consider coal gangue utilization distribution as a whole, according to the conception of circular economy and local coal industry distribution. In area with sufficient coal gangue resources, plan coal gangue utilization program according to local coal gangue quality and characteristics to improve the utilization rate.

Speed up the Pace of Industry, Academia, and Research Joint

Set up research group to develop coal gangue utilization important project and key-technology. Focus on the vital problems such as big set of coal gangue electricity generation, producing Alumina and Silicon aluminum alloy, organize specific research and establish national research center to perfect the technology support system, speed up the pace of industry, academia, and research joint to provide guaranteed coal gangue utilization and cutting-edge scientific development.

Doing Well On Basic Data Research and Evaluation

Do well on coal gangue on the basic data researches and evaluation on coal gangue's distribution, amount, type, and specialty. Establish database, method base, decision base of coal gangue utilization can provide detailed and reliable information for efficiently develop and utilize the coal gangue.

Supporting Coal gangue Resource Utilization Project on Environmental Capability Aspect

Tons of coal gangue production has brought severe environmental pollution to local areas. Coal gangues emit lots of pollutants, but show no quantitative reflection. After the resource utilization of coal gangue, pollutants are organized emitted. The amount of pollutant emission is in fact reduced, but the net increase amount in accounting basis is raised. Therefore suggest the nation to consider resource output regions' actual situation, and support coal gangue resource utilization on environmental capability aspect， improving integrated environmental benefits.

Research on Modes of Recycling and Remanufacturing with Considering the Carbon Footprint

Yue Jiang [1,a *]

[1] Department of Management Science, School of Management, Xiamen University, Xiamen 361005
[a]jiangyuehxg@126.com

Key words: carbon tax, mode of recycling and remanufacturing, remanufacture

Abstract: Three modes of recycling and remanufacturing are discussed when the carbon tax is imposed, the impact of carbon emissions on the mode of recycling and remanufacturing is further analyzed. The results show that the optimal price and sales of the new product and remanufactured product in the second stage are relevant with the carbon emissions in their manufacturing and selling process, not relevant with the carbon emissions in their recycling process. OEM will be more inclined to remanufacture themselves with the increasing environment awareness of consumers.

Introduction

With the introduction of relevant laws and policies, the increasing of customer environment awareness, and the business opportunities arising in the remanufacturing and recycling process, more and more companies begin to get involved in the recovery and remanufacturing activities. The value of the product has not been completely consumed when it is in the use of termination, there is also surplus value can be reused, so recycling and remanufacturing in more and more important, on one hand, it can improve the efficiency of resource, on the other hand, it can reduce the pollution, so how to recycle and remanufacture is a problem that the government and the enterprise must consider. During the past decades, society at large has awakened to the issue of climate change. Climate changing and global warming are higher on the minds of consumers around the world than ever before. IPCC 2009 indicated that the carbon emissions are the main factor, a carbon tax on enterprises will be imposed in the future according to the report about the design about carbon tax in China. So the cost of carbon is a factor that must be considered in choosing the mode of recycling and remanufacturing. The paper is organized as follows: After this introductory section, the relevant literature is reviewed. Section 3 is about the modes of recycling and remanufacturing with considering the carbon footprint. The analysis of three modes of recycling and remanufacturing is described in Section 4. Our conclusions are given in the final section.

Literature Review

Our paper is positioned among two main streams of literature. The first is related to the carbon emissions, the second relates to recycling and remanufacturing. Regarding the first stream, Benjaafar(2009) is the first who consider carbon emissions in supply chain, he establishes a model of carbon emission allowances, model of carbon tax allowances and model of carbon trading. HonLoongLam(2009) designs a supply chain network considering carbon footprint, the performance of supply chain about the carbon is aslo discussed in this paper. FlavioManenti(2010) constructs a index system about environmental development and carbon footprint. Xianyuan(2012) Chang builds a production decision model using the method of decision optimization considering both the cost and the carbon emissions. For the second stream, Yi Wang(2009) studies the impact on manufacturers and distributors with the law system of manufacturer responsibility and distributor responsibility. Savaskan(2007) and Shunli Xue(2007) consider optimal decision in three recycling channels, which

are manufacturer responsible for recycling, distributor responsible for recycling and the third party responsible for recycling. Webster (2007) researched the impact on recycling rate of government compensation. In summary, existing papers have made some achievements in Carbon footprint aspect and recycling and remanufacturing aspect, but only recovery cost is considered in recycling and remanufacturing, the cost of carbon emission is not considered, so this paper introduces the cost of carbon emissions into the recycling and remanufacturing process, the modes of recycling and remanufacturing are analyzed with considering carbon emission using a combination methods of qualitative and quantitative.

Model

Our paper considers a two-stage game model which only an original equipment manufacturer (OEM) and a remanufacturer are considered when carbon tax is imposed by government according to the emissions of carbon. In the first stage only new products are sold, in the second stage, there is competition between new product and remanufactured product, and the supply of the remanufactured products are decided by the first stage.

The First Stage

We assume that the standardization of market size is 1, the evaluation of the customer about the product is uniform distribution on [0,1] ,and we also assume that cumulative distribution function is F(v)=v, the willingness to pay of the customer is decided by the quality of the product, if the willingness of the new product is v, then the willingness of the remanufactured product is βv，$0 \le \beta \le 1$。 p_1 is the price of the new product in the first stage, q_1 is the demand of the new product in the first stage, in this time there ares only new product in the market, so when the utility of customer $v - p_1 \ge 0$, then consumers will purchase products, so the demand of the new product in the first stage is $q_1 = \int_{p_1}^{1} dF(v) = 1 - P_1$ (1). The raw materials and manufacturing process of each product are the same as each other, so the carbon emissions of each product in the manufacturing process are the same as each other, we assume that is Ω_n. Due to the locations of customers, sales channels are different, so the carbon emissions of product are different, but in order to simplify the model, we assume that the average carbon emissions of the product in selling process is Ω_s, we also assume the tax of the carbon is t yuan each tone, c_n is unit production cost of new product, then profit function of OEM in the first stage is

$$\Pi_{OEM}^{1} = (p_1 - c_n - \Omega_n t - \Omega_s t) q_1 \quad (2)$$

According to equation (1) and (2), We can get that $\Pi_{OEM}^{1} = (P_1 - c_n - \Omega_n t - \Omega_s t)(1 - P_1)$ In order to maximize the profit, we can get

$$p_1^* = \frac{1}{2} + \frac{c_n}{2} + \frac{\Omega_n t}{2} + \frac{\Omega_s t}{2}, \quad q_1^* = \frac{1}{2} - \frac{c_n}{2} - \frac{\Omega_n t}{2} - \frac{\Omega_s t}{2} \quad \Pi_{OEM}^{1*} = \frac{1}{4} - \frac{1}{4}(c_n + \Omega_n t + \Omega_s t)^2 \quad (3)$$

The Second Stage

In the second stage, there are both new product and remanufactured product in the market, consumers buy new products or remanufactured product is mainly based on self-selection, which is determined by comparing the utility surplus, utility surplus is equal to utility minus price. p_n is the price of new product in the second stage, q_n is the demand of new product in the second stage, p_r is the price of the remanufactured product in the second stage, q_r is the demand of the remanufactured in the second stage. In the second stage the customers will buy new product if the utility of the new product is greater than zero and the utility of new product is greater than the utility of remanufactured product, that is $v - p_n \ge 0$ and $v - p_n \ge \beta v - p_r$, so we can get $\begin{cases} v \ge p_n \\ v \ge \frac{p_n - p_r}{1 - \beta} \end{cases}$ (4)

The customers will buy the remanufactured product if utility of the remanufactured product is greater than zero and the utility of the remanufactured product is greater than then new product, that is $\beta v - p_r \geq 0$ and $\beta v - p_r > v - p_n$, so we can get $\begin{cases} v \geq \frac{p_r}{\beta} \\ v < \frac{p_n - p_r}{1-\beta} \end{cases}$ (5).When $p_r \geq \beta p_n$, only inequalities(4) are solvable, at this time, only new product in needed; $p_r \leq p_n - (1-\beta)$ time, only inequalities(5) are solvable, at this time, only remanufactured product is needed; $p_n - (1-\beta) < p_r < \beta p_n$ is considered in our paper, at this time the solution of (4) is $\frac{p_n - p_r}{1-\beta} < \beta < 1$， the solution of (5) is $\frac{p_r}{\beta} < v < \frac{p_n - p_r}{1-\beta}$, both new product and remanufactured product are needed in the market, the demands of new product and remanufactured product are $q_n = \int_{\frac{p_n - p_r}{1-\beta}}^{1} dF(v) = 1 - \frac{p_n - p_r}{1-\beta}$

$q_r = \int_{\frac{p_r}{\beta}}^{\frac{p_n - p_r}{1-\beta}} dF(v) = \frac{p_n - p_r}{1-\beta} - \frac{p_r}{\beta}$ (6). So we can get $p_n = 1 - q_n - \beta q_r$ $p_r = \beta - \beta q_r - \beta q_n$ (7)

Recycle and Remanufacture

According to recycling rules in our nations, in the second stage, OEM must recycle their waste products which are generated in the first stage, if individual responsibility for recycling is used, OEM can control waste products completely. OEM can choose remanufacturing and also choose not remanufacturing, if OEM chooses remanufacturing, then there is no remanufacturer in the second stage, OEM can control the new product and manufactured product completely, this is a monopoly model of new product and remanufactured product, which is denoted as mode A. If OEM do not want to remanufacture, OEM can sell the waste products to the remanufacturer, OEM can control the price and the quantity of the waste product which have impacts on the price of the remanufactured product, this is a Stackbelberg model between OEM and remanufacturer which is denoted as mode B, OEM is a leader, and remanufacturer is a follower. If collective recycling obligation is used, OEM need give some recycling fee, so OEM do not care the recycling problem, the third party which is authorized by the government do the work about recycling, and sell the waste product to the remanufacturer, at this time there is no direct relationship between OEM and remanufacturer, this is a Cournot model which is denoted as mode C.

Analysis of Three Modes of Recycling and Remanufacturing

Ω_r is the carbon emissions of each remanufactured product in the manufacturing process. Ω_h is the unit carbon emissions of the waste product in the recycling process. c_r is the unit cost of production of remanufactured product; d is the recycling fee of waste product; ρ is the recycling rate; γ is the remanufacturing rate; Π_i^j is the profit in the second stage, $i \in (OEM, R)$, $j \in (A, B, C)$. We have the following assumptions: (1) The process of selling new product is the same as the process of selling remanufactured product, so the carbon emissions of selling the remanufactured product Ω_s which is equal to the new product. (2) OEM and third-party recycler sell the waste product to remanufacturer at recycling cost. We also give the constraint which is used in the following part, $\gamma\rho q_1^* \geq q_r$ is the condition which is must be satisfied in the second stage. It ensures that the need of the remanufactured product is less the supply.

Mode A

If Mode A is used, OEM sells new product to customers, and at the same time recycles the waste product which is generated in the first stage, then remanufacturing is continuing, and sell the re-manufactured product. In this process the carbon tax is imposed by the government according to the emissions of carbon. The process of Mode A is shown in figure 1.

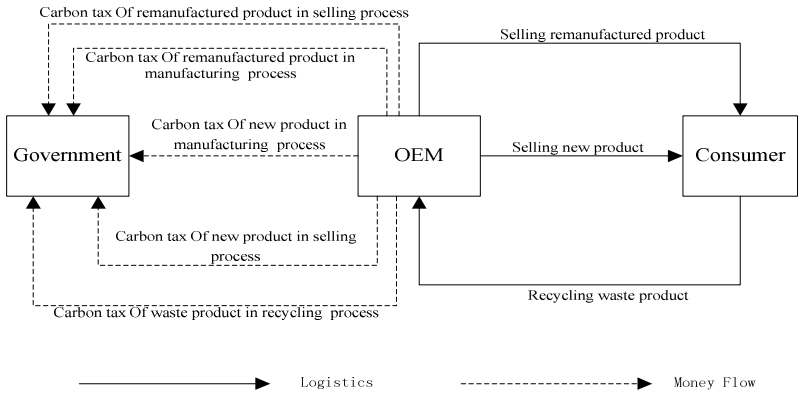

Figure1.Schematic diagram of Mode A

OEM profit function can be expressed as

$$\Pi_{OEM}^{A} = (p_n - c_n)q_n + (p_r - c_r - d)q_r - d(\rho q_1^* - q_r) - \Omega_n q_n t - \Omega_r q_r t - \Omega_s q_n t - \Omega_s q_r t - \rho q_1^* \Omega_h t \quad \text{s.t.} \quad \gamma\rho q_1^* \geq q_r \tag{8}$$

The optimal solution can be obtained using Lagrange multiplier method

$$q_r^{A*} = \gamma\rho q_1^* \qquad q_n^{A*} = \frac{1}{2} - \frac{1}{2}c_n - \beta\gamma\rho q_1^* - \frac{1}{2}\Omega_n t - \frac{1}{2}\Omega_s t$$

$$p_n^{A*} = \frac{1}{2} + \frac{1}{2}c_n + \frac{1}{2}\Omega_n t + \frac{1}{2}\Omega_s t \quad p_r^{A*} = \frac{1}{2}\beta(1 - 2\gamma\rho q_1^* + 2\beta\gamma\rho q_1^* + c_n + \Omega_n t + \Omega_s t) \tag{9}$$

Theorem 1: Equation (9) is the optimal price and sales of the new product and remanufactured product in Mode A. Theorem 1 shows that: (1) The price of new products is related to the manufacturing cost of new product c_n, the carbon emissions of new product in manufacturing process Ω_n, the carbon emissions of new product in selling process Ω_s and the carbon tax t, but not related to the carbon emissions of waste product in recycling process Ω_h. (2) The price of remanufactured product is related to manufacturing cost of new product c_n, the carbon emissions of new product in manufacturing process Ω_n, the carbon emissions of new product and remanufactured product in selling process Ω_s, the carbon tax t, the evaluation index of customers about remanufactured product β, recovery rate ρ and remanufacturing rate γ, but not related to remanufacturing cost c_r, the carbon emissions of remanufactured product in remanufacturing process Ω_r and the carbon emissions of waste product in recycling process Ω_h. (3)$q_n^{A*} \leq q_1^*$ shows that remanufactured product make a cannibalization of the new products in the market share, but $q_n^{A*} + q_r^{A*} > q_1^*$ shows that remanufacturing which mixing market strategy with new product and remanufactured product can expand market share.

Mode B

If Mode B is used, OEM sells new products to customers, and at the same time recycles the waste product which is generated in the first stage, but OEM do not choose remanufacturing, OEM sells the waste product to remanufacturer, remanufacturing is done by the remanufacturer, and then remanufacturer sells the remanufactured product to customers. In this process, OEM and remanufacturer need pay carbon tax according to the carbon emissions. The process of Mode B is shown in figure 2.The profit functions of OEM and can be remanufacturer expressed as

$$\Pi_{OEM}^{B} = (p_n - c_n)q_n - d(\rho q_1^* - q_r) - \Omega_n q_n t - \Omega_S q_n t - \Omega_h \rho q_1^* t - \Omega_s \gamma \rho q_1^* t$$
$$\Pi_{R}^{B} = (p_r - c_r - d)q_r - \Omega_r q_r t - \Omega_s q_r t \quad \text{s.t. } \gamma\rho q_1^* \geq q_r \tag{10}$$

The optimal solution can be obtained using Stackbelberg method

$$q_n^{B*} = \frac{1}{2} - \frac{1}{2}\beta\gamma\rho q_1^* - \frac{1}{2}c_n - \frac{1}{2}\Omega_n t - \frac{1}{2}\Omega_s t \quad q_r^{B*} = \gamma\rho q_1^*$$

$$p_n^{B*} = \frac{1}{2} + \frac{1}{2}c_n - \frac{1}{2}\beta\gamma\rho q_1^* + \frac{1}{2}\Omega_n t + \frac{1}{2}\Omega_s t \quad p_r^{B*} = \frac{1}{2}\beta(1 - 2\gamma\rho q_1^* + \beta\gamma\rho q_1^* + c_n + \Omega_n t + \Omega_s t) \tag{11}$$

Theorem 2: Equation (11) is the optimal price and sales of the new product and remanufactured product in Mode B. We can get the followings by comparing Theorem 1 and Theorem 2: (1) $p_n^{A*} > p_n^{B*}$ shows that the optimal price of new product if remanufactured by OEM is more than by remanufacturer. (2)$q_n^{A*} < q_n^{B*}$ shows that the sales of new product if remanufactured by OEM is less than by remanufacturers.(3)$p_r^{A*} > p_r^{B*}$ $q_r^{A*} = q_r^{B*}$ show that the price of remanufactured product if remanufactured by OEM is more than by remanufacturers, and the sales of remanufactured product if remanufactured by OEM is equal to by remanufacturers.

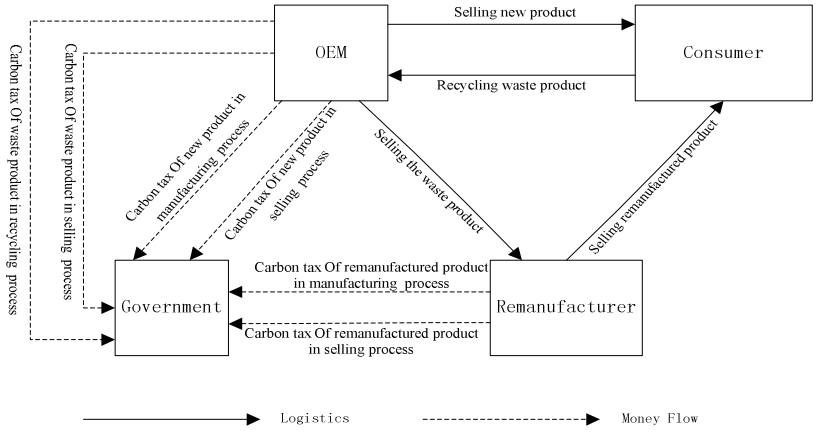

Figure2.Schematic diagram of Mode B

Mode C

If Mode C is used, OEM is not responsible for recycling, the recycling work is done by the third party who is assigned by the government, OEM do not care the recycling work after recycling fee is paid for. The third party sells the waste product to the remanufacturer. In this process, OEM, remanufacturer and the third party need pay carbon tax according to the carbon emissions. The process of Mode C is shown in figure 3.

The profit functions of OEM and can be remanufacturer expressed as

$$\Pi_{OEM}^{C} = (p_n - c_n)q_n - d\rho q_1^* - \Omega_n q_n t - \Omega_s q_n t \quad \Pi_R^C = (p_r - c_r - d)q_r - \Omega_h \rho q_1^* t - \Omega_s \rho q_1^* t$$
$$\text{s.t.}\gamma\rho q_1^* \geq q_r \tag{12}$$

The optimal solution can be obtained using Cournot method

$$q_n^{C*} = \frac{1 - \beta\gamma\rho q_1^* - \Omega_n t - \Omega_s t - c_n}{2 - \beta} \quad q_r^{C*} = \gamma\rho q_1^*$$

$$p_n^{C*} = \frac{1 - \beta + \Omega_n t + \Omega_s t + c_n + \beta^2\gamma\rho q_1^* - \beta\gamma\rho q_1^*}{2 - \beta} \quad p_r^{C*} = \frac{\beta(1 - \beta + \Omega_n t + \Omega_s t + c_n + 2\beta\gamma\rho q_1^* - 2\gamma\rho q_1^*)}{2 - \beta} \tag{13}$$

Theorem 3: Equation (13) is the optimal price and sales of the new product and remanufactured product in Mode C. We can get the followings by comparing Theorem 1, Theorem 2 and Theorem 3:(1)$p_n^{A*} > p_n^{B*} > p_n^{C*}$ $q_n^{A*} < q_n^{B*} < q_n^{C*}$ show that the impact about market share of remanufactured product on new product in Mode A is the largest, in Mode C is the least.(2)$p_r^{A*} > p_r^{B*} > p_r^{C*}$ $q_r^{A*} = q_r^{B*} = q_r^{C*}$ show that the remanufactured profit of OEM in Mode A is more than the profit of remanufacturer in Mode B and Mode C. (3) In the three modes, environment awareness β

has impact on the new product and remanufactured product. With the increasing of environmental awareness, then the competitiveness of remanufactured product will increased gradually, the profit of remanufactured product will also increase, this be a huge opportunity for OEM, so OEM will more be inclined to recycle and remanufacture by themselves.

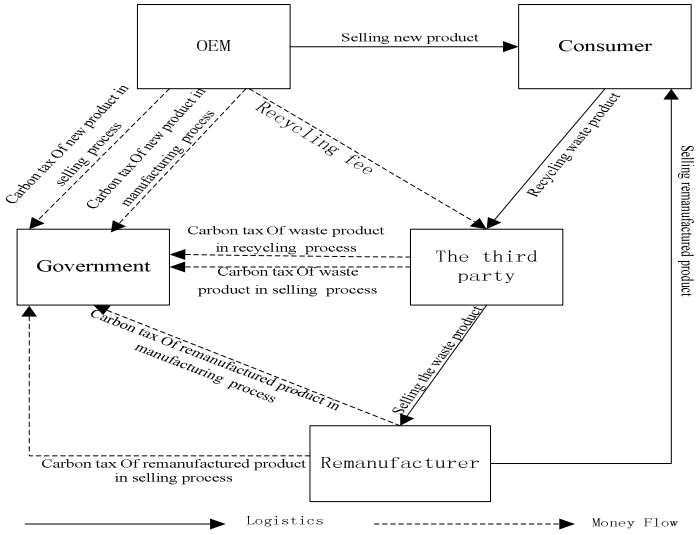

Figure3.Schematic diagram of Mode C

Conclusions

It is very important to design motivating policy about carbon emissions for OEM, remanufacturers and government. The impact of carbon tax on three modes is considered and three modes are analyzed in our paper. Our research shows that the carbon emissions of new product in manufacturing and selling process have impact on the optimal price and sales of the new product in the second stage, but is not related to the carbon emissions in recycling process. Second, with the increasing of environment awareness, OEM will be more inclined to recycle and remanufacture by themselves.

Keywords: Rainfall erosivity; soil erosion; Bailong River Basin; spatial and temporal distribution.

Abstract: Rainfall erosivity is one of the key parameters that determine soil erosion, sediment yield, and water quality, thus its importance has grown in modeling of the environmental effects of climate change. The spatial and temporal distribution of rainfall erosivity in the Bailong River Basin in China's Gansu Province were analyzed. We derived a rainfall erosivity map based on data from 18 meteorological stations in and around the basin using the inverse distance weighting interpolation approach. The annual mean rainfall erosivity within the Bailong River Basin was 798.8 MJ mm ha^{-1} h^{-1} yr^{-1}. The mean annual amount of erosive rainfall accounts for 36.0 to 47.1% of annual precipitation, depending on the station. Rainfall erosivity was greatest from June to September, and rainfall during this period accounts for 77.7% to 84.8% of the total annual rainfall erosivity.

Introduction

Soil erosion has become increasingly strong in response to global climate warming and associated changes in rainfall regimes, and this problem has been exacerbated by human activities that expose soil to erosion by damaging the natural ecological balance. Currently, soil erosion by water is one of several major environmental problems around the world, and especially in China. Soil erosion is particularly severe in western China, where it affected 2.97×10^6 km^2, accounting for 83.1% of the total area of erosion in China. Rainfall is one of the main factors that drive soil erosion, leading to problems such as decreased agricultural productivity, increased frequency and severity of debris flows, and ecosystem damage. Rainfall erosivity represents the potential of rainfall to cause soil erosion, and is determined by a combination of rainfall intensity, rainfall duration, and other parameters (Zhang et al. 2002a). Rainfall erosivity comprehensively reflects the effects of splash erosion by raindrops and the effects of runoff on the soil. Raindrops induce a lower or greater degree of downslope transport of soil particles, depending on their energy and the intensity of the rain, and runoff can also scour the surface; the combination can cause large losses of soil (Silva 2004). At present, rainfall erosivity is the most common quantitative index used to estimate soil erosion, including in prominent and widely used models such as the Universal Soil Loss Equation.

Sukhanovski et al. (2002) proposed a new index to estimate rainfall erosivity based on a physically based description of the erosional characteristics of an artificial rain, the A index, which was developed with the use of methods of continuum media mechanics. Although many models have been proposed around the world to estimate rainfall erosivity using various precipitation parameters, each model was adapted to a specific region. It is clear that many factors that vary among regions can affect the calculation of rainfall erosivity, including climatic conditions. The objectives of the present study were to evaluate the spatial and temporal distribution of rainfall erosivity in the study area, using the Bailong River Basin as a case study, and to analyze the relationship between rainfall erosivity and debris flow activity from a semi-quantitative perspective.

Methods

There are many models for calculating *R* in different regions based on annual, monthly, or daily rainfall data. In this study, we computed the annual *R* using the daily precipitation model proposed by Zhang et al. (2002b), as data with the required temporal resolution was available and the method has been widely applied to estimate rainfall erosivity in China (Cheng et al. 2009). The formula is as follows:

$$R_i = \alpha \sum_{j=1}^{k} \left(P_j\right)^{\beta} \tag{1}$$

$$\alpha = 21.586\beta^{-7.1891} \tag{2}$$

$$\beta = 0.8363 + \frac{18.144}{P_{d12}} + \frac{24.455}{P_{y12}} \tag{3}$$

Where R_i is the rainfall erosivity value in half-month i (MJ mm ha^{-1} h^{-1} yr^{-1}), k is the number of days in half-month i, and P_j is the rainfall on the jth day in half-month i. P_j equals the actual rainfall if the rainfall is greater than the threshold value of 12.0 mm; otherwise, P_j equals zero. The terms α and β are parameters of the model. P_{d12} is the mean daily precipitation for all rainfalls greater than 12.0 mm and P_{y12} is the yearly mean precipitation for days with precipitation greater than 12.0 mm. Table 2 shows the values of α and β parameters for the 5 stations in the Bailong River Basin and the 13 stations surrounding the basin.

The point estimates of rainfall erosivity generated using data from the 18 meteorological stations were interpolated by means of inverse distance weighting to produce a map of erosivity for the basin. Angulo-Martinez et al. (2009b) and Xin et al. (2011) had used the inverse distance weighting interpolation method to obtain the rainfall erosivity map, and this approach performed best for their study area.

Results and Discussion

Daily Rainfall Data

The rainfall database consists of data provided by the National Meteorological Information Center of China from 5 meteorological stations within the Bailong River Basin and 13 meteorological stations around the study area. Each station provided continuous daily precipitation records that we used to compute the rainfall erosivity (*R*), which we used to analyze the spatial and temporal distribution of rainfall erosivity in the Bailong River Basin. The stations have continuous rainfall records ranging from 32 to 55 years. Daily rainfall data provide more detailed information on precipitation variations than yearly or monthly data, and are therefore more useful for computing rainfall erosivity (Xin et al. 2011). We chose 12.0 mm of daily rainfall as the threshold for erosive rainfall in our study area. Although these authors did not test whether this threshold varied from slope classes.

Spatial Distribution

Figure 1 shows the spatial distribution of the average rainfall erosivity in the Bailong River Basin calculated using inverse distance weighting interpolation method and the *R* values based on periods of 32 to 55 years. *R* decreases gradually from the southeast towards the northwest, in accordance with the rainfall distribution along this direction. Moreover, the value of *R* increases moving downstream, with the exception of an area surrounding Zhouqu. The rainfall erosivity for most of the areas within the basin ranged between 800 and 1100 MJ mm ha^{-1} h^{-1} yr^{-1}, including the areas around Diebu and Dangchang, and some parts of Wudu and Wenxian, which together account for about 70% of the total area of the basin. The rainfall erosivity for the areas around Zhouqu and Wenxian ranged between 500 and 800 MJ mm ha^{-1} h^{-1} yr^{-1}. Zhouqu had the lowest value within the basin (504.5 MJ mm ha^{-1} h^{-1} yr^{-1}). However, Zhouqu is one of the areas within the basin that is at highest risk of geological disasters such as debris flows and landslides and the soil losses in this area are serious. These results suggest that the rainfall erosivity and the rate of debris flows and other disasters are inversely correlated. The rainfall erosivity was significantly negatively correlated

with the occurrence of debris flows (R^2 = 0.15, P<0.05). There are several possible explanations for this seeming contradiction. First, the climate in the Zhouqu area differs greatly from that of other areas. The ability of rainfall to cause erosion is calculated based on the average annual precipitation and does not account for extreme precipitation events. Therefore, the results in Figure 1 differ somewhat from the actual status. In addition, the lithology of the Zhouqu area is relatively stable compared with that of other areas in the basin. The vegetation cover is also higher than that in any other areas, and the rock strata are less broken than in any other areas. Furthermore, rainfall of 12 mm at a site with a coarse sandy soil and gentle slopes may not cause any erosion; whereas the same rainfall at a site with a compact clay soil and steep slopes may cause severe erosion.

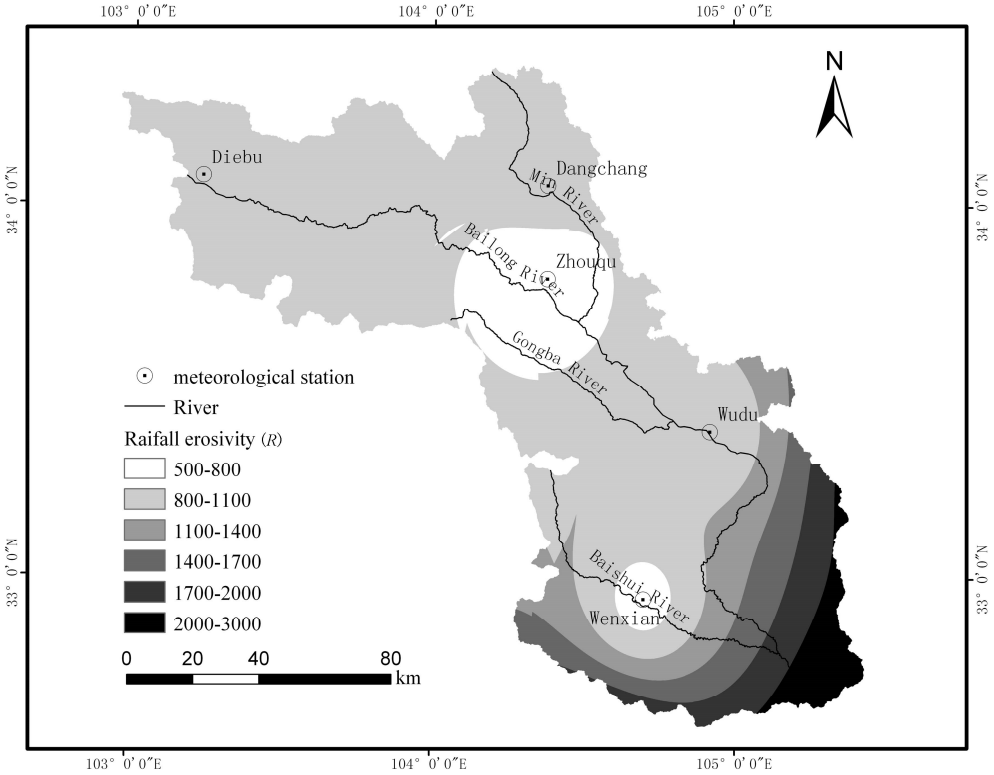

Figure 1 Rainfall erosivity map of the Bailong River Basin based on inverse distance weighting interpolation of the *R* values from the 18 meteorological stations.

The reasons for the low occurrence of debris flows in the Wenxian area are because of the low degree of fracturing of the rock, the high vegetation cover, and appropriate weather conditions. The reasons why the Bailong River Basin is one of the four areas with the highest occurrence of geological disasters in China include the high mountains, steep slopes, relatively low degree of vegetation cover, deep valleys, high frequency of extreme rainstorms, and the serious soil loss due to the fragile ecological environment. Soil loss can exacerbate the frequency of debris flows in our study area because it reduces the amount of soil available to absorb rainfall, leading to increased surface flows and the concentration of these flows in low-lying areas. Another possibility is that the areas with the highest risk of debris flows due to steep slope, low vegetation cover, and other factors may have lost all or most of their erodible material in previous debris flows. Thus, insufficient debris remains to be carried along by flowing water.

It is important to note that rainfall erosivity only represents the potential for erosion. Whether erosion and debris flows actually occurs depends on whether erodible material is present, and whether other factors such as slope allow the falling water to transport this material. However, the spatial distribution of rainfall erosivity is not consistent with the actual status of soil loss. The differences between the spatial distribution of rainfall erosivity and the spatial distribution of soil erosion demonstrate that the rainfall erosivity can only explain some of the variations in soil erosion caused by rainfall. This conclusion agrees with the results of Silva (2004), who reported that rainfall erosivity accounted for about 80% of the variation in soil loss in Brazil. However, some areas within the basin exhibit a stronger correlation between rainfall erosivity and the actual status of soil

erosion. For example, the red area in Figure 1 that stretches from north of Wudu to south of Wenxian (with a rainfall erosivity ranging from 1100 to 1400 MJ mm ha^{-1} h^{-1} yr^{-1}) in Beiyu River district in Wudu has a complicated geological structure and highly fractured rock. Local records indicate that geological disasters such as debris flows have occurred annually in this area, and that the soil loss in this area is serious.

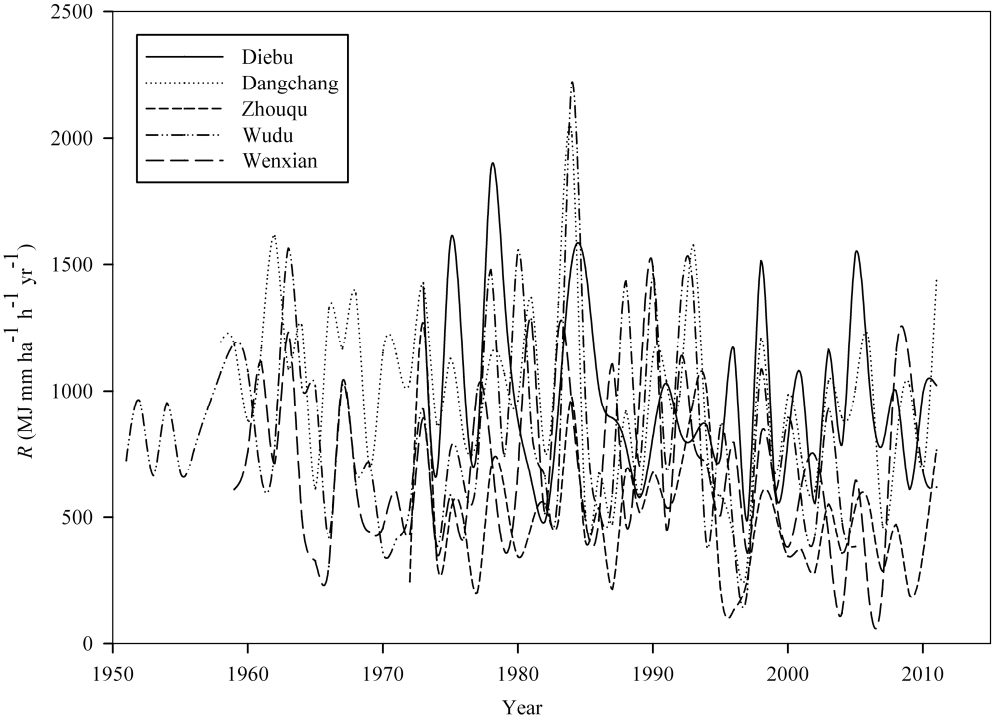

Figure 2 Annual variability in rainfall erosivity (*R*) in the Bailong River Basin.

Temporal Variation of Rainfall Erosivity

Annual rainfall erosivity changes dramatically over time, with high inter-annual variability at all five stations within the basin (Fig. 2). The differences between the stations are large and the ratio between the maximum and minimum *R* values at a given station ranged between 3.88 and 12.54, with coefficients of variation (CV) ranging between 1.10 and 1.21 (Table 1). This degree of variation is higher than in previous research, which reported coefficients of variation of about 0.5 in a typical small basin in the Three Gorges Reservoir area of China (Sun et al. 2011) and at some stations in Switzerland (Meusburger et al. 2012). This difference probably resulted from differences in the rainfall and other climate factors between study areas. The values of rainfall erosivity at different stations changed significantly over time. The values at all five stations have shown a downward trend during the study period. Within the basin, the decrease in rainfall erosivity ranged from 6.65 MJ mm ha^{-1} h^{-1} yr^{-1} at Danchang to 1.32 MJ mm hm^{-2} h^{-1} yr^{-1} at Wenxian. This trend is similar to the trend for annual rainfall volume. These parallel trends explain why the rainfall erosivity in the Bailong River Basin appears to have been decreasing during the study period.

TABLE 1 VARIATIONS IN ANNUAL RAINFALL AND ANNUAL RAINFALL EROSIVITY IN THE BASIN

Station	Length of record (yr)	Annual rainfall (mm)			Erosive rainfall (mm)[a]	Annual rainfall erosivity (MJ mm ha^{-1} h^{-1} yr^{-1})			
		Average	Max.	Min.		Average	Max.	Min.	Cv[b]
Dangchang	54	580.4	775.7	388.3	263.7	987.3	2011.9	319.8	1.10
Diebu	39	572.1	762.0	416.5	269.3	980.3	1874.9	482.7	1.18
Wenxian	53	442.3	671.9	290.9	184.9	684.8	1491.9	119.8	1.16
Wudu	55	468.6	689.3	270.5	215.5	837.3	2219.9	216.6	1.21
Zhouqu	40	424.4	561.5	303.4	152.8	504.5	1267.7	133.7	1.18

[a] Erosive rainfall was defined as total rainfall greater than 12.0 mm in a single event.
[b] CV, coefficient of variation.

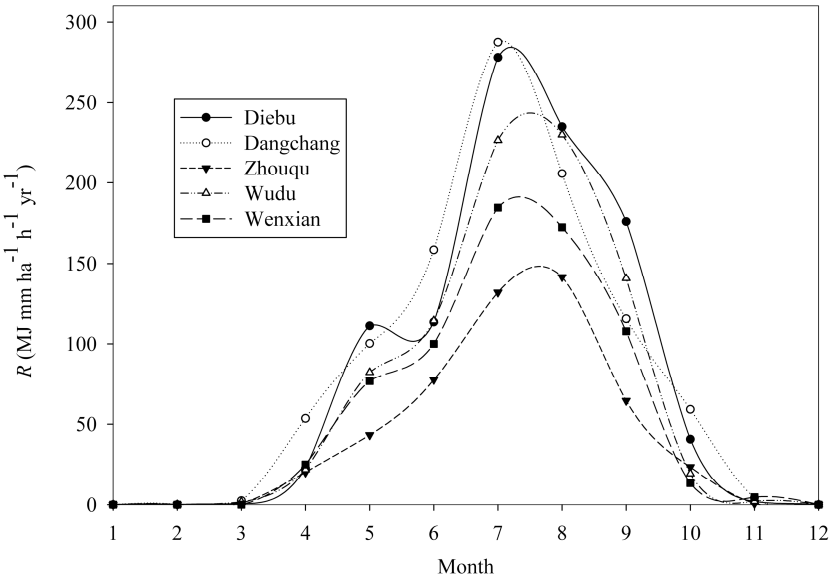

Figure 3 The distribution of rainfall erosivity (*R*) throughout the year at the five meteorological stations in the Bailong River Basin.

Figure 3 shows the distribution of rainfall erosivity throughout the year based on the proportion of the total annual value in each month. The erosivity reached its highest values during the summer, and showed a monomodal distribution. The rainfall erosivity between June and September accounted for 77.7 to 84.8% of the total annual value. Including the May value increases this proportion to 87.9 to 94.6% of the annual total. The peak values generally occurred in July and August, and these two months accounted for 50.0 to 54.4% of the annual total. The distribution of *R* values follows the overall distribution of precipitation during the year. The distinct increasing trend for rainfall erosivity between May to September agrees with climate change predictions, which forecast reductions in average summer rainfall but increases in high-intensity rainfall events for many parts of Central Europe and the Alps (Frei et al. 2006; Meusburger et al. 2012). The rainfall erosivity values are low in January, February, March, November, and December and because these values account for only 0.3 to 0.7% of the annual total, they can essentially be ignored. The values are low because there is hardly any rainfall or snow in the winter and spring in these areas.

Conclusions

We mapped rainfall erosivity in the Bailong River Basin using the inverse distance weighting interpolation method based on data from 18 meteorological stations in and around the basin. Rainfall erosivity is one of the key input parameters that determines soil erosion, sediment yield, and water quality modeling, but in our study area, it is particularly important as a potential predictor of the occurrence of debris flows, which occur frequently and pose a serious risk to human life and infrastructure such as roads and electrical power lines.

Rainfall erosivity increases gradually from the northwest to the southeast, in parallel with changes in the rainfall distribution. The rainfall erosivity in most areas of the basin (about 70% of its area) is between 800 and 1100 MJ mm ha^{-1} h^{-1} yr^{-1}. The rainfall erosivity was highly variable both between stations and over time. However, all stations showed a trend of decreasing erosivity in recent years as a result of decreasing annual rainfall. Rainfall with erosive potential accounted for 36.0% to 47.1% of the annual total. All stations demonstrated a positive correlation between annual precipitation and annual rainfall erosivity. The results suggest that in complex terrain like that of our study area, *R* is not an adequate predictor of the probability of erosion. To determine that probability, it will be necessary to include the values of other parameters such as vegetation cover, slope, and soil texture in a predictive equation. We hope to perform these calculations in our future research.

Acknowledgments

This study was funded by the National Key Technology R&D Program (No. 2011BAK12B05).

Keywords: Gold deposit, characteristics of process mineralogy, occurrence of Au, Nali, Guangxi.

Abstract. Using the analysis techniques of polarizing optical microscope and electron probe, mineral composition, ore texture and structure and the occurrence of Au in the primary ore are studied. The research shows that the main ore minerals in the ore include realgar, pyrite and arsenopyrite etc. Sulfur-stibarsen is the main carrier of Au, and is the major associated mineral of realgar, surrounded mainly by realgar, and partly is the associated mineral of arsenopyrite. The existence of visible gold and microscopic gold in the ore of this mining area can be excluded, and the gold might exist mainly in the form of inclusion gold, which is the so-called "nano-Au".

Introduction

Nali gold deposit is located at Yanjiang, Long'an County, northwest 120km of the capital of Guangxi Zhuang Autonomous Region, Nanning, belonging to the extension of the ore bodies in Leiyaoling orefield. After a comprehensive study of the characteristics of process mineralogy, the mineral composition, texture, structure of the primary deposit and the main occurrence state of the useful associated elements are revealed, which provide scientific basis for the selection of the metallurgical program.

Geological Background

Tectonically, the study area is in the gold mineralization belt of southwest Guangxi, well developed with numerous faults. NE trending faults are the major structures in the Nali gold region. Since Triassic, the sedimentary stratum of the upper crust of the Youjiang rift basin and its expansion zone is very thick, which is made up of the upper structural layer of the Youjiang basin and the lower structural layer of the platform. The thick sedimentary stratum leads to the mineralization products covered or deeply buried so that there are a lot of tectonic magmatic belts. These factors provide favorable conditions for the formation of gold deposits, showing a large ore prospect in the deep part of Nali gold deposit, while the prospecting task is rather tough [1].

The orefield, with several fold structures and fault structures, is located in the area of the south China paraplatform, which is in the Youjiang regenerated geosynline. The fault structures developed in Neilu syncline axis is interlayer fracture zone. There are some small folded rock formations, small scale lenticular ore bodies and few magmatic activities. The Triassic formations are well-exposed in this area but the Tertiary strata is just exposed in the southwest of the orefield.

The wall rock alterations closely associated with gold mineralization are silicification, pyritization, kaolin, fade, sericitization and carbonatization. The certain size and occurrence of the ore body provide favorable conditions for the prospecting.

Ore Characteristics

The gold orebody and occurrence of the research area mainly occur in the sand mudstone interlayer fracture zone of the middle Triassic series Lanmu group. Surrounding rocks of ore body composed of cataclastic rock, tectonic breccia and so on. The original rocks are powder sandstone, mudstone and silty mudstone shale. The main ore-bearing rocks are cracked rock, muddy siltstone and silty mudstone, along with middle-weak silicification and limonite. The colors of the original rocks are brown yellow, gray, light gray, experienced intense metamorphism.

Ore Mineral Characteristics

Realgar, pyrite and other metal minerals are quite visible in hand specimen. Microscope shows that the major ore minerals in the rock are realgar, arsenopyrite, pyrite, chalcopyrite and so on, accounting for about 15%-35%, some samples are about 10%, while the main ore mineral of the rock is realgar.

Realgar fills the rocks as veins, granular aggregates form, whose content accounts for roughly 50%-75% of the total amount of ore minerals, due to affecting by the pyrite alteration, the edge and internal of realgar have significantly grown limonite alteration, and the iron are enriched. Parts of realgar intersperses in the late quartz veins, then the late quartz veins are separated by realgar. There are also a small amount of realgar ore veins covering the surface of the late quartz veins, indicating that the area has undergone multi-stage tectonic movements. After the formation of hydrothermal quartz veins, ore contained fluids added in, resulting in the ore enrichment in this area. Pyrite is mainly subhedral and anhedral, and sometimes hexagonal, hexagonal granulars can be seen, very few are irregular cataclastic or disseminated, particle sizes are quite different, the maximum can reach to 0.2mm, whereas some particles are difficult to detect under the powerful microscope, only can be observed in the high magnification image of electron microprobe, but the vast majority of particles concentrates mainly in 0.05-0.15mm, the average particle size is less than 0.10mm, accounting for 20%-45% of the total content of the ore. Arsenopyrite are unevenly distributed in the ore, a small portion is surrounded by realgar, particles are generally smaller and the content is less, most of them are crushed in cataclastic structure, accounting for about 5% of the total content of ore, crystal has been basically destroyed, basic illegible, a few short columnar grain crystal fragmentation filled with clay minerals, and the arsenopyrite and pyrite can be seen co-existed.

Characteristics of the Gangue Minerals

The main gangue minerals are quartz, feldspar, mica, clay minerals and carbonate minerals, in which sericite is mainly in the mica mineral, with a certain amount of hydromica, and a little biotile and muscovite; clay minerals and carbonates are even less.

There are two types of quartz: firstly, quartz in the terrigenous detrital with relatively small particles; secondly, debris filled the late hydrothermal fluids, along the fractures filled with quartz veins, due to the late hydrothermal filling then partly detrital quartz grains regrowth makes the crystal become larger, so that the particle diameter is relatively coarse. The content of quartz can be accounted for roughly 40%-60% of the total rock, particle sizes vary largely, the maximum can reach about 0.7mm, and the smallest are the quartz particles in the debris. The vast majority of feldspar are already developed more intense alteration, transformed into sericite, clay and other minerals, the place of the local alteration can see the feldspar alteration residual particles, approximately accounting for 10%-30% of the total rocks; due to the alteration, mineral boundaries blur, particle sizes are generally about 0.1-0.2mm. Sericite, hydromica clay minerals particles are a major component of the matrix and in the samples we can see the mica clay minerals and small amounts of carbonate minerals.

Texture and Structure of the Ore

Ore has cracked, silty, clay, fine and brecciated textures; and has massive and disseminated structures, rocks show certain directional texture. Ore minerals are mainly distributed in the intense

alteration beddings, less developed in quartz veins. The ore minerals are roughly even distributed in the ore, relatively enriched locally, and in the enriched area, pyrite distributes micro-bedding with clay and other darkcoloured minerals.

Based on the electron microprobe (EPMA) and spectroscopy (EDS) analysis of the ore, inside the realgar contains a certain amount of arsenic ,antimony sulfide ore, a small amount of arsenopyrite and chalcopyrite ore minerals, and occasionally accompanied by pyrite. The vast majority of arsenic, antimony sulfide ore is the associated minerals of realgar, basically surrounded by realgar, a small part of what is the associated minerals of arsenopyrite. Due to the extremely low content, chalcopyrite ore and other minerals, accounting for about 1% of the ore minerals, have no substantive effect on the mineralization. In addition, in a few samples we found that pyrite grains contain or semi-contain the smaller arsenopyrite particles, this situation may produce intergrowth when the ore is crushed, but the total quantity is not large, and it has sample inclusion relation with few mineral types, the majority of the mineral particles distributed in the form of monomers ore.

The ore minerals and gangue minerals in the ore are closely. After crushed, due to the particle size becoming smaller, the former connected minerals, split at the interface between the different minerals, then separated to a certain extent. From the mineral texture, except for a few coarse-grained disseminated ore after crushing to get quite a few monomer dissociation tablets, the vast majority of the ore must undergo grinding in order to get a higher degree of dissociation. Since the main mineral ore exists substantially in the form of a monomer, although there are interludes and inclusion relations but few total amount, simple structure, and interspersed with each other and contained the size of the particle aggregates is less different with the particle size of the ore mineral monomer. In addition, due to the gangue minerals contain more hydromica, sericite and other clay minerals, they have high degree of alteration, while its hardness are quite different with ore minerals. The above factors suggest that dissociation of ore minerals is better.

Gold Occurrence and Metallurgical Processes Suggestions

Occurrence

According to the classification of gold mineral granularity, the gold can be divided into visible gold (> 0.2mm), microscopic gold (0.2μm-0.2mm), submicroscopic gold (<0.2μm). And generally consider the submicroscopic gold with size less than 0.1μm (scanning electron microscope can not be detected) as “invisible gold” [2]. The visible gold has not be found through the visual inspection in hand specimen. In addition, the existence of microscopic gold has also not been detected by careful observation of ten specimens under microscope. Therefore, the inexistence of visible gold can be confirmed, and the gold should be existed by the way of “invisible gold”, which is submicroscopic gold and ultramicro gold.

Gold-bearing minerals are found to be metal sulfide by using electron probe analysis. They are realgar, pyrite, arsenopyrite, sulfur-stibarsen and chalcopyrite, and the low content of arsenopyrite and chalcopyrite has little effect on gold mineralization. By analyzing components of ten samples, 47 efficient measuring points are gotten, and 17 points of them contain gold. These 17 points account for about 36% of the total amount of gold. There are 3 gold-bearing measuring points exist in realgar with the gold content of 0.36%-0.61%, averaging at 0.46%. Pyrite has 3 gold-bearing measuring points and the gold content is 0.22%-0.36%, with an average of 0.27%. Sulfur-stibarsen has 11 gold-bearing measuring points and the gold content is 0.08%-1.81%, with an average of 0.54%. The test results can be seen in table 1, showing the highest gold content is 1.81%, and the lowest is 0.08%, averaging at 0.48%, and from which we can find that the content of gold value differs by one order of magnitude, indicating the enrichment in the distribution of gold.

From the result of eleven point in sulfur-stibarsen, the average content of gold is 0.54%, far more higher than the average of the total gold samples, which indicated that the sulfur-stibarsen is the main carrier of Au, occupying 5%-10% of the sulfide and the gold content occupying 80% of the

total; in addition, it's content level differ by one order of magnitude, indicating that the Au in the sulfur-stibarsen also exists a certain enrichment. On the other hand, the sulfur-stibarsen mainly exist in realgar veins and the realgar veins include a certain amount of Au (0.36%-0.61%), thus, the gold mineralization is closely related to the forming of realgar veins.

In order to further identify the occurrence of the Au in these gold-bearing sulfide, electron probe are applied to do lot of line scanning on the thin section, and find that only few gold grains exist, and the gold kurtos is widespread in realgar on mapping of the electron probe X ray; the white dots on the map display the existence of the specified Au and the dots evenly distributed along the realgar position, and cannot find enrichment in other sulfides. It shows that the particle sizes of gold are smiler than the zone of resolution in scanning micro zone of electron probe ($1\mu m^2$). From the results of phase analysis in single mineral, the occurrence of Au is inclusion gold, and the main gold-bearing minerals are sulfur-stibarsen and realgar. From the scattering mapping of electron probe in ore, we can see that the sulfur-stibarsen exist in realgar as inclusions, thus, the comprehensive utilization of the Au and Sb can be considered.

In addition, the gold mainly exists in the form of lattice gold when the content of Au/As less than 0.02; when the content of Au/As is more than 0.02, inclusion gold are produced[2]. In table 1, the content of arsenic in pyrite is 0.13%-0.50% and the average is 0.31%, showing the mineral is arsenic pyrite; the average ratio of Au/As in the pyrite (arsenic pyrite) is fifteen times of cardinal number (0.02), indicating that the occurrence of gold in pyrite (arsenic pyrite) are inclusion gold.

Study on Technological of Gold Bearing Sulfides

Through the above study on occurrence state of gold, gold in the Nali gold deposit mainly exists in the form of inclusion gold, and occur in the carrier of arsenic, antimony sulfide ore, realgar and pyrite (containing arsenic pyrite). Gold particle sizes are micro, dominated by <0.1μm sub-microscopic gold, and a small number is ultra-microscopic gold. The form of gold is mainly irregular and sub-round granular.

Arsenic and antimony sulfide ore, mostly unevenly polyhedral, distributes in realgar edges and interior, whereas realgar fills among the rocks as veins. Late hydrothermal quartz are common interspersed by realgar. Arsenic and antimony sulfide ore and realgar have smooth edges, disseminated with small particles, mainly dominated by fine particles, partly medium grain and particulate, and uniformity is over 90%, belonging to fine-micro particle uniformly disseminated type.

The particle sizes of pyrite (containing arsenic pyrite) is unequal, irregular cataclastic and disseminated distributed between gangue ore in disseminated structures. Gangue minerals are in cubic and polytropic along the distribution of micro-bedding such as clay minerals. Parts of pyrite (containing arsenic pyrite) coexist with arsenopyrite, and barely included in the realgar, the crystals are complete, containing impurities on the surface, disseminated particles are micro, uniformity is below 10%, belonging to fine-medium particle uniformly disseminated type.

Metallurgical Processes Recommended

In view of occurrence and content of gold, and fine gold bearing sulfide dissemination size, C, As, S and other harmful elements are extremely unfavorable to smeltingare, so the conventional cyanideleaching, leaching, amalgamation method can not be applied [3]. This deposit belongs to metamorphic hydrothermal gold deposit, sulfur and arsenic antimony ore are the main carrier minerals of gold with highest gold distribution rate, followed by realgar; therefore, in the gold deposit which sulfide is the main gold bearing minerals, the key factor deciding the recovery rate of Au is the recovery of gold carrier sulfide minerals [4].

Gold in the mining area is in the form of inclusion gold hosted in sulfide, belongs to the refractory gold ores, gold bearing minerals should be fine ground before the flotation, for the micro gold, the size of gold-carry minerals need to be considered, so as to determine the appropriate grinding fineness [5]; to crush the ore, extract realgar and sulfur arsenic and antimony ore, eliminating the gangue minerals as much as possible. These sulfides are usually undissolved in

cyanide solution, nor penetration, making gold uneasy to leaching directly, and the ores must undergo roasting pretreatment before the leaching. Then use the cyanide leaching method to extract, meanwhile, a certain amount of mixed oxidant (H_2O_2 + $KMnO_4$) and mixed additives ($Pb(Ac)_2$ + A) should be added in the process of cyanide leaching.

Roasting pretreatment method is suggested to use microwave roasting, which has the feature of selective heating to useful minerals, different minerals have different absorption and thermal expansion to microwaves, when heating microwaves, some mineral would expand, forming cracks useful for leaching [6]; using microwaves to treat the refractory gold ores, making them decomposed, the included gold would separate from C, As, S minerals, changing the refractory ore to easy to leach. Therefore, microwave roasting can be used as one of the pretreatment methods in this area [7].

As to the above discussion, the following points should also pay attention to: Firstly, although the gangue minerals and metal sulfide intergrowth simply with small total amount, the two dissemination relations still need to pay attention to; Secondly, in order not to affect the gold leaching, clay minerals, dark minerals, water soluble minerals are generally difficult to fine grinding, filtration and sedimentation, dissemination and cleavage characteristics should be considered [8]; Thirdly, carbonate minerals altered from mica minerals exist in this area, with small content, the individual samples accounted for about 5%-8% of the total, the CO_3^{2-} ions consume lots of acid, which will also affect the cyanide leaching of gold [5].

Conclusion

Based on the process mineralogy studies in the primary ore in Nali gold deposit, Guangxi, several main research results are as follows:

(1) Mineral assemblage: the main ore minerals related closely to gold mineralization as follows: sulfur-stibarsen, realgar, and pyrite. Most sulfur-allemontite occurs in inner realgar but few in the edge of realgar, the two minerals are co-occurred. In addition, there is a small amount of pyrite coexistent with arsenopyrite.

(2) Texture and structure: the ore minerals like realgar, pyrite and arsenopyrite distribute evenly in the ore, and enriches locally. Realgar occurs as veinlet, filling the rock fractures; pyrite occurs as disseminated structure and distributes in the ore irregularly; Most of arsenopyrite occurs as xenomorphic monomer in the ore with small particle sizes, and partly are altered, being difficult to identify. Due to the reasons of few interpenetrations and inclusion relationship of minerals, simple structures, high alteration and so on, the degree of separation is good.

(3) Occurrence: Synthesizing former work, all the ore in this area are oxidized ore, and the main useful components are Au with low grade, but locally enriched. Through detailed study of 10 samples, the existence of visible gold and microscopic gold in ore of this area can be excluded. The gold is mainly the submicroscopic gold and little ultramicro gold, and occurs as inclusion gold.

Acknowledgments: the field work of this article accomplished in the help of Guangxi No.4 geological brigade, and the indoor work gets strong support from Fundamental Science on Radioactive Geology and Exploration Technology Laboratory (ECIT).

Keywords: deficit irrigation; winter wheat; root; canopy; grain yield

Abstract: In order to investigate the optimal water-saving and high-efficient irrigation patterns of winter wheat in North China Plain, during 2010—2011 and 2011—2012 winter wheat growing seasons, 3 irrigation treatments were conducted, i.e., irrigated 120 mm only at jointing stage (T1), irrigated 120 mm only at heading stages (T2), and irrigated 60 mm each at jointing and heading stages (T3), respectively, to study the effect of deficit irrigation on root-shoot development and grain yield of winter wheat in North China Plain. The results showed that under the condition of irrigated 120 mm during the winter wheat growing season, the treatment which irrigated 60 mm each at jointing and heading stages, the leaf area index significantly (LSD, $P<0.05$) increased at milky stage, which was mainly due to increase the leaf area index at 0—20 and more than 60 cm above the ground surface. The 2 growing season results revealed that dry matter accumulation at maturity stage in T3 was significantly (LSD, $P<0.05$) higher than those in T1 and T2. Compared with T2, the root length density in T1 and T3 were significantly (LSD, $P<0.05$) higher below the ground surface 50 cm. The results indicated that irrigated 60 mm each at jointing and heading stages during the winter wheat growing seasons, grain yield was the highest, which could be attributed to significantly (LSD, $P<0.05$) increase the spike numbers. Under the condition of irrigated 120 mm during the winter wheat growing seasons in North China Plain, it is suggests that winter wheat should be irrigated 60 mm each at jointing and heading stages, to achieve reasonable water use efficiency and grain yield.

Introduction

The North China Plain is one of the most important grain production areas of China; high and stable grain yield of winter wheat is very important to ensure food security of China. However, water resources are limited in this region [19]. Water resource of per capita is only 790 m^3. Hence, how to improve water use efficiency of winter wheat in this region is the key of stable and high grain yield.

The crop's reasonable canopy structure is the important factors for ensuring high and stable crop production [18]. Canopy has the important influence on crop dry matter accumulation above the ground surface and economic output [3]. Li et al. [10] showed that planting patterns could change in the vertical distributions of leaf area index; hence, the canopy structure was improved. Under filed conditions, crop growth is dependent on the ability of the canopy to intercept incoming radiation, which is function of leaf area index and canopy structure, and convert it into biomass. The difference of winter wheat canopy structure influence the light distribution in crop colony, as a result, leading to difference of the grain production[5,9] .

Root system is the absorption organs of moisture and nutrient for the plant in agricultural production, its research increasingly brought to the attention of the agricultural scientific research workers. Studies have shown that the different water conditions have significant influence on the spatial and temporal distribution of winter wheat root system, soil water utilization, and grain yield[13,17] . Therefore, maintaining rational canopy and enhancing root system absorbing power are the premise of ensuring crops grain yield.

For the importance of food production in North China Plain and the shortage of water resources, the amount of research about deficit irrigation in this region is growing [6,11,15] , but the research on root-shoot development of winter wheat is few.

This study aims to determine the effect of deficit irrigation on the canopy structure and grain yield of winter wheat, which could provide the theory basis and technical support for stable and high grain yield of winter wheat under the condition of deficit irrigation.

MATERIAL AND METHODS

A. Experimental site

The study area was located at Dong lufang village, Anzhan town, Feicheng City, (36°43′48″N,116° 45′ 32″E). The plot areas were warm temperature semi-humid and semi-arid climate zones, where the mean precipitation is 697 mm, approximately 70% of which is received from June to September, that is, the summer maize growing season. During the growing season of winter wheat, precipitation amount is only 30% of the mean annual precipitation. The precipitation under natural conditions for the winter wheat growing seasons in 2010 and 2011 were 172.2 and 208.4 mm, respectively. The concentrations of nitrogen, rapidly available potassium, and phosphorus at a depth of 0－20 cm below the ground surface were 80, 15 and 15 mg/kg, respectively.

Winter wheat cultivar “Jimai 20” was manually planted on October 12 in 2010 and on October 17 in 2011, respectively.

B. Experiment Design

In this area, previous studies have shown that winter wheat could get the best grain yield, water use efficiency, and economic benefits under the condition of irrigated 120 mm[10,11] . Therefore, in this study, total irrigation amount was controlled at 120 mm was applied to the treatments as follow: irrigated 120 mm only at jointing stage (T1), irrigated 120 mm only at heading stage (T2), and irrigated 60mm each at jointing and heading stages (T3), respectively. In 2011, the jointing and heading stages were April 7 and May 1; in 2012, were April 9 and April 29, respectively. Water was supplied to the plots from a pump outlet using plastic pipes, and a flow meter was used to measure the amount of water applied.

During the both growing seasons, before sowing, 150 kg hm^{-2} of urea, 300 kg hm^{-2} of Calcium superphosphate (P_2O_5 15%), and 75 kg hm^{-2} of potassium chloride(K_2O 60%) were applied. At jointing stage, 150 kg hm^{-2} of urea was applied.

The area of each plot was 16 m^2, the treatments were randomized using a complete factorial design and were applied in 3 replications. A 1.5-m-wide zone with no irrigation was positioned between the 2 irrigation plots to minimize the effects of the 2 adjacent plots.

C. Measurements

Leaf area index (LAI)

At filling satge, the LAI was determined by sampling small plots consisting of 20 consecutive plants from the central rows, and the LAI above the ground surface of 0–20, 20–40, 40–60, and above the ground surface 60 cm were separated, respectively. Leaf area was calculated by the following equation:

$$\text{Leaf area} = \text{leaf length} \times \text{leaf width} \times 0.78. \quad (1)$$

In the above equation, the leaf length was the distance from leaf pillow to leaf finial, and the leaf width was measured at the widest part of the leaf. The sampling areas were spaced to avoid the effect of previous samplings.

Dry matter accumulation above the ground surface and plant height

From jointing to maturity stage, dry matter accumulation and plant height were measured every 7 days, 20 consecutive plants were sampled. After the plant height was measured, which was placed in the drying owen at 105℃ for 20 minutes. Then, dry matter above the ground surface was determined after drying at 80 ℃ for 72 h.

Root length density

Roots were sampled at maturity stage from soil cores. The diameter of the corer was 10 cm. From each treatments, soil cores were obtained at 10-cm increments down to 180 cm. The cores were then taken to the laboratory, and the soil was manually removed in washing cans. After separating the roots from the debris, root length was measured by using a 1.27-cm grid. The roots were oven dried at 80 ℃ to determine the dry weight.

Grain yield and yield components

Grain yield was measured at maturity by sampling 2 m^2 of each plot. Spike number per m^2, kernel numbers per spike, and thousand kernel weights were determined.

Statistical analysis

Analysis of variance (ANOVA) was used to analyze the effects of the different treatments. ANOVA was performed at a 0.05 level of significance to determine whether the treatments were different. Multiple comparisons were made between the significant effects using the least significant difference (LSD) test at $\alpha = 0.05$.

RESULTS AND DISCUSSION

A. The vertical distribution of LAI

Fig. 1 shows the vertical distribution of LAI on May 2nd in 2011. T3 resulted in the highest LAI, followed by T1, and the lowest LAI was observed in T2.When irrigated only once during the growing season of winter wheat, the LAI over 60 cm above the ground surface were significantly increased at jointing stage in T1 treatment. When irrigated 2 times during the growing season of winter wheat, compared with T1 and T2 treatment, the LAI both at 0–20 cm and over 60 cm above the ground surface were increased significantly in T3 treatment; however, there were not significant effects observed in the LAI at 20–40 and 40–60 cm above the ground surface.

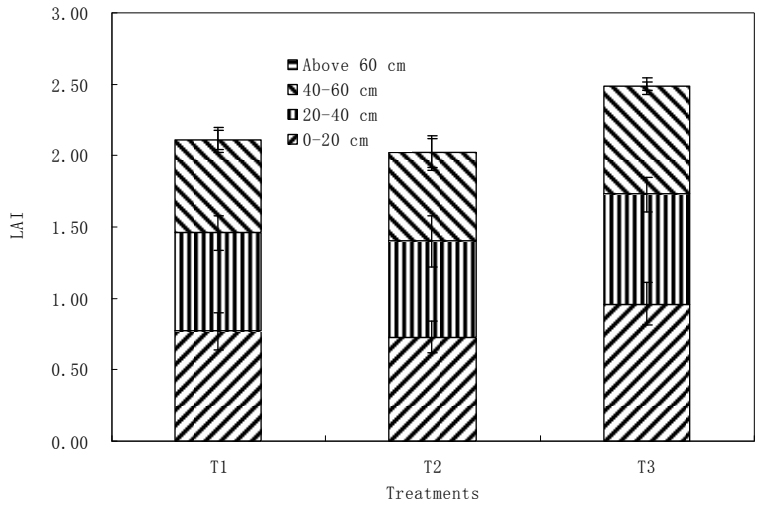

Figure.1 Vertical distributions of LAI in winter wheat canopy

B. Plant height and above ground dry matter

Under the condition of irrigated 120 mm, the plant height and aboveground dry matter were significantly affected by irrigation times and period (Table 1). At jointing stage, in the both growing seasons, the plant height and aboveground dry matter were not significant differences among any treatments. At maturity stage, in 2010–2011, T1 treatment significantly promote the growth of winter wheat; hence, significantly increased plant height. However, the above ground dry matter variation trend was different from that in plant height, the highest aboveground dry matter was found in T3, followed by T1, and the lowest was observed in T2; in 2011–2012, the plant height of T1 and T2 were significantly higher than T2, the variation trend of above ground dry matter in 2011–2012 was similar to that in 2010–2011.

TABLE 1 PLANT HEIGHT AND ABOVEGROUND DRY MATTER AT JOINTING AND MATURITY STAGES DURING WINTER WHEAT GROWING SEASONS IN 2010－2011 AND 2011－2012

Treatments	Jointing stage		Maturity stage	
	Plant Height / (cm)	Aboveground dry matter / (g/cm^2)	Plant Height / (cm)	Aboveground dry matter / (g/cm^2)
2010－2011				
T1	31.72 a	351.47 a	71.15 a	1211.23 b
T2	31.59 a	350.83 a	58.33 c	1050.12 c
T3	31.47 a	347.45 a	69.67 b	1395.03 a
2011-2012				
T1	35.26 a	362.83 a	69.67 a	1220.89 b
T2	32.69 a	362.77 a	61.99 b	1080.92 c
T3	32.63 a	367.25 a	69.76 a	1422.71 a

C. The root length density

Under the condition of irrigated 120 mm during the winter wheat growing season, irrigation frequency and stages had significant effect on the vertical distribution of root length density (Fig.

2).Under the condition of irrigated only once, compared with T2, the root length density in T1 below the ground surface 20 cm and 50 cm were both significantly increased. Under the condition of irrigated 2 times, the root length density below the ground surface 30 cm in T3 was not significant difference from that in T1; however, below the ground surface 50 cm, the root length density both in T3 and T1 were significantly higher than that in T2. Thus, it was apparent that under the condition of irrigated 120 mm, irrigated at jointing stage resulted in a significant increase in root length density.

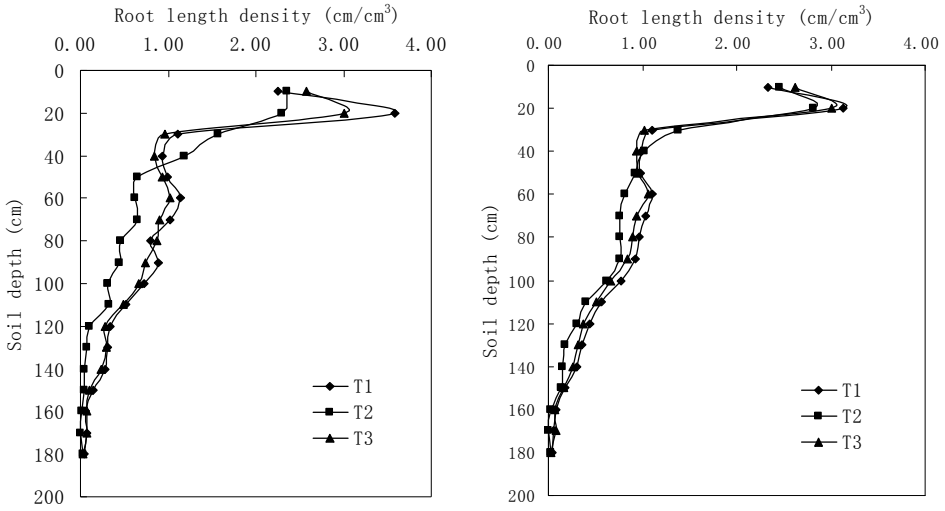

Figure.2 Effect of deficit irrigation on root length density at maturity in 2010－2011 and 2011－2012

D. Grain yield and yield components

Table 2 indicates that the grain yield and yield components were significantly affected by different irrigation regime in the both growing seasons. In 2010–2011, the grain yield in T3 was significantly higher than those in T1 and T2.The grain yield in T1 was not significant higher than that in T2. T3 resulted in the highest grain yield, which contributed to the spike numbers were significantly increased. Every treatment had not significant effect on kernel numbers and thousand kernel weight. In 2011–2012, the grain yield in T3 was significantly higher than those in T1 and T2. In yield components, the results showed that every irrigation treatment had significant effect on spike numbers. T3 resulted in the highest spike number, followed by T1, and the lowest was found in T2. Kernel numbers were not significantly different among any treatments. Compared with T1 and T3, thousand kernels weight in T2 was significantly increased. Hence, under the condition of irrigated 120 mm during the winter wheat growing season, irrigated 60 mm each at jointing and heading stages could improve spike number; hence, the grain yield could significantly increased.

T3	658.05 a	30.0 a	39.32 b	769.16 a

DISCUSSION

The result indicated that, in North China Plain, irrigated 120 mm during the growing season of winter wheat, irrigation frequency and stages could significantly alter the LAI above the ground surface, plant height, and dry matter accumulation; and that, the root length density under the ground surface could also alter significantly. The result showed that irrigated 60 mm each at jointing and heading stages of winter wheat significantly increase spike number, hence, the grain yield significantly enhanced.

Under field condition, the crops grain yield is determined by the ability of the canopy to intercept incoming radiation and radiation use efficiency [1]. As for crops grain yield, approximately 70–80% was the product of the photosynthetic matter of green organ produced after heading stage in the late growing season; this was approximately 60% more than that produced by the flag leaves and spikes. Hence, how to optimize canopy structure is a most important measure to increase crop community photosynthetic productivity [12]. Zhou et al.[20] found that the maize root characteristics were significantly corrected with photosynthetic ratio in ear leaves; moreover, the drought resistance in coeno-species was result from the coefficient of root and shoot. Hence, improving the root and shoot characteristic is very important to increase crops grain yield and drought resistance.

In North China Plain, water is limited. However, irrigation is mostly required during the growing season of winter wheat [7]. Hence, how to improve water use efficiency is the key to carry out agricultural sustainable development. Researches showed that irrigation patterns could significantly affect canopy structure of crops [8,16]. Through irrigation regulation and control, both the root systems of maize [14] and tomato [2] could be improved, as a result, the relationship between yield and water use efficiency was harmonized [4]. Therefore, maintaining reasonable canopy structure and increasing root absorbing ability is the central premise of guarantee crops grain yield. Crops water use efficiency is mainly determined by transpiration rate of leaves and water absorbing ability of roots; hence, the essence of high efficient water use in crops is the structure and function of root and canopy achieve optimum balance. Therefore, exploring the action mechanism of root and shoot equilibrium in assimilate distribution and water use, could provide theoretical basis and technical support for the development of saving water agriculture in North China Plain.
